DISPENSATORY

OF THE

UNITED STATES OF AMERICA.

BY

GEORGE B. WOOD, M.D.,

PROFESSOR OF MATERIA MEDICA AND PHARMACY IN THE UNIVERSITY OF PENNSYLVANIA,
ONE OF THE PHYSICIANS OF THE PENNSYLVANIA HOSPITAL, &c., &c.,

AND

FRANKLIN BACHE, M.D.,

PROFESSOR OF CHEMISTRY IN JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA, ONE OF THE
VICE-PRESIDENTS OF THE AMERICAN PHILOSOPHICAL SOCIETY, &c., &c.

FIFTH EDITION,

ENLARGED AND CAREFULLY REVISED.

PHILADELPHIA:

PUBLISHED BY GRIGG & ELLIOT,

NO. 9 NORTH FOURTH STREET.

1843.

Entered, according to the Act of Congress, in the year 1843,
By GEORGE B. WOOD, M.D., AND FRANKLIN BACHE, M.D.,
in the Clerk's Office of the District Court of the United States in and for
the Eastern District of Pennsylvania.

TO
JOSEPH PARRISH, M.D.,
AND
THOMAS T. HEWSON, M.D.,
AS
A MARK OF RESPECT
FOR
THEIR PRIVATE WORTH AND PROFESSIONAL CHARACTER,
AND AS
AN ACKNOWLEDGMENT
OF
THEIR NUMEROUS KIND OFFICES,
THIS WORK
IS RESPECTFULLY INSCRIBED
BY
THEIR FRIENDS,
THE AUTHORS.

PREFACE

TO

THE FIRST EDITION.

THE objects of a Dispensatory are to present an account of medicinal substances in the state in which they are brought into the shops; and to teach the modes in which they are prepared for use. The importance of these objects, and the general value and even necessity of a work of this nature, will not be disputed. It may, however, be a question, how far the wants of the medical and pharmaceutical community in this country are supplied by the Dispensatories already in circulation; and whether such a deficiency exists as to justify the offer of a new one to the public attention. The great merits of the works severally entitled "The Edinburgh New Dispensatory," and "The London Dispensatory," the former edited by the late Andrew Duncan, M. D., the latter by Anthony Todd Thomson, M. D., are well known wherever the English language is spoken. Founded, as they both are, upon the excellent basis laid by Lewis, they are nevertheless entitled, from the great addition of valuable materials, and the distinctive character exhibited in the arrangement of these materials, to be considered as original works; while the style in which they have been executed speaks strongly in favour of the skill and industry of their authors. But they were calculated especially for the sphere of Great Britain, and are too deficient in all that relates exclusively to this country, to admit of being received as standards here. In the history of our commerce in drugs, and of the nature, growth, and collection of our indigenous medical plants; in the chemical operations of our extensive laboratories; and in the modes of preparing, dispensing, and applying medicines, which have gradually grown into use among us; there is much that is peculiar, a knowledge of which is not to be gained from foreign books, and is yet necessary to the character of an accomplished American pharmacist. We have, moreover, a National Pharmacopœia, which requires an explanatory commentary, in order that its

precepts may be fully appreciated, and advantageously put into practice. On these accounts it is desirable that there should be a Dispensatory of the United States, which, while it embraces whatever is useful in European pharmacy, may accurately represent the art as it exists in this country, and give instruction adapted to our peculiar wants. It appears due to our national character, that such a work should be in good faith an American work, newly prepared in all its parts, and not a mere edition of one of the European Dispensatories, with here and there additions and alterations, which, though they may be useful in themselves, cannot be made to harmonize with the other materials so as to give to the whole an appearance of unity, and certainly would not justify the assumption of a new and national title for the book. Whether in the Dispensatories which have been published in the United States, these requisites have been satisfactorily fulfilled, it rests with the public to determine. That valuable treatises on *Materia Medica* and Pharmacy have been issued in this country, no candid person, acquainted with our medical literature, will be disposed to deny. In offering a new work to the medical and pharmaceutical professions, the authors do not wish to be considered as undervaluing the labours of their predecessors. They simply conceive, that the field has not been so fully occupied as to exclude all competition. The pharmacy of continental Europe is ground which has been almost untouched; and much information in relation to the natural history, commerce, and management of our own drugs, has lain ungathered in the possession of individuals, or scattered in separate treatises and periodicals not generally known and read. Since the publication of the last edition of our *National Pharmacopœia*, no general explanation of its processes has appeared, though required in justice both to that work and to the public. The hope of being able to supply these deficiencies may, perhaps, be considered a sufficient justification for the present undertaking.

The *Pharmacopœia* of the United States has been adopted as the basis of this Dispensatory. It is followed both in its general division of medicines, and in its alphabetical arrangement of them under each division. Precedence is, in every instance, given to the names which it recognises; while the explanations by which it fixes the signification of these names, are inserted in immediate connexion with the titles to which they severally belong. Every article which it designates is more or less fully described; and all its processes, after being literally copied, are commented on and explained whenever comment or explanation appeared necessary. Nothing, in fine, has been omitted,

which, in the estimation of the authors, could serve to illustrate its meaning or promote the ends which it was intended to subserve. This course of proceeding appeared to be due to the national character of the Pharmacopœia, and to the important object of establishing, as far as possible, throughout the United States, uniformity both in the nomenclature and preparation of medicines. In one particular, convenience required that the plan of the Pharmacopœia should be departed from. The medicines belonging to the department of MATERIA MEDICA, instead of being arranged in two divisions, corresponding with the *Primary* and *Secondary Catalogues* of that work, have been treated of indiscriminately in alphabetical succession; and the place which they respectively hold in the Pharmacopœia is indicated by the employment of the term *Secondary*, in connexion with the name of each of the medicines included in the latter catalogue.

But, though precedence has thus been given to the Pharmacopœia of the United States, those of Great Britain have not been neglected. The nomenclature adopted by the different British Colleges, and their formulæ for the preparation of medicines, have been so extensively followed throughout the United States, that a work intended to represent the present state of pharmacy in this country would be imperfect without them; and the fact that the writings of British physicians and surgeons, in which their own officinal terms and preparations are exclusively employed and referred to, have an extensive circulation among us, renders some commentary necessary in order to prevent serious mistakes. The Pharmacopœias of London, Edinburgh, and Dublin, have, therefore, been incorporated, in all their essential parts, into the present work. Their officinal titles are uniformly given—always in subordination to those of the United States Pharmacopœia, when they express the same object; but in chief, when, as often happens, no corresponding medicine or preparation is recognised by our national standard. In the latter case, if different names are applied by different British Colleges to the same object, that is generally preferred which is most in accordance with our own system of nomenclature, and the others are given as synonymes. The medicines directed by the British Colleges are all described, and their processes either copied at length, or so far explained as to be intelligible in all essential particulars.

Besides the medicinal substances recognised as officinal by the Pharmacopœias alluded to, some others have been described, which, either from the lingering remains of former reputation, or from recent reports in their favour, or from their important relation to medicines in general use, appear to have claims upon the attention of the phy-

sician and apothecary. Opportunity has, moreover, been taken to introduce incidentally brief accounts of substances used in other countries or in former times, and occasionally noticed in medical books; and that the reader may be able to refer to them when desirous of information, their names have been placed with those of the standard remedies in the Index.

In the description of each medicine, if derived immediately from the animal, vegetable, or mineral kingdom, the attention of the authors has been directed to its natural history, the place of its growth or production, the method of collecting and preparing it for market, its commercial history, the state in which it reaches us, its sensible properties, its chemical composition and relations, the changes which it undergoes by time and exposure, its accidental or fraudulent adulterations, its medical properties and application, its economical uses, and the pharmaceutical treatment to which it is subjected. If a chemical preparation, the mode and principles of its manufacture are indicated in addition to the other particulars. If a poison, and likely to be accidentally taken, or purposely employed as such, its peculiar toxicological effects, together with the mode of counteracting them, are indicated; and the best means of detecting its presence by reagents are explained.

The authors have followed the example of Dr. A. T. Thomson, in giving botanical descriptions of the plants from which the medicines treated of are derived. In relation to all indigenous medicinal plants, and those naturalized or cultivated in this country, the advantages of such descriptions are obvious. The physician may often be placed in situations, in which it may be highly important that he should be able to recognise the vegetable which yields a particular medicine; and the apothecary is constantly liable to imposition from the collectors of herbs, unless possessed of the means of distinguishing by infallible marks the various products presented to him. A knowledge of foreign medicinal plants, though of less importance, will be found useful in various ways, independently of the gratification afforded by the indulgence of a liberal curiosity in relation to objects so closely connected with our daily pursuits. The introduction of these botanical notices into a Dispensatory appears to be peculiarly appropriate; as they are to be considered rather as objects for occasional reference than for regular study or continuous perusal, and therefore coincide with the general design of the work, which is to collect into a convenient form for consultation all that is practically important in relation to medicines. The authors have endeavoured to preserve a due pro-

portion between the minuteness of the descriptions, and their value as means of information to the student; and, in pursuance of this plan, have generally dwelt more at length upon our native plants, than upon those of foreign growth: but in all instances, in which they have deemed any botanical description necessary, they have taken care to include in it the essential scientific character of the genus and species, with a reference to the position of the plant in the artificial and natural systems of classification; so that a person acquainted with the elements of botany may be able to recognise it when it comes under his observation.

In preparing the Dispensatory, the authors have consulted, in addition to many of the older works of authority, the greater number of the treatises and dissertations which have recently appeared upon the various subjects connected with Pharmacy, and especially those of the French writers, who stand at present at the head of this department of medical science. They have also endeavoured to collect such detached facts scattered through the various scientific, medical, and pharmaceutical journals, as they conceived to be important in themselves, and applicable to the subjects under consideration; and have had frequent recourse to the reports of travellers in relation to the natural and commercial history of foreign drugs. The occasional references in the body of the work will indicate the sources from which they have most largely drawn, and the authorities upon which they have most relied. In relation to our own commerce in drugs and to the operations of our chemical laboratories, they are indebted for information chiefly to the kindness of gentlemen engaged in these branches of business, who have always evinced, in answering their numerous inquiries, a promptitude and politeness which merit their warm thanks, and which they are pleased to have this opportunity of acknowledging.*

It has not been deemed necessary to follow the example of the British Dispensatories, by inserting into the work a treatise upon Chemistry under the name of Elements of Pharmacy. Such a treatise must necessarily be very meagre and imperfect; and, as systems of chemistry are in the hands of every physician and apothecary; would uselessly occupy the place of valuable matter of less easy access.

* The authors deem it proper to state that they are peculiarly indebted for assistance to Mr. Daniel B. Smith, president of the Philadelphia College of Pharmacy, to whom, besides much important information in relation to the various branches of the Apothecary's business, they owe the prefatory remarks on Pharmacy which are placed at the commencement of the second part of the work, and the several articles, in the *Materia Medica*, upon *Leeches*, *Litmus*, and the *Carbonate* and *Sulphate of Magnesia*.

The authors may perhaps be permitted to observe, in relation to themselves, that they have expended much time and labour in the preparation of the work; have sought diligently for facts from every readily accessible source; have endeavoured, by a comparison of authorities, and a close scrutiny of evidence, to ascertain the truth whenever practicable; and have exerted themselves to the extent of their abilities to render the Dispensatory worthy of public approbation, both for the quality and quantity of its contents, and the general accuracy of its statements. They are conscious, nevertheless, that in so great a multiplicity of details numerous errors and deficiencies may exist, and that the faults of undue brevity in some cases, and prolixity in others, may not have been entirely avoided: but they venture to hope that a candid public will make all due allowances; and they take the liberty to invite from all those who may feel interested in the diffusion of sound pharmaceutical knowledge, the communication of friendly suggestions or criticisms in relation to the objects and execution of the work.

Philadelphia, January, 1833.

PREFACE

TO THE

FIFTH EDITION.

IN the several editions of this Dispensatory subsequent to the first, such modifications of the original plan as set forth in the foregoing preface, and such additions and emendations have been made, as were thought calculated to increase the usefulness of the work, and to maintain it on a level with the advancing knowledge of the times. In the second edition, an Appendix was introduced containing notices and descriptions of numerous drugs, which, though not in general use, were possessed of some interest from their former or existing relations to Medicine and Pharmacy. In the third edition, the authors adopted the present plan of treating, in the body of the work, of those medicines and preparations exclusively which are recognised in the American and British Pharmacopœias, while all others deemed worthy of notice were placed in the Appendix; thus giving a precision to the arrangement which was before wanting. In the preparation of the fourth edition, many changes were rendered necessary by the previous publication of the revised London Pharmacopœia of 1836. But on no revision of the Dispensatory have the authors bestowed so much labour as on the present. The new editions of the United States and Edinburgh Pharmacopœias required comment; and the recent pharmacological treatises of Dr. Pereira and Dr. Christison, containing much original observation, and the Medical Flora of Dr. Lindley, not to speak of other valuable works in different departments of Materia Medica and Pharmacy, afforded a great mass of new material for selection and arrangement. The periodical medical press has also presented much that demanded notice; and the changes in the commerce in drugs, and the various modifications in pharmaceutical operations, resulting from increased experience and the advancement of science, called for careful personal examination and inquiry. It has been the aim of the authors, by pruning redundances and concentrating the new matter within the smallest possible space, to swell the Dispensatory as little as consisted with the great object of utility; but, with all their endeavours, they have been compelled to exceed the former limits by more than one hundred pages. In offering their work a fifth time to the public, they feel themselves justified in expressing their confident hope that it will be found, not less than formerly, to meet the wishes of the medical and pharmaceutical community.

Philadelphia, July, 1843.

ABBREVIATIONS EMPLOYED IN THE WORK.

U. S..—"THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA. By authority of the National Medical Convention, held at Washington, A. D. 1840."

Lond..—LONDON PHARMACOPŒIA, A. D. 1836.

Ed..—EDINBURGH PHARMACOPŒIA, A. D. 1841.

Dub..—DUBLIN PHARMACOPŒIA, A. D. 1826.

Off. Syn..—OFFICINAL SYNONYMES, or the titles employed by the Pharmacopœias with the accompanying explanations, when these titles are not given in chief.

Sex. Syst..—THE SEXUAL SYSTEM, or the artificial system of Linnæus, founded on the sexual organization of plants.

Nat. Ord..—THE NATURAL ORDER to which any particular genus of plants belongs. When not otherwise stated, it is to be understood that the natural orders referred to are those recognised by Professor Lindley, of the University of London, in his "Introduction to the Natural System of Botany."

Gen. Ch..—THE GENERIC CHARACTER, or scientific description of any particular genus of plants under consideration.

Off. Prep..—OFFICINAL PREPARATIONS; including all the preparations into which any particular medicine directed by the U. S. Pharmacopœia or the British Colleges enters. When the same preparation has received different names in the different Pharmacopœias, only one of these names is mentioned, and precedence is always given to that of the U. S. Pharmacopœia.

Sp. Gr..—SPECIFIC GRAVITY.

Equiv., or *Eq.*.—CHEMICAL EQUIVALENT, or the number representing the smallest quantity in which one body usually combines with others.

THE
DISPENSATORY
OF
THE UNITED STATES.

PART I.

MATERIA MEDICA.

THE *Materia Medica*, in its most comprehensive sense, embraces all those substances which are capable of making sanative impressions on the human system; but, as the term is employed in this work, it has a more restricted signification. The *Pharmacopœias* of the United States and Great Britain very appropriately arrange medicines in two distinct divisions, one including all those which are furnished immediately by nature, or thrown into commerce by the manufacturer; the other, those which are prepared by the apothecary, and are the objects of officinal directions. The former are enumerated under the title of "*MATERIA MEDICA*;" the latter, under that of "*PREPARATIONS*," or "*PREPARATIONS and COMPOSITIONS*." In Dispensatories, which may be considered as commentaries on the *Pharmacopœias*, the same arrangement is usually followed; and the authors of the present work adopt it the more willingly, as, independently of the weight of authority in its favour, it has the recommendation of being the most convenient. By this plan, all the directions which relate to the practical operations of the apothecary are collected in one place, and are thus more easily referred to, than if mixed indiscriminately with other matters, as they must be by any mode of arrangement which makes no distinction between the original medicinal substances and their preparations. Under the head of *Materia Medica*, therefore, in this Dispensatory, we treat of medicines in the state only in which they are produced by nature, or come into the hands of the apothecary. Of these medicines, such as are recognised by our National *Pharmacopœia* are most minutely described; but we consider also all that are included in the officinal catalogues of the British Colleges.

Another point in which we accord with the *Pharmacopœias*, is the alphabetical arrangement of the objects of the *Materia Medica*. As a Dispensatory is intended rather for reference than for regular perusal, it is important that its contents should be so disposed as to facilitate consultation. Medicines, in a work of this kind, are considered as independent objects, to be studied

separately, and without any reference to community of source, or similarity of character. Their scientific classification belongs to works which treat of them rather in their relations than their essential properties; and different systems have been adopted, according to the set of relations towards which the mind of the author has been especially directed. Thus, the naturalist classifies them according to the affinities of the several objects in nature from which they are derived; the chemist, according to their composition; the practitioner of medicine, according to their effects upon the system in a state of health and disease. But none of these classifications is without imperfections; and a simple alphabetical arrangement is decidedly preferable in every case in which the medicines are considered solely in their individual capacity. Yet, as it comes within the scope of this work to treat of their physiological and therapeutical effects, and as the terms by which these effects are expressed are also the titles of classes to which the medicines belong, it will not be amiss to present the reader with the outlines of a system of classification, by consulting which he will be enabled to ascertain the precise meaning we attach to the terms employed to designate the peculiar action of different medicinal substances.

Remedies are divided into general and local, the former acting on the whole system, the latter on particular parts or organs.

I. GENERAL REMEDIES include 1. ARTERIAL STIMULANTS, sometimes called INCITANTS, which, while they raise the actions of the system above the standard of health, exhibit their influence chiefly upon the heart and arteries; 2. NARCOTICS, which especially affect the cerebral functions, and are either *stimulant* or *sedative* according as they increase or diminish action; 3. ANTISPASMODICS, which, with a general stimulant power, exert a peculiar influence over the nervous system, exhibited in the relaxation of spasm, the calming of nervous irritation, &c.; without any special and decided tendency to the brain; 4. TONICS, which moderately and permanently exalt the energies of all parts of the frame, without necessarily producing any apparent increase of the healthy actions; and 5. ASTRINGENTS, which have the property of producing contraction in the living tissues with which they may come in contact.

II. LOCAL REMEDIES may be divided into four sections: *a. Those affecting the function of a part*, namely, 1. EMETICS, which act on the stomach, producing vomiting; 2. CATHARTICS, which act on the bowels, producing a purgative effect; 3. DIURETICS, which act on the kidneys, producing an increased flow of urine; 4. ANTILITHICS, which act on the same organs, preventing the formation of calculous matter; 5. DIAPHORETICS, which increase the cutaneous discharge; 6. EXPECTORANTS, which augment the secretion from the pulmonary mucous membrane, or promote the discharge of the secreted matter; 7. EMMENAGOGUES, which excite the menstrual secretion; 8. SIALAGOGUES, which increase the flow of saliva; and 9. ERRHINES, which increase the discharge from the mucous membrane of the nostrils: *b. Those affecting the organization of a part*, including 1. RUBEFACIENTS, which produce redness and inflammation of the skin; 2. EPISPASTICS or VESICATORIES, which produce a serous discharge beneath the cuticle, forming a blister; and 3. ESCHAROTICS or CAUSTICS, which destroy the life of the part upon which they act: *c. Those operating by a mechanical agency*, consisting of 1. DEMULCENTS, which lubricate the surface to which they are applied, and prevent the contact of irritating substances, or mingle with these and diminish their acrimony; and 2. EMOLLIENTS, which serve as vehicles for the application of warmth and moisture, at the same time excluding the air: *d. Those which act on extraneous matters con-*

tained within the organs, including 1. **ANTHELMINTICS**, which destroy worms, or expel them from the bowels; and 2. **ANTACIDS**, which neutralize acid, whether existing in the alimentary canal, or circulating with the blood.

It is believed that all substances employed as medicines, with the exception of a very few which are so peculiar in their action as scarcely to admit of classification, may be distributed without violence among the above classes. Some substances, however, in addition to the properties of the classes to which they are severally attached, possess others in common, which give them practical value, and authorize their association in distinct groups, not recognised in the system of classification, but constantly referred to in medical language. Thus we have **REFRIGERANTS**, which, when internally administered, diminish animal temperature; **ALTERATIVES**, which change, in some inexplicable and insensible manner, certain morbid actions of the system; and **CARMINATIVES**, which, by promoting contraction in the muscular coat of the stomach and bowels, cause the expulsion of flatus. It is common, moreover, to attach distinct names to groups of remedies, with reference to certain effects which are incident to the properties that serve to arrange them in some more comprehensive class. Thus **NARCOTICS** frequently promote sleep and relieve pain, and in relation to these properties are called **SOPORIFICS** and **ANODYNES**; and various medicines, which by diversified modes of action serve to remove chronic inflammation and enlargements of the glands or viscera, are called **DEOBSTRUENTS**. These terms are occasionally employed in the following pages, and are here explained, in order that the sense in which we use them may be accurately understood.

ABSINTHIUM. U. S., Lond., Ed.

Wormwood.

"The tops and leaves of *Artemisia Absinthium*." U. S. "*Artemisia Absinthium*." Lond. "*Herb of Artemisia Absinthium*." Ed.

Off. Syn. ARTEMISIA ABSINTHIUM. *Summitates florentes.* Dub.

Absinthe, Fr.; Gemeiner Wermuth, Germ.; Assenzio, Ital.; Artemisio Axenjo, Span.

ARTEMISIA. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ Senecionideæ. *De Cand.* Asteraceæ. *Lindley.*

Gen. Ch. *Receptacle* sub-villous or nearly naked. *Seed-down* none. *Calyx* imbricate, with roundish, converging scales. *Corollas of the ray* none. *Willd.*

Several species of *Artemisia* have enjoyed some reputation as medicines. The leaves of the *A. Abrotanum*, or southernwood, have but recently been discharged from the Pharmacopœias. They have a fragrant odour, a warm, bitter and nauseous taste; and were employed as a tonic, deobstruent, and anthelmintic. Similar virtues have been ascribed to the *A. Santonica*. The *A. pontica* has been occasionally substituted for common wormwood, but is weaker. The *A. vulgaris* or mugwort formerly enjoyed considerable reputation as an emmenagogue, and has recently come into some notice, in consequence of the recommendation of its root as a remedy in epilepsy by Dr. Burdach of Germany. For this purpose, it should be collected in autumn or early in the spring, and the side roots only dried for use. These should be powdered as they are wanted, the ligneous portion being rejected. The dose is about a drachm, to be administered in some warm vehicle in anticipation of the paroxysm, and to be repeated once or twice, at intervals of half an hour, till perspiration is produced, the patient being confined to bed. In the intervals, it may be given every second day. This is merely the revival of an old practice in Germany. The *A. vulgaris* of this country is thought by Nuttall to be a distinct species, and may not possess similar properties. In China, *moxa* is said to be prepared from the leaves of the *Artemisia Chinensis*, and *A. Indica*, which are for this reason ranked among the official plants by the Dublin College. (See *Moxa*.) The medicine known in Europe by the name of wormseed, is probably the product of different species of *Artemisia*. (See *Artemisia Santonica*.) But the only species which requires particular description is the *A. Absinthium*.

Artemisia Absinthium. Willd. *Sp. Plant.* iii. 1844; *Woodv. Med. Bot.* p. 54. t. 22. Wormwood is a perennial plant, with branching, round and striated or furrowed stems, which rise two or three feet in height, and are panicled at their summit. The lower portion of the stem lives several years, and annually sends up herbaceous shoots, which perish in the winter. The radical leaves are triply pinnatifid, with lanceolate, obtuse, dentate divisions; those of the stem, doubly or simply pinnatifid, with lanceolate, somewhat acute divisions; the floral leaves are lanceolate; all are hoary. The flowers are of a brownish-yellow colour, hemispherical, pedicelled, nodding, and in erect racemes. The florets of the disc are numerous, those of the ray few.

This plant is a native of Europe, where it is also cultivated for medical use. It is among our garden herbs, and has been naturalized in the mountainous districts of New England. The leaves and flowering summits are the parts employed, the larger parts of the stalks being rejected. They should be gathered in July or August, when the plant is in flower. They preserve their peculiar sensible properties long when dried.

Wormwood has a strong odour, and an intensely bitter, nauseous taste, which it imparts to water and alcohol. A dark green volatile oil, upon which the odour depends, is obtained by distillation. The constituents, according to Braconnot, are a very bitter, and an almost insipid azotized matter, an excessively bitter resinous substance, a green volatile oil, chlorophylle, albumen, starch, saline matters, and lignin. Among the saline substances, Braconnot found a combination of potassa with a peculiar acid, which he denominated *absinthic acid*. The substance formerly called *salt of wormwood* (*Sal Absinthii*) is impure carbonate of potassa, obtained by lixiviating the ashes of the plant.

Medical Properties and Uses. Wormwood was known to the ancients. It is highly tonic, and probably enters the circulation, as it is said to render the flesh and milk of animals fed with it bitter. It formerly enjoyed great reputation as a remedy in numerous complaints attended with a debilitated condition of the digestive organs, or of the system generally. Before the introduction of Peruvian bark, it was much used in the treatment of intermittents. It has also been supposed to possess anthelmintic virtues. At present, however, it is little used in regular practice on this side of the Atlantic. A narcotic property has been ascribed to it by some writers, in consequence of its tendency to occasion headach, and, when long continued, to produce disorder of the nervous system. This property is supposed to depend on the volatile oil, and therefore to be less obvious in the decoction than in the powder or infusion. In large doses, wormwood irritates the stomach, and excites the circulation. The herb is sometimes applied externally, by way of fomentation, as an antiseptic and discutient. The dose in substance is from one to two scruples; of the infusion made by macerating an ounce in a pint of boiling water, from one to two fluidounces.

ACACIA. *Sex. Syst.* Polygamia Monœcia. — *Nat. Ord.* Leguminosæ, *Trib.* Mimosææ.

This genus is one of those into which the old genus *Mimosa* of Linnæus was divided by Willdenow. The name *Acacia* was employed by the ancient Greeks to designate the gum-tree of Egypt, and has been appropriately applied to the new genus in which that plant is included.

Gen. Ch. HERMAPHRODITE. *Calyx* five-toothed. *Corolla* five-cleft, or formed of five petals. *Stamens* 4–100. *Pistil* one. *Legume* bivalve. *MALE.* *Calyx* five-toothed. *Corolla* five-cleft, or formed of five petals. *Stamens* 4–100. *Willd.*

Several species of *Acacia* contribute to furnish the gum Arabic of the shops. Those which have attracted most attention are the *A. vera* and *A. Arabica*, confounded together by Linnæus under the title of *Mimosa Nilotica*.

Acacia vera. Willd. *Sp. Plant.* iv. 1805; Hayne, *Darstel. und Beschreib.* &c. x. 34. This is a tree of middling size, with numerous scattered branches, of which the younger are much bent, and covered with a reddish-brown bark. The leaves are alternate and bipinnate, with two pairs of pinnæ, of which the lower are usually furnished with ten pairs of leaflets, the upper with eight. The leaflets are very small, oblong-linear, smooth, and supported upon very short footstalks. On the common petiole is a gland between each pair of pinnæ. Both the common and partial petiole are smooth. Two sharp spines, from a quarter to half an inch long, of the colour of the smaller branches, and joined together at their base, are found at the insertion of each leaf. The flowers are yellow, inodorous, small, and collected in globular heads supported upon slender peduncles, which rise from the axils of the leaves, in number from two to five together. The fruit is a smooth, flat, two-valved legume, divided by contractions, occurring at regular intervals, into several roundish portions, each containing a single seed. This species flourishes in Upper Egypt and Senegal, and is probably scattered over the whole intervening portions of the African continent. The *Acacia* of the Cape of Good Hope, considered by Sparrman and Thunberg as the *Mimosa Nilotica* of Linn., and hence treated by some authors as identical with the present species, appears to be distinct, and has received the name of *Acacia Karroo*. It exudes a gum, which is collected at the Cape.

A. Arabica. Willd. *Sp. Plant.* iv. 1805; Hayne, *Darstel. und Beschreib.* x. 32.—*Acacia Nilotica*, Delil. *Ill. flor. de l'Egypt.* p. 79.—*Acacia vera*. Vesling. *Ægypt.* p. 8. This species, though often little more than a shrub, attains in favourable situations the magnitude of a considerable tree, being sometimes forty feet high, with a trunk a foot or more in diameter. The leaves are alternate and doubly pinnate, having from four to six pairs of pinnæ, each of which is furnished with from ten to twenty pairs of minute, smooth, oblong-linear leaflets. The common petiole has a gland between the lowest pair of pinnæ, and often also between the uppermost pair. Both the common and partial petiole, as well as the young branches, are downy. The thorns are straight, and disposed as in the former species. The flowers are also arranged as in the *A. vera*, and the fruit is of a similar shape. The *A. Arabica* is perhaps the most widely diffused of the gum-bearing species. It grows in Upper and Lower Egypt, Senegal, and other parts of Africa, flourishes also in Arabia, and is abundant in Hindostan, where its gum is used for food by the natives.

Besides the two species above described, the following afford considerable quantities of gum:—The *A. Senegal*, a small tree, inhabiting the hottest regions of Africa, and said to form vast forests in Senegambia; the *A. gummiifera*, seen by Broussonet in Morocco near Mogador; the *A. Ehrenbergiana*, a shrub six or eight feet high, named in honour of the German traveller Ehrenberg, who observed it in the deserts of Lybia, Nubia, and Dongola; the *A. Seyal*, growing in the same countries with the last mentioned species, and also in Upper Egypt and Senegambia; the *A. Adansonii* of the *Flore de Sénégal*, which is said to contribute a portion of the Senegal gum; and the *A. tortilis*, which sometimes attains the height of sixty feet, and inhabits Arabia Felix, Nubia, Dongola, and the Lybian desert. It is highly probable that gum is obtained also from other species not hitherto described, growing in the hot latitudes of Africa. The *A. decurrens* and *A. floribunda*, natives of New Holland, yield by exudation a tolerably pure gum, which has not yet, however, been extensively collected. Other trees, moreover, not belonging to the genus, afford a similar

product, especially the *Feronia elephantum* of Hindostan, the gum of which, according to Ainslie, is used for medical purposes by all the practitioners of Lower India.

The gum-bearing Acacias are all thorny or prickly trees or shrubs, calculated by nature for a dry and sandy soil, and flourishing in deserts where few other trees will grow. We are told that camels, attached to the caravans, derive from them their chief sustenance in many parts of those desolate regions in which Africa abounds. In these situations they have a stunted growth, and present a bare, withered, and uninviting aspect; but in a favourable situation, as on the banks of rivers, they are often luxuriant and beautiful.

Their bark and unripe fruit contain tannin and gallic acid, and are sometimes used for tanning leather. An extract was formerly obtained from the immature pods of the *A. Arabica* and *A. vera*, by expression and inspissation. It was known to the ancients by the name of *acaciæ veræ succus*, and was highly lauded by some of the Greek medical writers. It is at present little used, though described in most of the European works on Pharmacy. It is a solid, heavy, shining, reddish-brown substance, of a sweetish, acidulous, styptic taste, and soluble in water. Its virtues are probably those of a mild astringent. On the continent of Europe, a preparation is said to be usually substituted for it called *acacia nostras*, obtained by expression and inspissation from the unripe fruit of the *Prunus spinosa*, or wild plum tree.

The gum of the Acacias exudes spontaneously from the bark of the trunk and branches, and hardens on exposure; but incisions are sometimes made in order to facilitate the exudation. This is supposed by some to be favoured by disease, and it is stated by Jackson, that, in Morocco, the greatest product is obtained in the driest and hottest weather, and from the most sickly trees. An elevated temperature appears to be essential; for in cooler climates, though the tree may flourish, it yields no gum. According to Ehrenberg, the varieties in the colour and other characters of the gum do not depend upon difference in the species of the plant. Thus, from the same tree, the gum will exude frothy or thick, and clear or dark coloured, and will assume, upon hardening, different shapes and sizes; so that the pieces, when collected, require to be assorted before being delivered into commerce.

Commercial History and Varieties. The most common varieties of this drug are the *Turkey*, the *Barbary*, the *Senegal*, and the *India Gum*; to which may be added the *Cape Gum*.

1. **TURKEY GUM.** Gum Arabic was formerly procured, chiefly, if not exclusively, from Egypt and the neighbouring countries; and much is still obtained from the same sources. It is collected in Upper Egypt, Nubia, and Darfur, whence it is taken down the Nile to Alexandria. A considerable quantity is also brought to the same port from Arabia. We obtain it in this country through Smyrna, Trieste, Marseilles, or some other entrepot of the Mediterranean commerce. Two varieties of the gum have long been noticed, one more or less coloured, the other white, which were formerly, and, on the continent of Europe, are still distinguished by the titles of *gum gedda*, and *gum turic*, derived from the ports of the Red Sea, Jidda and Tor, from which the varieties were erroneously supposed to be respectively exported. The gum from Egypt is commonly known to our druggists by the name of *Turkey gum*, and is the kind with which the apothecaries are usually supplied. Though interspersed with roundish pieces of various sizes, it consists chiefly of small, irregular fragments, which are commonly whitish, or slightly tinged with yellow or reddish-yellow. It is on the

whole lighter coloured, more brittle, more readily soluble, and much freer from impurities than the other commercial varieties, and contains much of that form of gum Arabic, which is characterized by innumerable minute fissures pervading its substance, and impairing its transparency. The best comes in cases.

2. BARBARY GUM. Much gum Arabic is at present obtained from Barbary; and Mogador, a port of Morocco, is the chief entrepot of the trade. According to Jackson, the natives call the tree which affords it *attaleh*. They gather it in the months of July and August, when the weather is hot and very dry. Two kinds are brought to Mogador, one from the neighbouring provinces, the other by caravans from Timbuctoo. This may account for the fact that the Barbary gum in part resembles the Turkey, in part the Senegal. When first deposited in the warehouses, it has a faint smell, and makes a crackling noise, occasioned by the spontaneous rupture of the small masses as they become more dry. The Barbary gum is exported in casks, and reaches the U. States through the route of English commerce.

3. SENEGAL GUM. This variety was first introduced into Europe by the Dutch. The French afterwards planted a colony on the western coast of Africa, and took possession of the trade; but since the last great European war, it has been largely shared by the English. St. Louis, at the mouth of the Senegal, and Portendic, considerably further north, are the ports in which the commerce in gum has chiefly centered. Immense forests of the Acacia exist at some distance in the interior. These are composed chiefly of two different trees, called by the natives *verreck* or *nereck*, and *nebuel* or *nebued*, the former of which yields a white gum, the latter a red. These are probably distinct species, the *verreck* being, according to M. Rain, the *A. vera*, and the *nebuel* the *A. Senegal*. According to Adanson, there are several other species in the neighbourhood which yield gum. In the month of November the juice begins to exude from the trees. The dry winds, which prevail after the rainy season, cause the bark to crack; the juice flows out, and hardens in masses, which are often as large as a pigeon's egg, and sometimes, according to M. Rain, as large as the egg of the ostrich. At this period the Moors and negroes proceed to the forests in caravans, collect the gum in leather sacks, and convey it to the coast, where they exchange it for British goods. Senegal gum is imported into the United States chiefly from Bordeaux. It is usually in roundish or oval unbroken pieces, of various sizes, sometimes whitish, but generally yellowish or reddish, or brownish-red, larger than those of the Turkey gum, less brittle and pulverizable, and breaking with a more conchoidal fracture. The French give the name of *Gum Galam* (*Gomme de Galam*) to a variety consisting of pieces more irregular in shape, often angular and broken, and mixed with small fragments, so as to resemble Turkey gum in appearance. (*Guibourt*.)

4. INDIA GUM. Considerable quantities of gum are imported into this country from India. Ainslie states that it is derived from the *A. Arabica*; and it is not improbable that much of it is taken to Calcutta in the Arab vessels from the ports of the Red Sea. It is in pieces of various size, colour, and quality, some resembling the broken fragments of the Turkey gum, though much less chinky; others large, roundish, and tenacious, like the Senegal. Its taste is sweeter than that of the other varieties. It is usually much contaminated, containing, besides the genuine gum Arabic, portions of a different kind of gum, having the characteristic properties of that known by the name of Bassora. This is distinguished by its insolubility in water, with which, however, it unites, swelling up, and forming a soft viscid mass. It owes its properties to the presence of *bassorin*. The pieces of this gum

bear a considerable resemblance to those of the genuine article, and may easily escape detection. Their want of solubility, however, is a ready test. More or less of a similar substance is found in the parcels of gum Arabic from other sources; and we have seen some said to have come from Barbary, chiefly composed of it. Besides this impurity in the India gum, there are often others more readily detected. Among these, we have observed a yellowish-white resinous substance, which has the sensible properties of the turpentine. If proper care be used in assorting this commercial variety, it may be employed for all the purposes of good gum Arabic. The *India gum* is brought into this country partly from Calcutta, partly by way of England. It usually comes in large cases. We have seen a parcel of gum said to have come directly from the Red Sea, enclosed in large sacs made of a kind of matting, and bearing a close resemblance to the gum from Calcutta, except that it was more impure, and contained numerous large, irregular, very brittle masses, not much less than the fist in size.

5. CAPE GUM. Pereira mentions that gum has recently been imported into Great Britain from the Cape of Good Hope, where it is collected probably from the *Acacia Karroo*, which grows abundantly on the banks of the Gariep and in other parts. It is of a pale yellow colour, in tears or fragments, and is considered an inferior variety. None of it probably reaches this country.

General Properties. Gum Arabic is in roundish or amorphous pieces, or irregular fragments of various sizes, more or less transparent, hard, brittle, pulverizable, and breaking with a shining fracture. It is usually white, or yellowish-white; but frequently presents various shades of red, and is sometimes of a deep orange or brownish colour. It is bleached by exposure to the light of the sun. In powder it is always more or less purely white. It is inodorous, has a very feeble slightly sweetish taste, and when pure, dissolves wholly away in the mouth. The specific gravity varies from 1.31 to 1.48. (*Berzelius.*) Gum Arabic consists essentially of a peculiar proximate principle of plants usually called *gum*, but for which the name of *arabin*,*

* Much confusion has existed in the use of the word *gum*, which has been employed to express various concrete vegetable juices, and, at the same time, a peculiar proximate principle of plants. It is now proposed to restrict the term to the former of these applications, and to designate the principle alluded to by a distinct name. Within a few years the subject of the gums has been investigated by M. Guérin, who has repeated and corrected the experiments of former chemists, and thrown new light upon the nature of these substances. Several of the facts mentioned in the text have been derived from his memoir, published in the *Ann. de Chim. et de Phys.* t. XLIX. p. 248. M. Guérin considers as characteristic of gums, the property of affording mucic acid, when acted on by nitric acid. He recognises in the different gums three distinct proximate principles; namely, 1. *arabin*, or the pure gum of chemical writers, which is the essential constituent of gum Arabic in all its varieties; 2. *bassorin*, which enters largely into the composition of Bassora gum and tragacanth; and 3. *cerasin*, which constitutes the portion of cherry gum insoluble in cold water. Of arabin sufficient is said in the text. Bassorin will be treated of under the head of Bassora gum. (See *Appendix*.) Of *cerasin* it may be proper to say a few words in this place. The gums which exude from the cherry, apricot, peach, and plum trees, and which the French call *gomme du pays*, appear to be identical in composition, consisting of a portion soluble in cold water, which is arabin, and a portion insoluble, which was formerly thought to be the same with bassorin, but has been proved by M. Guérin to be different, and is appropriately denominated *cerasin*. This principle is colourless, semitransparent, tasteless, inodorous, uncrystallizable, insoluble in alcohol, insoluble in cold water, in which it softens and swells a little, and convertible by the action of boiling water into arabin, with which it appears to be isomeric. In this last property it differs materially from bassorin, which is not changed by boiling water. M. Guérin suggests that the natural heat of the climate in tropical countries produces the same effect upon the exuded gums as artificial heat in colder regions, and that consequently the acacia gum consists chiefly of arabin.—*Note to third edition.*

originally proposed by Chevreul, has been adopted by the French chemists. In describing its chemical relations, therefore, we describe those of the principle alluded to. Water, either cold or hot, dissolves it, and forms a viscid solution called mucilage, which, when evaporated, yields the gum unchanged. (See *Mucilago Acaciæ*.) It is insoluble in alcohol, ether, and the oils; and alcohol precipitates it from its aqueous solution. The diluted acids dissolve it, but not more freely than water. The concentrated acids decompose it. Triturated with sulphuric acid, at ordinary temperatures, it is converted into a substance similar to the gummy product which results from the action of the same acid on linen rags and saw-dust. Heated with concentrated sulphuric acid, it is decomposed with the evolution of carbon. The diluted acid, when boiled with it, gives rise to the formation of a saccharine substance. Strong nitric acid converts it into mucic acid, and at the same time produces oxalic and malic acids. It combines with several of the salifiable bases. With the alkalies and earths it forms soluble compounds. By the subacetate of lead it is precipitated from its solution, in the form of a white insoluble compound of gum and protoxide of lead; and a delicate test of its presence in any liquid is thus afforded. It enters into combination with several salts. A solution of borax coagulates it. When added to a solution of silicate of potassa, it precipitates a compound of gum, potassa, and silica, while a compound of gum and potassa remains dissolved. Its solution yields a precipitate with nitrate of mercury, and forms a brown, semi-transparent jelly, when mixed with a strong solution of sesquichloride of iron. In solution, it unites with sugar; and the liquid, when evaporated, yields a transparent, solid substance, which is not susceptible of crystallization.

Gum Arabic undergoes no change by time when kept in a dry place. Its aqueous solution, if strong, remains for a considerable length of time unaltered, but ultimately becomes sour in consequence of the production of acetic acid. At a temperature between 300° and 400° , the gum becomes soft, and may be drawn into threads. At a red heat it is decomposed, yielding, among other substances, a minute proportion of ammonia. When burnt, it leaves about three per cent. of ashes, consisting, according to Guérin, of the carbonates of potassa and of lime, a little phosphate of lime, chloride of potassium, oxide of iron, alumina, magnesia, and silica. The lime exists in the gum combined with an excess of malic acid, which gives to its solution the property of reddening litmus paper. Besides pure gum or arabin, gum Arabic contains a very small proportion of some azotized body, which is thought to occasion a slight opalescence in its solution, several saline substances, and a considerable quantity of uncombined water, amounting, according to Guérin, to 16 or 17 per cent. Pure gum may be obtained by treating the compound of gum and protoxide of lead with sulphuretted hydrogen. Its ultimate constituents are carbon, oxygen, and hydrogen; but the proportions are stated somewhat differently by different chemists. Thus its formula has been variously given, $C_{13}H_{13}O_{12}$; $C_{12}H_{10}O_{10}$; and $C_{12}H_{11}O_{11}$.

The properties above described belong to gum Arabic generally. There are, however, pharmaceutic varieties which present differences deserving notice. 1. *Gum that is transparent and readily soluble.* This constitutes by far the greater portion of the commercial varieties distinguished by the names of Turkey gum and Senegal gum. It is characterized by its transparency, ready solubility, and the comparatively slight degree of thickness and viscosity of its solution. Under this head may be included the *gomme blanche fendillée* of Guibourt, and other French writers. It is distinguished by the whiteness and deficient transparency of the pieces, attributable to the minute cracks or fissures with which

they abound, and which render them very brittle and easily pulverizable. This peculiar structure is generally ascribed to the influence of solar heat and light; but is conjectured by Hayne to arise from the exudation of the juice in the frothy state noticed by Ehrenberg. Though the pieces are somewhat opaque, each of the minute fragments into which they may be broken is perfectly transparent and homogeneous. This variety, in consequence of its prompt and entire solubility, is usually preferred for medical use, and for most purposes in pharmacy. 2. *Gum less transparent and less soluble.* Guibourt has proposed for portions of this gum the name of *gomme pelliculée*, from the circumstance that the masses are always apparently covered, on some part of their surface, by a yellowish opaque pellicle. Other portions of it have a mamillary appearance on the surface. Its transparency is less perfect than that of the former variety; it is less freely and less completely dissolved by water, and forms a more viscid solution. It melts with difficulty in the mouth; and adheres tenaciously to the teeth. It is found in all the commercial varieties of gum, but least in that from Egypt. Its peculiarities may probably be ascribed to variable proportions of *bassorin* associated with the soluble *arabin*. Between these two varieties of gum there are insensible gradations, so that it would be difficult always to classify the specimens which may come under notice.

Impurities and Adulterations. In parcels of gum Arabic there are sometimes pieces of a dark colour, opaque, and incorporated with ligneous, earthy, or other impurities. The inferior are often mixed with or substituted for the better kinds, especially in powder; and portions of insoluble gum, bdellium, and other concrete juices of unknown origin, are found among the genuine. Flour or starch is sometimes fraudulently added to the powder, but is easily detected by the blue colour which it produces with solution of iodine. In consequence of the impurities, and difference in quality, gum Arabic should generally be assorted for pharmaceutical use.

Medical Properties and Uses. This gum is used in medicine, chiefly as a demulcent. By the viscosity of its solution, it serves to cover and sheathe inflamed surfaces; and by blending with and diluting irritating matters, tends to blunt their acrimony. Hence it is advantageously employed in catarrhal affections and irritation of the fauces, by being held in the mouth and allowed slowly to dissolve. Internally administered it has been found especially useful in inflammatory affections of the gastric and intestinal mucous membrane; and its employment has even been extended to similar affections of the lungs and urinary organs. Whether it is beneficial in the latter cases in any other manner than by the dilution resulting from its watery vehicle, is a doubtful point. By some physicians it is thought to possess a positively sedative influence over the action of inflamed surfaces to which it is applied in the state of solution. As an article of diet in febrile cases, and others requiring an adherence to a very rigid regimen, it is perhaps superior to almost any other substance. If not positively sedative, it is certainly not in the least irritating, while it is sufficiently nourishing to prevent the injurious action of the organs upon themselves. Its nutritive properties have been denied; but the fact of their existence rests on incontrovertible evidence. The Moors and negroes live on it almost exclusively during the period of its collection and conveyance to market; the Bushman Hottentots, in times of scarcity, support themselves upon it for days together; and we are told that the apes of South Africa are very fond of it. Six ounces a day are said to be sufficient to sustain life in a healthy adult. In many cases of disease, its solution may with propriety constitute the exclusive drink and food of the patient. It is best prepared by dissolving an ounce of the gum

in a pint of boiling water, and allowing the solution to cool. In pharmacy, gum Arabic is extensively used for the suspension of insoluble substances in water, and for the formation of pills and troches.

ACETOSELLA. *Lond.*

Wood-sorrel.

“*Oxalis Acetosella.*” *Lond.*

Oseille de bucheron, *Surelle, Fr.*; Sauerklee, *Germ.*; Alleloja, *Ital.*; Acederilla, *Span.*

OXALIS. *Sex. Syst.* Decandria Pentagynia.—*Nat. Ord.* Oxalidaceæ.

Gen. Ch. *Calyx* five-leaved. *Petals* five, connected by the claws. *Stamens* unequal, the five shorter exterior ones connected at the base. *Capsules* opening elastically at the corners, five angled. *Seeds* covered with an arillus. *Pursh.*

Oxalis Acetosella. Willd. *Sp. Plant.* ii. 780.; Woodv. *Med. Bot.* p. 563. t. 201. The wood-sorrel is a small perennial, herbaceous, stemless plant, with numerous radical leaves, which are all ternate, and supported upon slender hairy petioles. The leaflets are obcordate, entire, hairy, of a yellowish-green colour, but frequently purplish on their under surface. The scape or flower-stalk, which usually exceeds the petioles in length, is furnished with two scaly bractes near the middle, and terminates in a large white, or flesh-coloured flower, marked with red streaks. The styles are of the same length with the inner stamens.

This plant is a native both of Europe and N. America. In this country it is found chiefly in the mountainous regions of the interior. It selects shady places, such as woods, groves, and hedges, and flowers in May. Other indigenous species of *Oxalis*, more widely diffused than the *O. Acetosella*, might be substituted for it without disadvantage, as they possess similar properties. They all have ternate leaves with obcordate leaflets, and, with the single exception of the *O. violacea*, bear yellow flowers. The whole herbaceous portion may be used.

Properties. Wood-sorrel is without smell, and has a pleasant sour taste. It owes its acidity to the *binoxalate of potassa*, which is sometimes separated for use, and sold under the name of *salt of sorrel*. This is prepared, in Switzerland and Germany, from different species of *Oxalis* and *Rumex*, by the following process. The plants, previously bruised, are macerated for some days in water, and then submitted to pressure. The liquid thus obtained is mixed with clay and occasionally agitated for two days. At the end of this time, the clear liquor is decanted, and evaporated so that crystals may form when it cools. These are purified by solution and a new crystallization. Five hundred parts of the plant afford four parts of the acidulous salt. The same salt may be prepared by exactly neutralizing with potassa one part of oxalic acid in solution, then adding one part more of the acid, and evaporating the solution so that it may crystallize upon cooling. Binoxalate of potassa is in rhomboidal crystals, of a sour, pungent, bitterish taste, soluble in forty parts of cold and six parts of boiling water (*Kane*), and unalterable in the air. It contains 72.48 parts or two equivalents of oxalic acid, 47.5 parts or one equivalent of potassa, and 18 parts or two equivalents of water. The *quadroxalate of potassa* is often substituted

for the binoxalate. It is prepared in the same manner, except that, instead of one part, three parts of the acid are added to the original portion neutralized by potassa. Both salts are kept in the shops under the names of *salt of sorrel* and *essential salt of lemons*, and are employed for removing iron mould and ink stains from linen, and sometimes as a test for lime. Both are poisonous, though in a less degree than uncombined oxalic acid.

Medical Properties. This and other species of sorrel are refrigerant; and their infusion, or a whey made by boiling them in milk, may be used as a pleasant drink in febrile and inflammatory affections. A solution of the binoxalate of potassa is used on the continent of Europe as a substitute for lemonade. The fresh plant, eaten raw, is said to be useful in scorbutic cases. W.

✱ ACETUM. U. S., Lond.

Vinegar.

“Impure dilute acetic acid prepared by fermentation.” *U. S.* “Acetum. Fermentatione paratum.” *Lond.*

Off. Syn. ACETUM BRITANNICUM. ACETUM GALLICUM. *Ed.*; ACETUM VINI. *Dub.*

Vinaigre, Fr.; *Essig, Germ.*; *Aceto, Ital.*; *Vinagre, Span.*

Vinegar is a sour liquid, the product of the acetous fermentation. Viewed chemically, it is a very dilute solution of acetic acid, containing foreign matters. (See *Acidum Aceticum*.)

The acetous fermentation can be induced in all liquors which have undergone or are susceptible of the vinous fermentation. Thus sugar and water, saccharine vegetable juices, infusion of malt, cider, and wine may be converted into vinegar, if subjected to the action of a ferment, and exposed, with access of air, to a temperature between 75° and 90°.

In different countries, different liquors are used for conversion into vinegar. In France and other wine countries, wine is employed; in Britain, infusion of malt; and in the United States, for the most part, cider. For the use of the white lead manufacturer, it has, of latter years, been extensively made from potatoes.

The method pursued in making wine vinegar at Orleans, in France, where it is manufactured in the greatest perfection, is as follows. Casks are employed of about the capacity of 88 wine gallons, those being preferred which have been previously used for a similar purpose. They are placed upright in three rows, one above another; each cask having an opening at the top of about two inches in diameter. In summer, no artificial heat is used; but in winter, the temperature of the manufactory is maintained at about 68°. The wine intended to be converted into vinegar is kept in separate casks, containing beech shavings, on which the lees are deposited. Twenty-two gallons of good vinegar, boiling hot, are first introduced into each vinegar cask, and at the end of eight days, about two gallons of the wine, drawn off clear, are added; and the same quantity is added every eight days, until the casks are full. After this, the vinegar takes about fifteen days to form. At the end of that time, only half the contents of each cask is drawn off; and it is filled up again by the addition of two gallons of wine every eight days as at first. In some cases, however, the quantity of wine added, and the intervals between the successive additions, are greater or less than those here indicated; the variations in this respect depending upon the progress of the fermentation. To determine this point, the vinegar makers plunge a

stave into the cask; and if, upon withdrawing it, they find it covered with froth, they judge that the fermentation is going on properly, and, accordingly, add more wine.

When the infusion of malt is employed, the process is as follows. The infusion, when properly cooled, is put into large and deep fermenting-tuns, where it is mixed with yeast, and kept in fermentation for four or five days. The liquor is now distributed into smaller vessels; placed in a room heated by means of a stove, and kept there for about six weeks, or until the whole is soured. It is then transferred to common barrels, which are placed in the open air, the bung-holes being simply covered with a tile to keep out the rain; in which situation they are allowed to remain for several months, or until perfect vinegar is formed. The process is then completed in the following manner. Large tuns are prepared, with false bottoms, on which is put a quantity of the refuse of raisins and other fruit, technically called *rape*. These tuns are worked in pairs, one being completely filled with the vinegar from the barrels, and the other only three-fourths filled. In the latter, the fermentation takes place more rapidly; and the process is rendered more active alternately in one or the other tun, by filling up each daily from the other, until the process is completed.

In the United States, cider is the principal liquid from which vinegar is prepared. When it is made on a large scale from cider, the liquor is placed in barrels with their bung-holes open, which are exposed during the summer to the heat of the sun. The acetification is completed in the course of about two years. The progress of the fermentation, however, must be watched; and as soon as perfect vinegar is formed, it should be racked off into clean barrels. Without this precaution, the acetous fermentation would run into the putrefactive, and the whole of the vinegar be spoiled. The early cider is not so good for conversion into vinegar as the late, in consequence of the abundance of malic acid in the former; for it must be recollected that, in cider, the malic acid is not the subject matter of the acetous fermentation, but the alcohol which it contains as a vinous liquor.

Vinegar is now made by the improved *German method*, by which the time consumed in its formation is greatly abridged. A mixture is made of one part of alcohol of 80 per cent., four to six parts of water, and one-thousandth of honey or extract of malt to act as a ferment. This mixture is allowed to trickle through a mass of beech shavings, previously steeped in vinegar, and contained in a deep oaken tub, called a *vinegar generator*. The tub is furnished, near the top, with a shelf, perforated with numerous small holes, which are loosely filled with packthread about six inches long, prevented from slipping through by a knot at one end. The alcoholic mixture, first heated to between 75° and 83° , is placed on this shelf and slowly percolates the beech shavings, whereby it becomes minutely divided. It is essential to the success of the process that a current of air should pass through the tub. In order to establish this current, eight equidistant holes are pierced near the bottom of the tub, forming a horizontal row, and four glass tubes are inserted vertically in the shelf, of sufficient length to project above and below it. The air enters by the holes below and passes out by the tubes. The contact of the air with the minutely divided liquid rapidly promotes the acetification, which consists, essentially, in the oxidation of the alcohol. During the process the temperature rises to 100° or 104° , and remains nearly stationary while the process is going on favourably. The liquid is drawn off by a discharge pipe near the bottom, and must be passed three or four times through the tub, before the acetification is completed, which generally occupies from twenty-four to thirty-six hours.

Vinegar may be clarified, without injuring its aroma, by throwing about a tumbler full of boiling milk into from fifty to sixty wine gallons of the liquid, and stirring the mixture. This operation has the effect, at the same time, of rendering red vinegar pale.

The series of changes which occur during the acetous fermentation is called *acetification*. During its progress, there is a disengagement of heat; the liquor absorbs oxygen, becomes turbid, and filaments form, which are observed to move in various directions, until, finally, the fermentation being completed, they are deposited in a mass of a pultaceous consistence. The liquor now becomes transparent, its alcohol has disappeared, and acetic acid has been formed in its place. How then is this change of alcohol into acetic acid effected? Liebig supposes that it takes place in consequence of the formation of a new substance, called aldehyd, into which the alcohol is changed by the loss of part of its hydrogen. The alcohol, consisting of four equiv. of carbon, six of hydrogen, and two of oxygen, loses two equiv. of hydrogen through the influence of the atmosphere, and becomes aldehyd, composed of four equiv. of carbon, four of hydrogen, and two of oxygen. This, by the absorption of two equiv. of oxygen, becomes four equiv. of carbon, four of hydrogen, and four of oxygen; that is, hydrated acetic acid. Thus the conversion of alcohol into acetic acid consists in, first, the removal of two equiv. of hydrogen, and afterwards the addition of two equiv. of oxygen. *Aldehyd* is a colourless, very inflammable, ethereal liquid of the density of 0.79. It absorbs oxygen with avidity, and is thus converted into acetic acid, as just stated. Its name alludes to its relation to alcohol, *alcohol dehydrogenated*.

Properties. Vinegar, when good, is of an agreeable penetrating odour, and pleasant acid taste. The better sorts have a grateful aroma, which is probably due to the presence of an ethereal substance, perhaps acetic ether. The colour of vinegar varies from pale yellow to deep red. When long kept, particularly if exposed to the air, it becomes muddy and ropy, acquires an unpleasant smell, putrefies, and loses its acidity. This result may, in a good measure, be prevented by boiling it for a few minutes, so as to coagulate and separate the gluten, and immediately transferring it to bottles, which must be well corked.

The essential ingredients of vinegar are *acetic acid* and *water*, but besides these it contains various other substances, derived from the particular vinous liquor from which it may have been prepared. Among these may be mentioned, colouring matter, gum, starch, gluten, sugar, a little alcohol, and frequently malic and tartaric acids, with minute portions of alkaline and earthy salts. According to the U. S. Pharmacopœia, vinegar should be free from sulphuric acid, and of such a strength that a fluidounce would be saturated by about thirty-five grains of crystallized bicarbonate of potassa.

In the last Edinburgh Pharmacopœia (1841), two kinds of vinegar have been made official, malt vinegar and wine vinegar, under the names of *British vinegar* and *French vinegar*. In this Pharmacopœia the former is stated to vary in density from 1.006 to 1.019, the latter from 1.014 to 1.022. Specific gravity, however, is not an accurate index of the strength of vinegar.

Malt vinegar has a yellowish-red colour. That of British manufacture usually contains sulphuric acid, which the manufacturer is allowed by law to add in a proportion not exceeding one-thousandth part. The strongest kind, called proof vinegar, contains from 4.6 to 5 per cent. of acetic acid. The Edinburgh College does not recognise this impurity, although sanctioned by the British laws, and, therefore, rejects the vinegar if it give evi-

dence of the presence of free sulphuric acid. On the contrary, the London College admits the vinegar if the precipitate of sulphate of baryta, obtained on the addition of a solution of chloride of barium, does not exceed 1.14 grains to the fluidounce (*Imperial measure*).

Wine vinegar is nearly one-sixth stronger than pure malt vinegar. It is of two sorts, the white and the red, according as it is prepared from white or red wine. *White wine vinegar* is usually preferred, and that made at Orleans is the best. *Red wine vinegar* may be deprived of its colour and rendered limpid, by being passed through animal charcoal. According to the Edinburgh Pharmacopœia, wine vinegar may be distinguished from malt vinegar by the addition of ammonia in slight excess, which causes in the former "a purplish muddiness, and slowly a purplish precipitate," and in the latter, either no effect, or a dirty brownish precipitate.

Adulterations. The principal foreign substances which vinegar is liable to contain, are sulphuric acid and certain acrid substances, introduced by design, and copper and lead derived from improper vessels used in its manufacture. Muriatic and nitric acids are but rarely present. Chloride of barium will detect sulphuric acid, by producing a white precipitate in the diluted vinegar; whereas, if it be pure, the test will produce a slight yellowish, flocculent precipitate. Muriatic acid may be discovered by adding to a distilled portion of the suspected vinegar, a solution of nitrate of silver, which will throw down a curdy white precipitate. If nitric acid be present, it may be detected by saturating the vinegar with carbonate of potassa, and evaporating to obtain the saline matter. If nitrate of potassa be present in this, it will deflagrate partially on live coals, and give reddish vapours of nitrous acid, when mixed with brass filings, and treated with sulphuric acid. The acrid substances usually introduced into vinegar are red pepper, long pepper, pellitory, grains of paradise, and mustard seed. These may be detected by evaporating so as to form an extract, which will have an acrid, biting taste, if any one of the substances mentioned be present. By far the most dangerous impurities in vinegar are copper and lead. The former may be detected by a brownish precipitate on the addition of ferrocyanuret of potassium to the concentrated vinegar; the latter, by a blackish precipitate with sulphuretted hydrogen, and a yellow one with chromate of potassa. (*Chevallier, Amer. Journ. of Pharm.* ix. 33, *from the Journ. de Chim. Med.*) Pure vinegar is not discoloured by sulphuretted hydrogen.

Medical Properties. Vinegar acts as a refrigerant and diuretic. With this view, it is added to diluent drinks in inflammatory fevers. It is used in affections of the urinary organs, attended with a white deposit from the urine, which consists of phosphate of lime mixed with phosphate of magnesia and ammonia. It is sometimes used as a clyster, diluted with twice or thrice its bulk of water. It has been supposed to be a powerful antidote to the narcotic poisons, but this is a mistake. In the case of opium the best authorities unite in considering it worse than useless, as it rather gives activity to the poison than neutralizes it. Externally it is employed as a fomentation or lotion in bruises and sprains. Diluted with water, it forms the best means of clearing the eye from small particles of lime. Its vapour is inhaled in certain states of sorethroat, and is diffused through sick rooms under the impression that it neutralizes pestilential effluvia, though in fact it has no other effect than to cover unpleasant smells. The dose is from one to four fluidrachms; as a clyster from one to two fluidounces.

The basis of all the arsenical preparations is a peculiar metal called arsenic. It is brittle and of a steel-gray colour, and possesses much brilliancy when recently broken or sublimed. Exposed to the air, its surface becomes dull and blackens. Its texture is granular, and sometimes a little scaly. Rubbed in the hands it communicates a peculiar odour, but it is devoid of taste. Its sp. gr. is 5·7 according to Berzelius, 5·9 according to Guibourt. When heated to about 356° of Fahr. (*Berzelius*), it sublimes without fusing, giving rise to vapours having an alliaceous or garlicky odour. Its subliming point is differently given by Dr. J. K. Mitchell and Mr. Durand, who state it to be as high as a red heat visible in the dark. (*Journ. Phil. Col. of Pharm.* iv. 108. July 1832.) Its equivalent number is 37·7.

Arsenic forms two well characterized combinations with oxygen, both having acid properties, called *arsenious* and *arsenic acid*.

Preparation, &c. Arsenious acid is prepared chiefly in Bohemia and Saxony, where it is procured on a large scale, as a collateral product, during the smelting of cobalt ores, which are almost invariably accompanied by arsenic. These ores are roasted in reverberatory furnaces, with long horizontal flues. The arsenic is converted, by combustion, into arsenious acid, which sublimes and condenses on the sides of the flues. In this state it is not pure, and requires a second sublimation, which is performed in cast iron vessels, fitted with conical heads of the same material, having an opening at the summit. The vessels are placed over a furnace, and brought to a red heat, when a portion of the impure arsenious acid is thrown in through the opening, which is immediately stopped. This portion being sublimed, a new portion is introduced in a similar manner. Finally the vessels are allowed to cool, and the heads being removed, the purified acid is found attached to them in vitreous layers, at first as transparent as glass, but gradually becoming, by contact with the air, opaque at their surface. These are broken into fragments of a convenient size, and thrown into commerce. The arsenious acid which reaches this country is generally packed in casks, containing from two to five hundred pounds, and is shipped principally from the ports of Hamburg and Bremen.

Properties. Arsenious acid, as it occurs in commerce, is in masses exhibiting a vitreous fracture. It is of a milk-white colour exteriorly, but internally, perfectly transparent. As first sublimed, the whole mass is transparent, but it gradually becomes white and opaque, the change proceeding progressively from the surface inwards. The nature of this change has not been well determined. According to Guibourt, the sp. gr. of the transparent variety is 3·73; that of the opaque, 3·69. The experiments, however, of Dr. Mitchell and Mr. Durand make the density of the former variety from 3·208 to 3·333. As it occurs in the shops for medical use, it is often in the form of a white powder, almost as fine as flour. In this state it is some-

times adulterated with powdered chalk, or sulphate of lime, a fraud which is easily detected by exposing the powder to a heat sufficient to evaporate the arsenious acid, when these impurities will be left behind. To guard against the fraudulent impurities of the powdered acid, it is directed in the U. S. Pharmacopœia to be kept in masses. When pure it is completely dissolved by boiling water. It is erroneously stated to have an acrid taste. Dr. Christison asserts that it possesses hardly any taste, inasmuch as it produces merely a faint sweetish impression on the palate. In strong, hot solution, it has an austere taste, most nearly resembling that of sulphate of zinc. (*Mitchell and Durand.*) It has no smell even when in a state of vapour. The garlicky odour, which is sometimes attributed to it, belongs only to the vapour of the metal; and when apparently arising from the acid itself, is, in fact, owing to its reduction. Its point of sublimation, according to Berzelius, is at an incipient red heat; but, according to Mitchell and Durand, it is lower instead of higher than that of metallic arsenic, being only 425° of Fahr. When slowly sublimed, it condenses in regular octohedral crystals, exhibiting a sparkling lustre. It consists of two equivalents of arsenic 75.4, and three equivalents of oxygen $24=99.4$. It is, therefore, a sesquioxide in composition.

Arsenious acid is soluble in water. Guibourt states that its solubility differs according as it is transparent or opaque. Thus 1000 parts of water at 69° Fahr. dissolve 9.6 of the transparent, and 12.5 of the opaque variety; and the same quantity of boiling water dissolves 97 parts of the transparent, retaining 18 when cold, and 115 parts of the opaque, retaining 29 on cooling. These results show that a boiling saturated solution, when allowed to cool, retains more of the acid in solution, than can be dissolved in cold water without a preliminary boiling, and teach the propriety of employing a boiling temperature when searching for this mineral. The solubility of the powder of arsenious acid, as prepared for use in medicine, corresponds, of course, with that of the opaque variety. Guibourt, however, is said to be wrong as to the different solubility of the transparent and opaque varieties. From the experiments of Taylor it would appear, that the two forms do not differ in solubility, and that the quantity of the same variety which water will dissolve is very different according to the mode of effecting the solution; water in violent ebullition dissolving more than when moderately boiling, and the duration of the process having a decided influence on the result. (*Lond. and Ed. Phil. Mag. Nov. 1837.*)

Medical Properties. Internally, the action of the preparations of arsenic is alterative and febrifuge; externally, for the most part, violently irritant. They have been considered as peculiarly applicable to the treatment of diseases of a periodical character. When commencing their exhibition, the dose should be small, and afterwards gradually increased, the operation being carefully watched. When the specific effects of the medicine are produced, it must be immediately laid aside. These are, a general disposition to cedema, especially of the face and eyelids, a feeling of stiffness in these parts; itching of the skin, tenderness of the mouth, loss of appetite, and uneasiness and sickness of the stomach. The peculiar swelling produced is called *cedema arsenicalis*. Sometimes salivation is produced, and occasionally the hair and nails fall off. The principal preparations now in use are the arsenious acid, the substance under consideration, and the solution of arsenite of potassa, or Fowler's solution. The arseniates of potassa and soda, and the sulphuret of arsenic are also occasionally employed. One grain of the arseniate of soda, dissolved in a fluidounce of water, forms the *arsenical solution of Pearson*.

It may be questioned whether the different arsenical preparations act pre-

cisely in the same way, when exhibited internally. It is supposed by some that the selection need only be regulated by the convenience of exhibition. The late Dr. Physick, whose opinion is entitled to great respect, thought otherwise; for, with regard to the arsenious acid, and the solution of arsenite of potassa (Fowler's solution), the result of his experience was that they act differently, and cannot be substituted for each other. Cases of the efficacy of the metal, when given in the form of Fowler's solution, will be noticed under the head of *Liquor Potassæ Arsenitis*. For a complete list of the diseases in which arsenic has been tried, the reader is referred to Mr. Hill's paper in the *Edin. Med. Journal*, vols. v. and vi.

Some writers have entirely proscribed the use of the arsenical preparations in medicine. Amongst these, one of the most authoritative is Mr. Brande, who considers their introduction into the Pharmacopœias as a great evil, on account of the facilities afforded, by legalizing the medicinal use of the poison, for its employment for self-destruction and murder. At the same time he believes that more harm than benefit has resulted from its administration. (*Man. of Pharm.* p. 29.) We confess, however, that we do not share these opinions with Mr. Brande. Arsenic is a virulent poison, and is frequently employed for criminal purposes; but when it is considered how extensively it is used in the arts, it is questionable whether its exclusion from the *Materia Medica* would materially lessen the facility of obtaining it. On the other hand, it may be asked, are poisons more dangerous as medicines than other medicinal substances, if given in their appropriate doses? We should think not; though we admit that dangerous mistakes are more apt to occur. If the views of Mr. Brande were carried out, they would lead to the discarding of the corrosive chloride of mercury, hydrocyanic acid, strychnia, and other articles from the *Materia Medica*; but we believe that no practitioner will be found willing to strike these substances from the list of remedies.

While we wish to retain arsenic as a potent remedy in the hands of the judicious practitioner, we should be glad to find the sale of it subjected to strict regulations, under heavy penalties for their infraction.

Arsenious acid has been exhibited in a great variety of diseases, the principal of which are scirrhus and cancer, especially cancer of the lip; anomalous ulcers; intermittent fever; chronic rheumatism, particularly that form of it attended with pains in the bones; diseases of the bones, especially nodes, and firm swellings of the small joints of the hands; frontal neuralgia; and different painful affections of the head, known under the names of hemicrania and periodical headach. Mr. Henry Hunt of Dartmouth, England, found it useful in mitigating the pain of ulcerated cancer of the uterus and in menorrhagia; also in irritable uterus, attended with pain and bearing down in the erect posture. He gave it in pill, in the dose of a twentieth of a grain three times a day. In this dose the remedy seldom produces unpleasant feelings, and may be continued for three or four months, for which period it must sometimes be used, in order to produce the desired effect on the uterus. Arsenious acid has been extolled as a remedy in certain cutaneous affections, particularly lepra. Dr. Pereira says that he has seen it used in a large number of cases of this disease without a single failure to cure. Its external application has been principally restricted to cancer, and anomalous and malignant ulcers, especially of the kind denominated *noli me tangere*.

Arsenic is thought highly of by some practitioners in cases of lupus, and ill-looking sores of the face, lips, and tongue, and sometimes effects a cure. Dupuytren was in the habit of using with advantage a powder composed of

one part of arsenious acid and twenty-four parts of calomel, as a topical application to herpes exedens, and to the foul ulcers occurring in those who have undergone repeated courses of mercury.

Arsenic is the chief ingredient in nearly all the empirical remedies for the cure of cancer by external application. *Plunket's caustic* was a remedy of this kind, of great celebrity, and consisted of the *Ranunculus acris* and *Ranunculus Flammula*, each an ounce, bruised, and mixed with a drachm of arsenious acid, and five scruples of sulphur. The whole was beaten into a paste, formed into balls, and dried in the sun. When used, these balls are rubbed up with yolk of egg, and spread on pig's bladder. The use of the vegetable matter is to destroy the cuticle; for, unless this is done, the arsenic will not act. Mr. Samuel Cooper thinks this caustic was never of any permanent benefit in genuine cancer, but has effected perfect cures in some examples of lupus, and malignant ulcers of the lips and roots of the nails. In onychia maligna, Mr. Luke, of London, regards an ointment composed of two grains of arsenious acid and an ounce of spermaceti ointment as almost a specific. (*Pereira. Mat. Med.* 647.)

At Paris, an arsenical paste of the following composition is used as an application to malignant ulcers:—Red sulphuret of mercury 70 parts; dragon's blood 22 parts; arsenious acid 8 parts. It is applied, made up into a paste with saliva. The pain produced by this composition is very severe, and its application dangerous. The practice of sprinkling unmixed arsenious acid on ulcers is now reprobated, as fraught with the greatest danger. Mr. S. Cooper characterizes it as a murderous practice. It may, however, be used either in solution, or reduced by some mild ointment. A lotion may be formed of eight grains of arsenious acid and the same quantity of carbonate of potassa, dissolved in four fluidounces of distilled water; and a cerate, of one drachm of arsenious acid and twelve drachms of simple cerate. The cerate is sometimes formed of half this strength. The lotion is in effect a solution of arsenite of potassa.

Febure's remedy for cancer consisted of ten grains of arsenious acid dissolved in a pint of distilled water, to which were added an ounce of extractum conii, three fluidounces of liquor plumbi subacetatis, and a fluidrachm of tinct. opii. With this the cancer was washed every morning. Febure's formula for internal exhibition was, arsenious acid two grains, rhubarb half an ounce, syrup of chicory q. s., distilled water a pint. Of this mixture, a tablespoonful, which contained about a sixteenth of a grain of the acid, was given every night and morning, with half a fluidrachm of the syrup of poppies. The dose was gradually increased to six tablespoonfuls.

The average dose of arsenious acid is the tenth of a grain, three times a day, given in the form of pill. It is sometimes combined with opium, which enables the stomach to bear the mineral better. A convenient formula is to mix one grain of the acid with ten grains of sugar, and to beat the mixture thoroughly with crum of bread, so as to form a pilular mass, to be divided into ten pills. The *Asiatic pills*, so called, consist of arsenious acid and black pepper, in the proportion of 1 part of the former to 80 of the latter.

Properties of Arsenious Acid as a Poison. Arsenious acid, in an overdose, administered internally, or applied externally, acts with very great energy, and generally destroys life in a short time. The symptoms it produces are an austere taste; fetid state of the mouth; frequent pytalism; continual hawking; constriction of the pharynx and œsophagus; the sensation of the teeth being on edge; hiccups; nausea; anxiety; frequent sinkings; burning pain at the precordia; inflammation of the lips, tongue, palate, throat, and œsophagus; irritable stomach, so as not to be able to support

the blandest drinks; vomiting of matters, sometimes brown, at other times bloody; black, horribly fetid stools; small, frequent, concentrated, and irregular pulse, but occasionally slow and unequal; palpitations; syncope; insatiable thirst; burning heat over the whole body, or a sensation of icy coldness; difficult respiration; cold sweats; scanty, red, and bloody urine; change in the countenance; a livid circle round the eye-lids; swelling and itching of the body; livid spots over the surface, and occasionally a miliary eruption; prostration of strength; loss of feeling, especially in the feet and hands; delirium; convulsions, often accompanied with insupportable priapism; falling off of the hair; detachment of the cuticle, &c. Sometimes there exist inflammation and burning pain in the urino-genital organs. It is very rare to observe all these symptoms in the same individual. In some cases, indeed, they are nearly all wanting, death taking place without any pain or prominent symptoms. After death, the morbid appearances are various. In some cases, no vestige of lesion can be discovered. The appearances, however, in the generality of cases, are the following. The mouth, stomach, and intestines are inflamed; the stomach and duodenum exhibit spots resembling eschars, and perforations of all their coats; and the villous coat of the former is in a manner destroyed, and reduced to the consistence of a reddish-brown pulp.

Dr. Christison divides the poisonous effects of arsenious acid into three orders of cases, according to the character and violence of the symptoms. In the first order, the poison produces symptoms of irritation and inflammation along the course of the alimentary canal, and commonly kills in from one to three days. In the second, the signs of inflammation are moderate, or even altogether wanting, and death occurs in five or six hours, at a period too early for inflammation to be always fully developed. In the third order of cases, two stages occur, one in which inflammatory symptoms are developed, as in the first order; the other, marked by symptoms referable to nervous irritation, such as imperfect palsy of the arms or legs, epilepsy, tetanus, hysterical affections, mania, and coma. It is a general character of this poison to induce inflammation of the stomach in almost all instances, provided death does not take place immediately, whatever be the part to which it is applied. Thus the poison, when applied to a fresh wound, will give rise to the same morbid appearances in the stomach and intestines, as when it is swallowed. In some cases, observed by Drs. Mall and Bailie, the rectum was much inflamed, while the colon and small intestines escaped.

The precise rank which should be assigned, in the scale of poisons, to arsenious acid when applied externally, is still undetermined. One set of observers contend that its external application is not attended with great danger; while another party conceives that it acts as a virulent poison. Hunter, Sir Everard Home, Jøger, Brodie, Dr. Campbell of Edinburgh, Smith, and Orfila, have all adduced experiments on the inferior animals, which prove that arsenious acid, inserted into a recent wound, causes death after a longer or shorter period. Indeed, some observations go to prove that the poisonous effects of the substance are developed in a smaller dose, when used in this way, than when taken into the stomach. Nor are there wanting many well authenticated facts of its deleterious effects on the human constitution. Roux reports the case of a young woman under his care, whose death was caused, after agonizing sufferings, by the application of an arsenical paste to a cancerous breast. A case is related of death from the application of an arsenical paste to a soft tumour of the temple; the poisonous effects on the system at large being the cause of the fatal result. (*Archives Générales*, ii. 230.) Sir Astley Cooper, in his lectures, bears testimony to

the dangerous effects of arsenic externally applied. On the other hand, some writers contend for the safety of the external application of this poison. Mr. Blackadder applied it in large quantities to sores, and never witnessed a single instance in which it acted constitutionally. Dr. Randolph, of this city, (*North Amer. Med. and Surg. Journ.* v. 257), states that Dr. Physick frequently and successfully employed arsenic by external application, without its being productive of the injurious consequences which have been attributed to it. In weighing such conflicting testimony, we are constrained to believe, that the circumstances of the different experiments and observations must have been different; and we think that the observations of Blackadder and Harles show in what this difference consists. It seems to depend entirely on the circumstances of the application, as being favourable or unfavourable to absorption. Blackadder attributes his very success to the large quantities of the arsenic which he employs; and which, he contends, kills the part without being absorbed; and this is probably the fact. Harles's observations may be explained on the same principle. He contended that the outward application of arsenic is comparatively safe to ulcers, either common or malignant; but is dangerous to parts recently wounded and pouring out blood. Here the difference would seem to consist in the greater liability to absorption in the latter than in the former case. The very dilution caused by the blood, may be an efficient promoter of absorption, and is entirely consonant with the experiments of Dr. Campbell, who found that arsenic acted with more energy, when dissolved in water, than in the solid state. The case in which Dr. Randolph employed this mineral, by the advice of Dr. Physick, was one of ulcerated scrotum, in which it acted by producing the death of the diseased part, a state evidently unfavourable to absorption. The formula employed was one part of the arsenious acid to five of the flowers of sulphur.

Arsenious acid, when it produces the death of a part, does not act, strictly speaking, as an escharotic. It destroys the vitality of the organized structure, and its decomposition is the consequence. The true escharotic acts chemically by decomposing the part to which it is applied, and the loss of life follows. This distinction being borne in mind, we can explain why the operation of arsenious acid is often limited to the destruction of diseased formations, which are known to possess a feeble vitality; while the true escharotics destroy both the diseased and healthy structure. When the arsenious acid succeeds as an external application to cancers, which is a very rare occurrence, it acts on this principle; destroying the vitality of the whole diseased portion, and causing it to be thrown off as something foreign to the system.

Upon the whole, new facts are wanting to clear up this difficult subject. Judging from the lights we possess, the external application of arsenious acid, in case it is absorbed, is attended with very great danger; and the conditions of a part and of the system at large, favourable or otherwise to absorption, are too little understood, to make it warrantable to use this poison externally without the greatest caution.

Treatment of Poisoning by Arsenious Acid. Before the antidote, to be mentioned presently, can be obtained, the poison should be dislodged as far as possible by free vomiting, induced by the finger, the feather part of a quill, and the administration of an emetic of sulphate of copper or sulphate of zinc. The same object is promoted by the use of the stomach-pump. Demulcent drinks should at the same time be freely given, such as milk, white of eggs and water, or flour and water, which serve to encourage the vomiting and envelope the poison.

The antidote above referred to is the hydrated sesquioxide (peroxide) of iron in the *moist* or *pulpy* state. As soon as it is ready, it must be given in doses of a tablespoonful to an adult, of a dessertspoonful to children, every five or ten minutes, until the urgent symptoms are relieved. It is calculated that the quantity taken should be at least twelve times the supposed amount of the poison swallowed; but as the antidote is perfectly innocent, it is prudent to give it in larger quantities. Its efficacy is of course greater, the sooner it is administered after the ingestion of the poison; but even after delay, its use will prove advantageous, so long as there is reason to believe that a portion of the poison still remains in the stomach. The antidote acts by producing with the poison, by a transfer of oxygen from the oxide to the acid, an insoluble and therefore inert subarsenate of protoxide of iron ($4\text{FeO} + \text{As}_2\text{O}_5$). The manner of preparing the antidote will be given under another head. (See *Ferri Oxidum Hydratum*, U. S.) It should be kept by all apothecaries ready for use.

This antidote for arsenious acid was discovered by Drs. Bunsen and Berthold, of Göttingen, in 1834, and its efficacy has been abundantly confirmed by experiments on inferior animals, and by its successful application to numerous cases of poisoning in the human subject. Among others, the reader is referred to the following:—1. The case of M. Blondel, in which two drachms of arsenic had been swallowed, (*Amer. Journ. of Pharm. new series*, i. 350, from the *Journ. de Chim. Méd.*) 2. Two cases treated by Dr. Buzorini, (*French Lancet*, Nov. 17, 1835.) 3. A case reported by Mr. John Robson, in which more than a drachm and a half of the poison had been swallowed, and the antidote was not administered until two hours after the poison had been taken. In the last mentioned case, about an hour after the ingestion of the poison, the stomach-pump had been used, but unsuccessfully, on account of the instrument becoming choked with the remains of food. (*Amer. Journ. of the Med. Sci.* xx. 222, from the *Lond. Med. Gazette of Nov. 5, 1836.*) 4. Case related by Dr. Thomas, of Baltimore, in which twenty grains of the poison had been swallowed. (*Amer. Med. Library and Intelligencer*, ii. 205.) 5. Case of Dr. Macdonald in the *New York Journ. of Medicine and Surgery*, ii. 205. 6. Case reported by Dr. Gerhard, (*Med. Exam.* iii. 250.) 7. Cases related by Drs. Smiley and Wallace of this city. A family of eight persons were poisoned, of whom six recovered and two died. In the fatal cases, the patients could not retain the antidote. (*Med. Exam.* iii. 679.)

Since the publication of the last edition of this Dispensatory, several valuable observations have been made as to the antidotal powers of the different oxides of iron, and the circumstances which influence their efficacy. The forms of oxide experimented with, are the anhydrous sesquioxide (colcothar), the dry hydrated sesquioxide (rust of iron and the subcarbonate of iron of the U. S. Pharmacopœia, which are both essentially hydrated oxides), the hydrated oxide in the state of pulp or magma, and the same oxide kept under a stratum of water. Orfila has shown that *colcothar* is without effect, because it does not combine with the arsenious acid. Dr. Von Specz, of Vienna, has proved that *rust of iron* acts as an antidote to arsenious acid, but, being much less powerful than the pulpy hydrate, should be used only in the absence of the latter, and until it can be procured. Orfila agrees with Von Specz as to the degree of efficacy of the rust, and explains its inferior power by its inability *completely* to neutralize the arsenious acid. According to the French toxicologist, it forms with the acid a subsalt which is poisonous, though in a much inferior degree to the free arsenious acid. Thus it would appear that Dr. T. R. Beck is in error in stating

that the dry hydrated oxide is inert. (*Amer. Journ. of the Med. Sciences, new series*, ii. 95.) All the best authorities unite in considering the *hydrated oxide* in the state of *pulp* or *magma* to be the best form of the antidote; but opinions are divided as to the necessity of its being *freshly* prepared as well as moist, and as to the relative advantage of much or little water, to maintain it in the moist state. An able paper, recently published by Mr. William Proctor, Jr., of this city, (*Amer. Journ. of Pharmacy*, xiv. 29, April, 1842,) appears to have settled these disputed points. He has proved by satisfactory experiments, that the moist oxide gradually decreases in its power of neutralizing arsenious acid the longer it is kept, and that this decrease in power is more rapid in the oxide, when mixed with much water, than when in the form of a thick magma.

It follows from the above facts and observations, that the forms of sesquioxide of iron are efficacious as antidotes to arsenic in the following order, beginning with the one having least power:—1, dry hydrated oxide; 2, hydrated oxide, long kept and mixed with much water; 3, the same long kept, and in the form of a thick magma; 4, the same just precipitated and still pulpy. The form of antidote which can be obtained first must be used first, although not the best, and may be replaced by a better as soon as it can be procured. The apothecary should, therefore, always keep the oxide in the form of thick magma, and, as Mr. Proctor suggests, be prepared, at a moment's warning, to make the antidote. When applied to for it, he must instantly furnish the magma, or, if unprovided with this, the rust or precipitated carbonate, and immediately proceed to prepare the oxide which may be done, according to Mr. Proctor, in ten or fifteen minutes, if the proper solutions are always ready for effecting the precipitation.

The solutions necessary are those of the sulphate of sesquioxide of iron, and of ammonia. The preparation of this sulphate in solution forms the first step in the official formula for obtaining the antidote, and will be explained under the head of that substance. (See *Ferri Oxidum Hydratum*.)

The antidote having been faithfully applied, the subsequent treatment consists in the administration of mucilaginous drinks. Should the patient survive long enough for inflammatory symptoms to arise, these should be combated on the general principles of treating inflammation. Accordingly, venesection and leeches may become necessary; and in the course of the treatment, emollient enemata, antispasmodics, and narcotics will often prove useful in mitigating pain and allaying nervous irritation. Convalescence is generally long and distressing, and hence it becomes of the greatest importance to attend to the diet, which should consist exclusively of milk, gruel, cream, rice, and similar bland articles.

It was formerly supposed that bodies poisoned by arsenious acid were unusually prone to putrefaction; but so far from this being the case, it exerts a preservative effect.

Reagents for detecting Arsenious Acid. As arsenic is so frequently employed for criminal purposes, it becomes of importance to detect its presence in medico-legal investigations. The tests for it may be divided into, 1. those which indicate indirectly its presence; and, 2. those which demonstrate its presence incontestably, by bringing it to the metallic state. The former embrace all the liquid reagents, so called; the latter the different processes for metallization.

The most characteristic reagents, according to Dr. Christison, are *sulphuretted hydrogen*, *ammoniacal nitrate of silver*, and *ammoniacal nitrate of copper*. In the opinion of this writer, the concurrent indications of these three tests are all-sufficient for detecting, in an infallible manner, the presence

of arsenious acid; but we think that in questions involving life and death, it is best to make assurance doubly sure, and, therefore, that the metallization of the poison ought never to be omitted.

In using sulphuretted hydrogen, the solution must be neutral. An excess of alkali may be neutralized with acetic acid; and an excess of nitric or sulphuric acid, by potassa. A slight excess of acetic acid is not, however, hurtful; on the contrary, it rather favours the subsidence of the precipitate, which is of course sulphuret of arsenic. According to Dr. Christison, this test is so exceedingly delicate, that it detects the poison, when dissolved in one hundred thousand parts of water. The colour it produces is lemon or sulphur-yellow; but the presence of vegetable or animal matter commonly changes it to a whitish or brownish tint. Some medical jurists recommend the use of sulphuretted hydrogen water; but the gas is far preferable. It can be applied with much convenience by using one of Dr. Hare's self-regulating gas reservoirs.

Dr. Christison has shown, that how delicate soever the ammoniacal nitrate of silver may be in ordinary solutions, it is not to be depended upon in dilute solutions of the poison, where animal or vegetable matter is present; for the precipitate is either not formed in consequence of the organic principles exerting a solvent power over it, or, if formed, is essentially altered in colour.

The ammoniacal sulphate of copper is a test of very great delicacy. The precipitate occasioned by it is the arsenite of copper, of an apple-green or grass-green colour. Its operation is prevented by muriatic, nitric, sulphuric, acetic, citric, and tartaric acids in excess; as also by ammonia. But a greater objection to it is, that its indications fail when animal or vegetable matter is present, in case the arsenic is not abundant.

Of the three tests mentioned, perhaps the sulphuretted hydrogen is the most delicate; and it has the advantage of yielding a precipitate eligible for subsequent reduction. But they are all liable to the objection of being obscured in their indications, where the amount of poison is minute, by the presence of organic principles; a complication which constitutes the most difficult problem which can be presented to the attention of the medical jurist. As this case includes all others of more easy solution, we shall suppose it presented to the medical chemist, and shall indicate the steps which are to be pursued.

Having obtained general indications of the presence of arsenic, the first step will be to separate the organic matters; the second, to throw down the arsenic by means of sulphuretted hydrogen; and the third, to reduce the precipitate obtained.

The following are the directions given by Dr. Christison for separating the organic principles. Boil the suspected matter with distilled water for half an hour, and filter, first through gauze to separate the coarser particles, and afterwards through paper. To the transparent solution thus obtained, add acetic acid, which will coagulate some animal principles. To ascertain whether the solution has been sufficiently freed from animal matter by this measure, neutralize with ammonia, and test a small portion of it with the ammoniacal nitrate of silver. If this gives a characteristic precipitate, the solution is sufficiently deprived of animal matter; if not, another measure must be adopted to separate it. This consists in first rendering the solution neutral or slightly alkaline, next faintly acidulating with muriatic acid, and then adding an excess of nitrate of silver. This salt precipitates the animal matter in combination with oxide of silver. After this step, the excess of

silver is thrown down by a slight excess of chloride of sodium (common salt), and the solution filtered.

Having in this manner disembarassed the solution of organic matter, the free nitric acid is neutralized by potassa in slight excess, and the solution acidulated with acetic acid. A stream of sulphuretted hydrogen is then passed through it, which will throw down the arsenic as sesquisulphuret. If the proportion of arsenic be very small, a yellowishness only will be produced, owing to the precipitate being soluble in an excess of the precipitant. In this case it is necessary to boil, to drive off the excess of sulphuretted hydrogen. The precipitate is then collected and dried. If it be very minute, it must be allowed to subside, and the clear liquid having been withdrawn, the remainder is to be poured upon a filter. After filtration, the precipitate is washed down to the bottom of the filter by means of the instrument called the *pipette*, employed for washing scanty precipitates. The filter is then gently pressed between folds of bibulous paper, and the precipitate removed with the point of a knife before it dries, and then dried in little masses on a watch-glass. In this manner Dr. Christison states that it is easy to collect a portion of the sesquisulphuret so small as the twenty-fifth part of a grain. When the precipitate is small and not easily separated, Devergie recommends to dissolve it in a small quantity of ammonia, and then filter and evaporate the solution in a watch-glass, when the sesquisulphuret will be left. The precipitate is then to be reduced by means of a flux, which this author recommends to consist of two parts of ignited carbonate of soda and one of charcoal, as preferable to black flux. The best flux for the arsenious acid is freshly ignited charcoal.

A method different from that of Dr. Christison has been recommended by M. Maufflier for separating organic substances. It consists in adding to the liquid, resulting from the decoction of the suspected matters, a solution of oxide of zinc in potassa. The oxide precipitates in union with the organic substances, while the potassa unites with the arsenious acid and remains in solution. The clear solution, obtained by decantation or filtration, being then acidulated with muriatic acid, the arsenic is precipitated by sulphuretted hydrogen, as recommended by Dr. Christison. (*Journ. de Pharm.* xx. 492.)

The general formula for reduction is as follows. The operation is performed in a small glass tube. If the matter to be operated on is small, it is introduced to the bottom of the tube, and then a little of the flux is added to cover it, care being taken that the materials are conducted to the place they are to occupy, by means of a small glass funnel with a slender stem, without soiling the empty part of the tube. The heat is to be applied by means of a spirit lamp, the upper part of the material being first heated with a small flame, and afterwards the lower part with a larger flame. A little water, disengaged at first, should be removed with a roll of filtering paper, before sufficient heat has been applied to sublime the metal. When the dark crust begins to form, the tube should be held quite steady, and in the same part of the flame. This crust is the metallic arsenic, having the surface next the tube resplendent and polished, and the interior surface crystallized. Its characters are quite distinct, even when it does not amount to more than the three-hundredth part of a grain. If any doubt should be felt as to the nature of the crust, it may be driven up and down the tube, so as to convert it into sparkling octohedral crystals of arsenious acid, readily seen with a magnifying glass. Finally, the crystals may be dissolved in a drop or two of distilled water, and the solution will react characteristically with the liquid tests.

A new method of testing for arsenic has been proposed by Mr. Marsh.

(*Edin. New Phil. Journ. for Oct. 1836.*) It consists in taking advantage of the power, which nascent hydrogen possesses, of decomposing the acids of arsenic, with the result of forming water and arseniuretted hydrogen. The liquid in the stomach, or obtained from its contents by boiling water, is mixed with some dilute sulphuric acid, and placed in a self-regulating reservoir for hydrogen, in which a piece of zinc is suspended. The materials are here present for the production of hydrogen; but if the liquid from the stomach contain arsenic, the nascent hydrogen will combine with the metal, and the nature of the compound gas formed may be ascertained by burning a jet of it from a fine jet-pipe connected with the reservoir, taking care that the atmospheric air is first expelled before applying the fire, for fear of an explosion. The flame will have a characteristic blue colour, and by holding a piece of white porcelain over it, a thin film of metallic arsenic will be formed. Liebig and Mohr bear testimony to the delicacy of this test; but to remove every source of fallacy, it is necessary to be sure of the purity of the apparatus, as well as of the zinc and sulphuric acid; as these latter are liable to contain a minute portion of arsenic. The piece of zinc employed should be changed in every experiment.

Lassaigne has proposed to pass the arseniuretted hydrogen through a solution of nitrate of oxide of silver. Arsenious acid is formed, nitric acid set free, and metallic silver deposited in black flocculi. Muriatic acid is cautiously added to the decanted liquid to decompose the excess of the nitrate, by throwing down its silver in the form of a chloride. The filtered liquor will contain nitric and arsenious acids, the latter of which may be detected by the usual tests. Or it may be evaporated to dryness, whereby the arsenious becomes arsenic acid, by oxygen derived from the nitric acid which is decomposed. The solution of arsenic acid obtained from the dry residuum is then tested by nitrate of silver which forms with it a brick-red precipitate of arseniate of silver. Lassaigne's mode of proceeding has the merit of saving the first portions of the arsenical gas.

Marsh's test has been objected to by Mr. L. Thompson, who alleges that antimony forms a compound with hydrogen, very similar to arseniuretted hydrogen, both in the colour of its flame, and in the metallic crust which it deposits during combustion on cold surfaces. Still, according to Turner, these two compounds of hydrogen may be discriminated. For further details, see Turner's Chemistry, Sixth American Edition, p. 335, where a figure of the apparatus to be employed is given.

ACIDUM CITRICUM, *U. S., Lond., Ed., Dub.*

Citric Acid.

Acidum limonis; Acide citrique, Fr.; Citronensäure, Germ.; Acido citrico, Ital., Span.

Citric acid is the peculiar acid to which limes and lemons owe their sourness, being found in greatest abundance in the former. It is present also in the juice of other fruits, though in smaller amount; such as the cranberry, the red whortleberry, the berry of the bittersweet, the red gooseberry, the currant, the strawberry, the raspberry, and the tamarind.

The acid is extracted from lemon or lime juice by a very simple process, for which we are indebted to Scheele. The juice is imported into the United States from the West Indies, principally from the Island of Cuba, for the purpose of being converted into syrup, or manufactured into citric

acid. To obtain the acid, the juice is first completely saturated with carbonate of lime, (chalk or whiting,) in fine powder, and the citrate of lime formed is allowed to subside. This is then washed repeatedly with water, and decomposed by diluted sulphuric acid. An insoluble sulphate of lime is immediately formed, and the citric acid, being separated, remains in the supernatant liquor. This is carefully concentrated in leaden boilers, until a pellicle begins to form, when it is transferred to other vessels in order to cool and crystallize. As the crystals obtained by the first crystallization are generally brown, they require to be redissolved and recrystallized for several successive times, in order to render them pure and white.

The late Mr. Parkes, in his *Chemical Essays*, has given a very interesting account of the manufacture of citric acid, which is made in large quantities in London for the use of the calico-printers. As Mr. P. was himself engaged in this manufacture, the following outline of the process which he pursued, may be received with the greater confidence. The juice is placed in large square vats, in which it is saturated with clean soft chalk or whiting, gradually added to prevent excessive effervescence. The insoluble citrate of lime is allowed to subside, and the supernatant liquid, containing mucilage, saccharine matter, and a little malic acid, is drawn off by means of a siphon. The citrate is then passed through a sieve, and washed with warm water, until all remaining mucilage, and other soluble impurities are removed. It is then decomposed, while yet moist, by means of sulphuric acid, taken in the proportion of nine pounds and a half of the strong acid diluted with seven gallons of water, for every ten pounds of chalk used in the saturation. Some deduction, however, may be made from the water of dilution, in consideration of the water present in the moist citrate. The quantity of chalk expended may be easily ascertained by weighing out more than is sufficient for the purpose of saturation, and weighing the remainder after the point of saturation shall have been attained. The sulphuric acid is gradually poured in immediately after the water has been added to it, in order that the decomposition may be assisted by the heat generated by its dilution; and at the same time, the whole is well stirred with a strong wooden spatula, in order to prevent the citrate from running into lumps and thus escaping the action of the acid. As the point of complete decomposition of the citrate approaches, the sulphate of lime precipitates more and more quickly, and the quantity of supernatant liquid becomes sensibly greater. When the decomposition has been completed, the solution of citric acid is drawn off, and the sulphate of lime washed repeatedly with *cold* water, to separate any remains of acid. The solution of the acid, together with the washings, is then concentrated by evaporation in leaden boilers, until it reaches the sp. gr. of about 1.130; when the fire is withdrawn and the acid removed to a smaller leaden vessel, where it undergoes a further concentration by means of a water-bath. When the bulk of the acid liquor becomes very much reduced by evaporation, it requires to be transferred to a still smaller leaden boiler, where it is further evaporated by the same means, until the liquor acquires the consistence of very thin molasses. It is then watched with the greatest attention for noting the production of a pellicle, upon the appearance of which over the whole surface of the liquor, the acid is to be deemed sufficiently concentrated, and must be immediately removed from the water-bath, and put aside to cool and crystallize. If at this stage of the process the removal of the acid were neglected, the whole would be in danger of being charred and spoiled.

The liquor is allowed to remain at rest four days, that crystals may be formed, from which the mother waters, presenting a black colour, are to be

drained. These are then diluted with ten or twelve times their bulk of water, saturated anew by means of carbonate of lime, and treated in all respects as if they consisted of fresh lemon juice. By this proceeding, a new crop of crystals will be obtained.

Whatever care may be taken in conducting the process, the first crop of crystals will be of a light brownish colour; but if the solution has been burnt during the evaporation, or the mucilage imperfectly separated, they will be dark brown or black. In order to have the crystals perfectly pure and white, it is necessary to subject them to repeated solutions and crystallizations. According to Mr. Parkes, a gallon of good juice, if the process be well conducted, will yield eight ounces of white crystals. But the product depends very much on the proportion of citric acid in the juice, which is very variable. The more recent the juice the better the quality. That which is stale will sometimes be quite sour, without containing any citric acid, in consequence of its having undergone the acetous fermentation.

In decomposing the citrate of lime by sulphuric acid, it is not prudent to trust altogether to the appearance of the liquor, in deciding when the decomposition is complete. A more certain criterion is to filter a small portion of the liquor, and test it with acetate of lead. If no sulphuric acid be present in excess, the precipitate will consist of citrate of lead, and be entirely soluble in nitric acid. On the contrary supposition, the precipitate will be a mixture of citrate and sulphate of lead, the latter of which will remain undissolved on the addition of nitric acid.

It is desirable to have a slight excess of sulphuric acid; as it rather favours than otherwise the crystallization of the citric acid. It is found necessary also, to add occasionally a small portion of sulphuric acid to the citric acid liquor, during the progress of its concentration.

Citric acid is manufactured in different cities of the United States, for use in the arts and in medicine. In Philadelphia it is made in the usual manner, from the juice of limes and lemons. The imported juice furnishes from four to six ounces of the pure crystallized acid to the gallon.

Citric acid is properly placed in the *Materia Medica* of the United States Pharmacopœia, as an article purchased from the manufacturing chemist, and not made by the apothecary. The British Colleges place it among the preparations.

The following is an outline of the process of the London Pharmacopœia of 1836, for preparing this acid. Four ounces and a half of prepared chalk are added by degrees to eighty fluidounces of heated lemon juice. The resulting citrate of lime is carefully washed with tepid water, and decomposed, while yet moist, by the addition of twenty-seven and a half fluidounces of diluted sulphuric acid, and forty fluidounces of distilled water. The liquor is boiled for a quarter of an hour, and, after having been strained through a cloth with strong compression, is filtered. The filtered liquor is then evaporated by a gentle heat, and set aside to crystallize. The solution and crystallization are to be repeated several times, in order to get the crystals pure.

The process of the Edinburgh Pharmacopœia, which is now for the first time introduced, is substantially the same with the London. The principal differences are, that the Edinburgh College purifies the lemon juice to a certain extent from mucilage by boiling, rest, and subsidence, before it is boiled with a view to the addition of the chalk, and indicates the proportion of the diluted sulphuric acid to the chalk expended, without fixing the absolute quantities. These are improvements; for the presence of much mucilage interferes with the purification of the crystals, and the quality of the juice

is too variable to allow of the quantity of chalk necessary for saturation to be fixed. Dr. Christison states that the juice is advantageously clarified by albumen.

In the process of the Dublin College, the citrate of lime, which is unnecessarily directed to be dried, is decomposed by a quantity of diluted sulphuric acid, equal to eight times the weight of the chalk employed.

Properties. Citric acid is a white crystallized solid, often in large crystals, having the form of rhomboidal prisms with dihedral summits. It is permanent in a dry air, but becomes moist in a damp one. Its sp. gr. is 1.6. Its taste is strongly acid, and almost caustic. When heated, it dissolves in its water of crystallization, and at a higher temperature undergoes decomposition, becoming yellow or brown, and forming a very sour syrupy liquid, which is uncrystallizable. By destructive distillation, it gives rise to water, empyreumatic oil, acetic and carbonic acids, carburetted hydrogen, and a number of pyrogenous acids; and a voluminous coal is left.

Citric acid dissolves in three-fourths of its weight of cold, and half its weight of boiling water. It is also soluble in alcohol. A weak solution of it has an agreeable taste, but cannot be kept, as it undergoes spontaneous decomposition. It is incompatible with alkaline solutions, whether pure or carbonated, converting them into citrates; also with the earthy and metallic carbonates, most acetates, the alkaline sulphurets, and soaps. It is characterized by its taste, by the shape of its crystals, and by its forming an insoluble salt with lime, and a deliquescent one with potassa. If sulphuric acid be present, the precipitate by acetate of lead will not be entirely soluble in nitric acid; the insoluble portion being sulphate of lead. Sometimes large crystals of tartaric acid are substituted for or mixed with the citric, a fraud which is readily detected by the addition of carbonate of potassa, which forms with the substituted acid a crystalline precipitate of bitartrate of potassa (cream of tartar). Lime or other fixed impurity is detected by incinerating the acid, either alone or by the aid of red oxide of mercury, when the fixed matter will be left.

Composition. This acid consists of two eqs. of hydrogen 2, four of carbon 24.48, and four of oxygen 32=58.48. The acid usually met with in commerce contains one and a third equivalents of water.

Medical Properties. Citric acid is principally employed for making a substitute for lemonade, and in the composition of effervescing draughts. It is used also for preparing the neutral mixture, for which a formula has been newly introduced into the U. S. Pharmacopœia. (See *Liquor Potassæ Citratis*, U. S.) When added in the quantity of nine drachms and a half to a pint of distilled water, it forms a solution of the average strength of lime juice. Of this solution, or of lemon juice, a scruple of bicarbonate of potassa saturates three fluidrachms and a half; a scruple of carbonate of potassa, four fluidrachms; and a scruple of carbonate of ammonia, six fluidrachms. Half a fluidounce of lemon juice, or of an equivalent solution of citric acid, when saturated, is considered a dose. An agreeable substitute for lemonade may be formed by dissolving from two to four parts of the acid, mixed with a little sugar and oil of lemons, in nine hundred parts of water; or a scruple of the acid may be dissolved in a pint of water, and sweetened to the taste with sugar which has been rubbed on fresh lemon-peel.

ACIDUM MURIATICUM. U.S., *Dub.**Muriatic Acid.*

“Aqueous solution of chlorohydric acid gas of the specific gravity 1.16.” *U. S.*

Off. Syn. ACIDUM HYDROCHLORICUM. *Lond.* ACIDUM MURIATICUM PURUM. *Hydrochloric acid.* ACIDUM MURIATICUM. *Hydrochloric acid of commerce.* *Ed.*

Spirit of sea-salt, Marine acid, Hydrochloric acid, Chlorohydric acid; Acide hydrochlorique, *Fr.*; Salzsäure, Kochsalzsäure, *Germ.*; Acido muriatico, *Ital.*, *Span.*

The muriatic acid of pharmacy and the arts, is a solution of muriatic acid gas in water. It is sometimes called *liquid* muriatic acid, but more properly *aqueous* muriatic acid. The acid is officinal in its pure form in the U. S., London, and Dublin Pharmacopœias, and in its pure and commercial forms in the Edinburgh. The sp. gr. of the pure acid is directed to be 1.16 in the U. S., London, and Dublin Pharmacopœias, and 1.17 in the Edinburgh. The three British Colleges give a process for the preparation of the pure acid; while, in the United States Pharmacopœia, it is placed exclusively in the list of the Materia Medica, as an article to be procured from the manufacturing chemist.

Preparation. Muriatic acid is obtained by the action of sulphuric acid on chloride of sodium or common salt. The commercial acid is procured, on a large scale, by distilling the salt with an equal weight of sulphuric acid, somewhat diluted with water, from iron stills furnished with earthen heads, into earthenware receivers containing water. Thus obtained, it is contaminated with iron and other impurities, and is not fit for medicinal purposes.

Commercial muriatic acid is now obtained in large quantities in England, during the decomposition of common salt, for the purpose of making sulphate of soda, out of which soda-ash and carbonate of soda are manufactured in immense quantities. Indeed the quantity of acid generated in soda works is so great, that in many cases, so far from its being valuable, it is a difficult problem to devise means to get rid of it. When the object is to obtain sulphate of soda, the decomposition of the sea salt is performed in semi-cylindrical vessels, the curved part, next the fire, being made of iron, and the upper or flat surface, of stone. If the acid is saved, it is conveyed by a pipe to a double-necked stoneware receiver, half filled with water, and connected with a row of similar receivers, likewise containing water.

The acid is generally prepared in the laboratory, when required to be pure, by saturating distilled water with the gas in a Woulfe's apparatus. A quantity of pure fused* common salt is introduced into a retort or matrass, placed in a sand-bath. The vessel is then furnished with an S tube, and connected with the series of bottles, each two-thirds full of water. A quantity of sulphuric acid is then gradually added, equal in weight to the common salt employed, and diluted with one-third of its weight of water. The materials ought not to occupy more than half the body of the retort. When the extrication of the gas slackens, heat is to be applied, and gradually increased until the water in the bottles refuses to absorb any more, or until, upon raising the heat, no more gas is found to come over. As soon as the process is completed, boiling water is to be added to the contents of the retort, in order to facilitate the removal of the residue. During the progress

* According to Thenard, the fusion of the common salt will very much facilitate the conducting of the process.

of the saturation, the water in the several bottles increases in temperature, which lessens its power of absorption. It is therefore expedient, in order to obtain a strong acid, to keep the bottles cool by means of water or ice. The connecting tubes need not plunge deeply into the acid.

The rationale of the process for obtaining this acid is sufficiently simple. Common salt is a compound of chlorine and sodium; muriatic acid, of chlorine and hydrogen; and liquid sulphuric acid, of dry sulphuric acid and water. The water is decomposed; its oxygen, combining with the sodium of the common salt, generates soda, which unites with the sulphuric acid to form sulphate of soda; while the hydrogen and chlorine, being both in the nascent state, combine and escape as muriatic acid gas. The residue of the process is consequently sulphate of soda, or Glauber's salt. It is reserved by the British Colleges to be dissolved and crystallized, in order to form the officinal sulphate of soda. (See *Sodæ Sulphas*.)

The following is a synopsis of the proportions of the ingredients prescribed by the British Colleges for obtaining the pure acid:—*London*, two pounds of dried chloride of sodium, twenty ounces of sulphuric acid, and twenty-four fluidounces of distilled water;—*Edinburgh*, equal weights of purified and well dried salt, pure acid, and water;—*Dublin*, one hundred parts of dried salt, eighty-seven of commercial sulphuric acid, and one hundred and twenty-four of water. The Edinburgh College distils “with a gentle heat by means of a sand-bath or naked gas-flame, so long as any liquid passes over, preserving the receiver constantly cool by snow or a stream of cold water.” The Dublin College distils the materials to dryness. One-third of the water prescribed in the Edinburgh formula, and one-half of that directed in the London and the Dublin, is mixed with the sulphuric acid; the rest being put into the receiver to absorb the gas.

From the above view, it is perceived that the British Colleges differ as to the proportion of acid and salt. Theory calls for a little less than 82 parts of the liquid acid to 100 of the common salt; while the London College uses about 83 parts, the Dublin 87, and the Edinburgh 100 parts of acid to that quantity of salt. The London proportions are, therefore, nearest the theoretical quantities, and would even seem to furnish a slight excess of acid; but from careful experiments made by Dr. Barker of Dublin, it appears to be demonstrated, that to decompose completely the whole of the salt, 87 parts of strong acid are necessary; for it is a principle now generally conceded, and which was contended for many years ago by Dr. Hope, that to produce the complete decomposition of a salt, it is sometimes necessary to use more than an equivalent quantity of the decomposing agent. Accordingly, Dr. Hope declares, that the Edinburgh proportion of equal weights of sulphuric acid and salt gives a larger product of muriatic acid, with less expense of time and fuel, than when a smaller quantity of the decomposing acid is employed.

The common salt is purified by the Edinburgh College by dissolving it in boiling water, concentrating the solution, skimming off the crystals as they form on the surface, draining from them the adhering solution, and subsequently washing them slightly with cold water. Dr. Christison states that the object of the process is to separate nitrate of soda, which is almost always present in the common salt of commerce. It will also separate nitrate of potassa if it happen to be present. The same College directs pure sulphuric acid, on the ground that the commercial usually contains nitrous acid. (See *Acidum Sulphuricum Purum*.) The effect of a nitrate in the common salt, and of nitrous acid in the sulphuric, is to contaminate the muriatic acid with a small portion of chlorine.

Properties of the Aqueous Acid. Muriatic acid, when pure, is a transparent colourless liquid, of a corrosive taste and suffocating odour. Exposed to the air, it emits white fumes, owing to the escape of the acid gas, and its union with the moisture of the atmosphere. When concentrated, it blackens organic substances like sulphuric acid. Its sp. gr. varies with its strength. When as highly concentrated as possible, its density is 1.21. The *medicinal acid* has the sp. gr. of 1.16, and 100 grains of it saturate 132 grains of crystallized carbonate of soda. When of this strength it contains rather more than 33.9 per cent. of muriatic acid gas. (*Phillips.*) Mixed with nitric acid, it forms nitro-muriatic acid, or aqua regia. (See *Acidum Nitro-muriaticum.* Dub.)

As it is desirable to know, on many occasions, in chemical and pharmaceutical operations, the quantity of strong liquid acid, of acid gas, and of chlorine, contained in samples of acid of different densities, we subjoin a table by Dr. Ure, containing this information, as abridged by the late Dr. Duncan.

Table of the Quantity of Liquid Muriatic Acid of sp. gr. 1.2, of Muriatic Acid Gas, and of Chlorine, in 100 parts of Liquid Acid of different densities.

Sp. Gr.	Liquid Acid of sp. gr. 1.2	Acid Gas.	Chlorine.	Sp. Gr.	Liquid Acid of sp. gr. 1.2	Acid Gas.	Chlorine.

1.1206	60	24.466	23.805	1.0100	5	2.039	1.984

Muriatic acid is characterized by forming, on the addition of nitrate of silver, a white precipitate (chloride of silver), which is insoluble in nitric acid, but readily soluble in ammonia. It is incompatible with alkalis and most earths, with oxides and their carbonates, and with sulphuret and tartrate of potassa, tartar emetic, tartarized iron, nitrate of silver, and solution of subacetate of lead.

Adulterations. This acid, when pure, will evaporate without residue in a platinum spoon. If sulphuric acid be present, a solution of chloride of barium will cause a precipitate of sulphate of baryta, in the acid previously diluted with distilled water. Iron may be detected by saturating the dilute acid with carbonate of soda, and then adding ferrocyanuret of potassium, which will strike a blue colour in case that metal is present. Free chlorine may be discovered by the acid having the power to dissolve gold-leaf. Any minute portion of the leaf which may be dissolved, is detected by adding a solution of protochloride of tin, which will strike a purplish tint. The free chlorine is derived from the reaction of nitric or nitrous acid on a small portion of the muriatic acid, which is thus deprived of its hydrogen. These contaminating acids are derived from nitrates in the common salt, and nitrous acid in the commercial sulphuric acid, employed in the preparation of the muriatic acid. Hence it is that when free chlorine is present, nitrous acid, or some other oxide of nitrogen, is also present as an impurity.

Muriatic Acid of Commerce. This acid has the general properties of the pure aqueous acid. It has a yellow colour, owing to the presence of sesquichloride of iron, or of a minute portion of organic matter, such as cork, wood, &c. It usually contains sulphuric acid, and sometimes chlorine and nitrous acid. But the most injurious impurity to those who consume it in the arts, is sulphurous acid. To detect this, M. Girardin, Prof. of Chemistry at Rouen, has proposed a very delicate test, namely, the protochloride of tin. The mode of using the test is to take about half an ounce of the acid to be tested, and add to it two or three drachms of the protochloride. The mixture having been stirred two or three times, as much distilled water as of the protochloride is to be added. If sulphurous acid be present, the muriatic acid becomes turbid and yellow immediately upon the addition of the protochloride; and, upon the subsequent addition of the water, a slight evolution of sulphuretted hydrogen takes place, perceptible to the smell, and the liquid assumes a brown hue, depositing a powder of the same colour. The manner in which the test acts is as follows. By a transfer of chlorine, it is converted into bichloride and metallic tin, the latter of which, by reacting with the sulphurous acid, gives rise to a precipitate of the peroxide and protosulphuret of tin. (*Amer. Journ. of Pharm.* vii. 222, *from the Journ. de Pharm.*)

Another impurity occasionally present in the commercial acid, as shown by Dupasquier of Lyons, is arsenic. The immediate source of this impurity is the sulphuric acid used to prepare the muriatic acid. The sulphuric acid derives the arsenic from the sulphur from which it is manufactured, and this last from pyrites containing a little of the poisonous metal. The arsenic, when present, is in the form of a chloride, and from its volatility in this state of combination, is transferred to the purified acid, distilled from the commercial acid. This impurity is separated by diluting the acid with an equal volume of water, and passing through it sulphuretted hydrogen, which throws down the arsenic as a sulphuret. (*Amer. Journ. of Pharm.* xiii. 348, *from the Journ. de Chim. Med.*)

Muriatic acid of commerce is officinal only in the Edinburgh Pharmacopœia, and was made so for the first time in the last edition of that work. Its density is directed to be at least 1·180. Dr. Christison states that it varies in this respect from 1·180 to 1·216. Thus the commercial acid is stronger than the pure acid of the Edinburgh Pharmacopœia, and consequently more fuming. It is officinally defined to be always yellow, and commonly to contain a little sulphuric acid, oxide of iron, and chlorine.

Properties of Muriatic Acid Gas. Muriatic acid gas is a colourless elastic fluid, possessing a pungent odour, and irritating properties to the organs of respiration. It destroys life and extinguishes flame. It reddens litmus powerfully, and has the other properties of a strong acid. Its sp. gr. is 1·269. Subjected to a pressure of 40 atmospheres, at the temperature of 50°, it is condensed into a transparent liquid, to which only the name of *liquid muriatic acid* should be applied. It absorbs water with the greatest avidity, and, according to the temperature and pressure, unites with a greater or less quantity of that liquid. Water, at the temperature of 69°, takes up 464 times its volume of the gas, increasing one-third in bulk, and about three-fourths in weight. Water thus saturated constitutes the strong aqueous acid already described. With metallic oxides it forms a chloride of the metal and water.

Composition. Muriatic acid gas consists of one eq. of chlorine 35·42, and one of hydrogen 1=36·42; or of one volume of chlorine and one of hydrogen united without condensation.

Medical Properties. Muriatic acid is refrigerant and antiseptic. It is exhibited, largely diluted with water, in fevers, some forms of syphilis, and to counteract phosphatic deposits in the urine. Dr. Paris has given it with success in malignant cases of typhus and scarlatina, administered in a strong infusion of quassia. The same writer has found it one of the most efficacious remedies for preventing the generation of worms, after a free evacuation of the bowels. It proves also a good adjunct to gargles in ulcerated sorethroat and scarlatina maligna. The dose for internal exhibition is from ten to twenty minims, in a sufficient quantity of some bland fluid, as barley water or gruel. In the composition of gargles, it may be used in the proportion of from half a fluidrachm to two fluidrachms, to six fluidounces of the vehicle. The diluted acid is the most convenient form for prescribing. (See *Acidum Muriaticum Dilutum*.)

Toxicological Properties. Muriatic acid, when swallowed, is highly irritating and corrosive, but less so than sulphuric and nitric acids. It produces blackness of the lips, fiery redness of the tongue, hiccups, violent efforts to vomit, and agonizing pain in the stomach. There is much thirst, great restlessness, a dry and burning skin, and a small concentrated pulse. If the acid has been recently swallowed, white vapours of a pungent smell are emitted from the mouth. The best antidote is magnesia, which acts by saturating the acid. Soap is also useful for the same reason. In the course of the treatment, bland and mucilaginous drinks must be freely given. When inflammation supervenes, it must be treated on general principles.

Muriatic acid is a very important pharmaceutical agent. It is used by one or more of the Pharmacopœias in the preparation of tartaric acid, tartrate of antimony and potassa, oxide of antimony, tartrate of iron and potassa, muriate of morphia (*Ed.*), sulphate of quinia, bicarbonate of soda, strychnia, and precipitated sulphur. In the Edinburgh Pharmacopœia, the commercial acid is exclusively used in the formulæ, whether it performs the part of an agent, or enters as an ingredient into the preparation. Dr. Christison thinks it sufficiently pure "for all medical and most pharmaceutical purposes." We cannot agree in this opinion. In the Edinburgh Pharmacopœia, the pure acid is surplusage; as it is used in no process whatever, and is, according to Dr. Christison, unnecessary as a medicine.

Nitric acid is now officinal in three forms,—the strong, the commercial, and the diluted. The strong and commercial acids will be noticed here; the diluted, under another head. (See *Acidum Nitricum Dilutum*.) The strong acid is officinal in all the Pharmacopœias, and is directed to have the sp. gr.

1.5 in the U. S., Lond., and Ed. Pharmacopœias, and 1.49 in the Dublin. The commercial acid is a new officinal of the Edinburgh Pharmacopœia, and peculiar to it, and is defined by the College to have a density varying from 1.38 to 1.39. The strong acid is directed, in the British Pharmacopœias, to be obtained according to a given formula, but is more properly placed in the *Materia Medica* list of the U. S. Pharmacopœia, as an article to be purchased from the manufacturing chemist.

The usual process adopted in the laboratory for obtaining this acid is to add to nitrate of potassa in coarse powder, contained in a retort, an equal weight of strong sulphuric acid, poured in by means of a tube or funnel, so as not to soil the neck. The materials should not occupy more than two-thirds of the capacity of the retort. A receiver being adapted, heat is applied by means of a spirit-lamp, the naked fire, or a sand-bath, moderately at first, but afterwards more strongly when the materials begin to get solid, in order to bring the whole into a state of perfect fusion. Red vapours will at first arise, and afterwards disappear in the progress of the distillation. Towards its close they will be reproduced, and their reappearance will indicate that the process is completed.

The rationale of the process, when the ordinary acid of commerce is used, is as follows. Nitrate of potassa is a dry salt, consisting of one eq. of nitric acid and one of potassa. Liquid sulphuric acid of ordinary strength (sp. gr. 1.8433, Phillips,) consists of one eq. of dry sulphuric acid, and one and a quarter eqs. of water; and liquid nitric acid, of one eq. of dry acid, and one and a half eqs. of water. The equivalent quantities of the materials for mutual decomposition are one eq. of nitrate of potassa, and two eqs. of commercial sulphuric acid, containing two and a half eqs. of water. Two eqs. of dry sulphuric acid combine with one eq. of potassa, forming one eq. of bisulphate of potassa, which remains in the retort retaining one eq. of water; while the remaining one and a half eqs. of water from the sulphuric acid, uniting with one eq. of dry nitric acid, form one eq. of liquid nitric acid, which distils over. The nitric acid thus formed is, according to Mr. Phillips, the strongest procurable, and varies in density from 1.5033 to 1.504.

If, in the above process, the decomposition were performed by the strongest sulphuric acid, the proportions, in round numbers, would be one eq. of the salt 102, and two eqs. of sulphuric acid 98, containing two eqs. of water. Now this approaches nearly to equal weights; and when in practice an equal weight of the commercial weaker acid is taken, the increased quantity merely furnishes the additional portion of water which is necessary.

The British Colleges differ somewhat in the proportion of the materials employed for making this acid. The following is an outline of their respective processes.

The *London* College takes equal weights, (two pounds, each,) of dried nitrate of potassa and sulphuric acid. These are mixed in a glass retort, and the nitric acid is distilled by means of a sand-bath. About two hundred and seventeen grains of crystallized carbonate of soda are saturated by one hundred grains of this acid.

The *Edinburgh* College, in their new process, mixes in a glass retort equal weights of purified nitrate of potassa and of sulphuric acid, and distills into a cool receiver, with a moderate heat from a sand-bath or naked gas-flame, so long as the fused material continues to give off vapour. The pale-yellow acid, thus obtained, may be rendered colourless, by heating it gently in a retort. The nitrate is purified from the chlorides of sodium and potassium (the usual impurities) by two or more crystallizations; the absence of the chlorides being ascertained by the non-action of the nitrate of silver on

a solution of the purified salt. The Edinburgh College have dismissed their "*Acidum Nitrosum*," and substituted the above for their former faulty and wasteful process for nitric acid.

The *Dublin* College mixes one hundred parts of nitrate of potassa with ninety-seven parts of commercial sulphuric acid, "in a glass retort, and with an apparatus adapted to collecting the acid products, distils until the residuum in the retort concretes, and again becomes liquid."

The proportion of equal weights, now adopted by the Edinburgh College, after the London, is the best for operations on a small scale in the laboratory. This proportion is also preferred by Thenard. In operations on a large scale, where iron vessels are used, a strong heat applied, and water placed in the receivers to condense the acid, less sulphuric acid may be advantageously used.

Preparation of Nitric Acid for the Arts. Two strengths of this acid occur in the arts;—*double aqua fortis*, which is half the strength of concentrated nitric acid, and *single aqua fortis*, which is half as strong as the double. Aqua fortis is sometimes obtained by distilling a mixture of nitre and calcined sulphate of iron. By an interchange of ingredients, sulphate of potassa and nitrate of iron are formed, the latter of which, at the distilling heat, readily abandons its nitric acid. The sulphate of potassa is washed out of the residue, and the sesquioxide (peroxide) of iron which is left, is sold, under the name of colcothar, to the polishers of metals. The distillation is performed in large cast-iron retorts, lined on the inside with a thick layer of red oxide of iron, to protect them from the action of the acid. The acid is received in large glass vessels containing water. A considerable portion of the acid is decomposed by the heat into reddish vapours, which subsequently dissolve in the water, and absorb the oxygen which has been disengaged. The acid thus obtained is red and tolerably strong; but it is diluted with water before being thrown into commerce. The sp. gr. of this acid is about 1.22.

In France nitric acid is manufactured on the large scale from nitre and sulphuric acid in cast-iron cylinders. The cylinders are disposed horizontally across a furnace, and are strewed internally throughout their whole length with nitre. Two circular cast-iron plates, each pierced with a hole, serve to close the ends. At one end, the sulphuric acid is poured in, and by means of a stoneware tube connected with the other, the nitric acid is collected in receivers. The sulphate of potassa is removed after each operation. The iron cylinders are acted upon by the acid; yet, notwithstanding this disadvantage, the process, when conducted in such vessels, is attended with a great saving of expense.

In England, nitric acid is generally procured for the purposes of the arts, by distilling the materials in earthenware retorts, or cast-iron pots with an earthen head, connected with a series of glass or stoneware receivers containing water. The proportion of sulphuric acid employed by the manufacturer, is between one and two equivalents to one of the salt; and hence the product has an orange-red colour, which is removed by heating the acid.

In the United States, nitric acid is made on the large scale, in a distillatory apparatus, having the same general arrangement as in France and England. Sometimes a cast-iron cylinder is used as in France, and sometimes a thick cast-iron pot, with an earthenware head. The pot is set in brick-work over a fire-place, and the materials having been placed in it, the head is luted on with a fat lute, and made to communicate with two receivers, either of stoneware or glass, connected together by means of a tube. Large demijohns of glass answer the purpose of receivers very well. The incon-

densible products are made to pass by means of a tube into a portion of water. The quantity of sulphuric acid employed in different establishments, varies from one-half to two-thirds of the weight of the nitre. In a large chemical establishment in this city, which we had the pleasure of inspecting, through the kindness of the liberal proprietor, the proportions employed for a charge are 150 pounds of nitre to 84 pounds of strong sulphuric acid. Nitrate of soda, imported into the United States from Peru, has been used by some manufacturing chemists to obtain nitric acid. It yields a larger amount of acid for a given weight than the nitrate of potassa; but the residuum, sulphate of soda, is less valuable than sulphate of potassa. The latter salt, under the name of *sal enixum*, is sold to the alum makers.

Properties of Strong Nitric Acid. Nitric acid, so called from nitre, is a dense liquid, extremely sour and corrosive. It was discovered by Raymond Lully, in the 13th century, and its constituents, by Cavendish, in 1784. When perfectly pure, it is colourless; but as usually obtained, it has a straw colour, owing to the presence of nitrous acid. Exposed to the air, it emits white fumes, possessing a disagreeable odour. By the action of light, it undergoes a slight decomposition and becomes yellow. It acts powerfully on animal matter, producing its decomposition. On the living fibre it operates as a strong caustic. It stains the skin and most animal substances of an indelible yellow colour. On vegetable matter, it acts, when concentrated, by imparting oxygen, converting the carbon into carbonic acid, and the hydrogen into water. When diluted, it converts most animal and vegetable substances into oxalic, malic, and carbonic acids. The general character of its action is to impart oxygen to other bodies, which it is enabled to do in consequence of the large quantity of this principle which it contains in a state of loose combination. It acidifies sulphur and phosphorus, and oxidizes all the metals, except chromium, tungsten, columbium, cerium, titanium, osmium, rhodium, gold, platinum, and iridium. In the liquid state, it always contains water, which is essential to its existence in that state. Mixed with a certain quantity of water it forms the diluted nitric acid of the Pharmacopœias. It combines with salifiable bases and forms nitrates. When mixed with muriatic acid, mutual decomposition takes place, and a liquid is formed, capable of dissolving gold, called nitro-muriatic acid or aqua regia. (See *Acidum Nitromuriaticum*, U.S., Dub.) When of the sp. gr. 1.42, its composition being one equivalent of dry acid to four of water, it boils at 250°. When either stronger or weaker than this, it volatilizes at a lower temperature; and by losing more acid than water in the first case, and more water than acid in the second, it constantly approaches to the sp. gr. of 1.42, when its boiling point becomes stationary.

As in many chemical and pharmaceutical operations, a nitric acid below the standard strength is necessarily employed, it often becomes important to know the proportion of dry acid, and of acid of the standard strength of 1.5, contained in an acid of any given specific gravity. The following table, drawn up from experiments by Dr. Ure, gives information on these points,

Table, showing the Quantity of Liquid Nitric Acid, (sp. gr. 1.5,) and of Dry Nitric Acid, contained in 100 parts of the Acid at different Densities.

Nitric acid, when uncombined, is recognised by its dissolving copper with the production of red vapours, and by its forming nitre when saturated with potassa. When in the form of a nitrate, it is detected by its action on gold-leaf, after the addition of muriatic acid, in consequence of the evolution of chlorine; or it may be discovered, according to Dr. O'Shaughnessy, by heating the supposed nitrate in a test tube with a drop of sulphuric acid, and then adding a crystal of morphia. If nitric acid be present, it will be set free by the sulphuric acid, and reddened by the morphia. The same effect is produced by brucia; as also by commercial strychnia, on account of its containing brucia. To prevent all ambiguity, arising from the accidental presence of nitric acid in the sulphuric acid employed, the operator should satisfy himself by a separate experiment, that the latter acid has no power to produce the characteristic colour with morphia. (*Turner's Chemistry, Sixth Amer. edit. p. 184.*)

The most common impurities in nitric acid are sulphuric acid and chlorine; the former derived from the acid used in the process, the latter from common salt, which is not an unfrequent impurity in nitre. They may be detected by adding a few drops of the solution of chloride of barium and of nitrate of silver to separate portions of the nitric acid, diluted with three or four parts of distilled water. If these precipitants should produce a cloud, the chloride will indicate sulphuric acid, and the nitrate, chlorine. These impurities may be separated by adding nitrate of silver in slight excess, which will precipitate them as chloride and sulphate of silver, and then distilling nearly to dryness in very clean vessels. The sulphuric acid may also be got rid of by distilling from a fresh portion of nitre. These impu-

rities, however, do not in the least affect the medicinal properties of the acid.

Properties of the Nitric Acid of Commerce. This has the general properties of the strong acid. The Edinburgh acid of commerce is characterized as colourless or nearly so, and, if diluted with distilled water, as precipitating but slightly, or not at all, with solution of nitrate of baryta, or of nitrate of silver. According to M. Lemberg of Lyons, the nitric acid of commerce sometimes contains iodine, probably derived from the native nitrate of soda, in which he detected iodine. It may be detected by saturating the suspected acid with a carbonated alkali, pouring in a little clear solution of starch, and then adding a few drops of sulphuric acid. If iodine be present, the sulphuric acid will set it free, and the starch solution will become blue. (*Journ. de Pharm. Avril, 1842.*)

Composition. The officinal nitric acid consists of one eq. of dry acid 54·15, and one and a half eqs. of water 13·5=67·65. The dry acid consists of one eq. of nitrogen 14·15, and five eqs. of oxygen 40=54·15; or in volumes of one volume of nitrogen, and two and a half volumes of oxygen, supposed to be condensed, to form nitric acid vapour, into one volume. The strongest possible liquid acid consists of one equiv. of dry acid and one equiv. of water, and has the sp. gr. 1·513. (*Thenard.*)

Incompatibles. Most of the substances with which nitric acid is incompatible, may be inferred from what has been already said. It is incompatible with the sulphate of protoxide of iron, which it converts into the sulphate of the sesquioxide, with salifiable bases, carbonates, and sulphurets, and with the acetates of lead and potassa. It is also capable of decomposing alcohol, with which it forms an ether.

Medical Properties. Nitric acid is tonic and antiseptic. Largely diluted with water, it forms a good acid drink in febrile diseases, especially typhus. In syphilis, and in the chronic hepatitis of India, it is highly extolled by Dr. Scott, formerly of Bombay. It has occasionally excited pytalism. It cannot be depended upon as a remedy in syphilis, but is often an excellent adjuvant in worn-out constitutions, either to prepare the system for the use of mercury, or to lessen the effects of that metal on the constitution. Externally, it has been used with advantage as a lotion to ulcers, of the strength of about twelve minims to the pint of water. This practice originated with Sir Everard Home, and is particularly applicable to those ulcers which are superficial and not disposed to cicatrize. In sloughing phagedæna, strong nitric acid is one of the best applications, applied by means of a piece of lint, tied round a small stick. As nitric acid dissolves both uric acid and the phosphates, it was supposed to be applicable to those cases of gravel in which the uric acid and the phosphates are mixed; but experience has not confirmed its efficacy in such cases. Nevertheless, when the sabulous deposit depends upon certain states of disordered digestion, this acid may prove serviceable by restoring the tone of the stomach. The dose is from five to twenty minims in three fluidounces or more of water, given three or four times a day. The diluted acid is more convenient for prescription.

Nitric acid, in the state of vapour, is considered useful for destroying contagion; and hence is employed in purifying gaols, hospitals, and ships, and other infected places. It is prepared for use by the extemporaneous decomposition of nitre by sulphuric acid. Half an ounce of powdered nitre is put into a saucer, which is placed in an earthen dish containing heated sand. On the nitre, two drachms of sulphuric acid are then poured, and the nitric acid fumes are immediately disengaged. The quantities just indicated are considered to be sufficient for disinfecting a cubic space of ten

feet. Fumigation in this manner was first introduced by an English physician, Dr. Carmichael Smyth, who received from the British Parliament for its discovery, a reward of five thousand pounds. It may well be doubted whether the nitric acid, as a disinfectant, is at all comparable to chlorine; and since the introduction of chlorinated lime and chlorinated soda as disinfecting agents, this gas has been brought into so manageable a form, that its use may very well supersede that of every other agent employed with similar intentions. (See *Calx Chlorinata*, and *Liquor Sodæ Chlorinatæ*.)

Properties as a Poison. Nitric acid, in its concentrated state, is one of the mineral poisons most frequently taken for the purpose of self-destruction. Immediately after swallowing it, there are produced burning heat in the mouth, œsophagus and stomach, acute pain, disengagement of gas, abundant eructations, nausea and hiccup; which are soon followed by repeated and excessive vomiting of matter having a peculiar odour and taste, tumefaction of the abdomen with exquisite tenderness, a feeling of coldness on the surface, horripilations, icy coldness of the extremities, small depressed pulse, horrible anxieties, continual tossings and contortions, and extreme thirst. The breath becomes extremely fetid, and the countenance exhibits a complete picture of suffering. The cases are almost uniformly fatal. The best remedies are repeated doses of magnesia as an antidote, mucilaginous drinks in large quantities, olive or almond oil in very large doses, emollient fomentations, and clysters. Until magnesia can be obtained, an immediate resort to a solution of soap in large amount will be proper.

† ACIDUM PYROLIGNEUM. *Ed.*

Pyroligneous Acid.

“Diluted acetic acid, obtained by the destructive distillation of wood.” *Ed.*
Acide pyro-ligneux, Fr.; *Brenzliche Holzsäure, Holzessig, Germ.*; *Acido pyrolignico, Ital.*

Wood, when charred, yields many volatile products, among which are an acid liquor, empyreumatic oil, and tar containing creasote and some other newly discovered proximate principles. When the carbonization is performed in close vessels, these products, which are lost in the ordinary process of charring, may be collected, and at the same time, a large amount of charcoal is obtained.

Carbonization in close vessels, with a view to preserve the condensable volatile products, was first put in practice by Mollerat in France. The apparatus employed at Choisy, near Paris, is thus described by Thenard. It

consists of, 1st, a furnace with a moveable top; 2d, a strong sheet-iron cylinder, sufficiently capacious to contain a cord of wood, and furnished with a sheet-iron cover; 3d, a sheet-iron tube proceeding horizontally from the upper and lateral part of the cylinder to the distance of about a foot; 4th, a copper tube connected with the last, which is bent in such a manner as to plunge successively to the bottom of two casks filled with water, and, after rising out of the second, is bent back, and made to terminate in the furnace. At the bottom of each cask, the tube dilates into a ball, from the under part of which another tube proceeds, which, passing water-tight through the cask, terminates above a vessel, intended to receive the condensable products.

The sheet-iron cylinder, being filled with wood, and closed by luting on its cover with fire-clay, is let down into the furnace by the help of a crane. The fire is then applied, and when the process is completed, the cylinder is removed by the same means, to be replaced by another. During the carbonization, the volatile products are received by the tube; and those which are condensable, being the pyroligneous acid and tar, are condensed by the water in the casks, and collect in the lower bends of the tubes, from which they run into the several recipients; while the incondensable products, being inflammable gases, are discharged into the furnace, where, by their combustion, they assist in maintaining the heat. Eight hundred pounds of wood afford, on an average, thirty-five gallons of acid liquor, weighing about three hundred pounds.

This is the crude pyroligneous acid, sometimes called *pyroligneous vinegar*. It is a dark brown liquid, having a strong smoky smell, and consists of acetic acid, diluted with more or less water, and holding in solution tar and empyreumatic oil.

The Edinburgh officinal pyroligneous acid is this crude acid purified. Its purification is effected by repeated distillation, and then neutralizing it with lime or carbonate of soda. The acetate formed is decomposed by sulphuric acid, and the disengaged acetic acid repeatedly distilled, until it is obtained nearly colourless.

Properties. The pyroligneous acid of the Edinburgh College is a pale straw-coloured liquid, having a strong acetic odour, scarcely empyreumatic if well prepared. Its density must be at least 1.034. One hundred minims of acid of this density neutralize fifty-three grains of carbonate of soda. The acid is often stronger than this. The Scotch acid has sometimes the density of 1.042, and the English, a specific gravity nearly as high as 1.050. (*Christison, Ed. Dispensatory.*) As tests of its freedom from copper, lead and sulphuric acid, the Edinburgh College directs that it should be "unaffected by sulphuretted hydrogen or solution of nitrate of baryta."

Thus it appears that this new officinal of the Edinburgh College is nothing else than acetic acid, whose density is not to be under 1.034, but may be higher. This want of precision in the specific gravity of the acid is objectionable. The name too, given by the College, is indefensible. A complex product of distillation, characterized by the presence of an acid, may be designated by an unchemical name; but the convenience of such a nomenclature is no reason why the acid, when separated, should be called by the same name, merely on account of its source. On the contrary, the nature of the acid and not its source should determine its appellation. Dr. Christison insists that the acetic acid of the London College is really pyroligneous acid; because it is prepared from acetate of soda, which is usually made from the acid obtained from wood by destructive distillation!

Medical Properties and Uses. Pyroligneous acid, as defined by the Edinburgh College, is an acetic acid of medium strength, and, therefore,

applicable to the general purposes of that acid. It is accordingly employed by the College in forming several acetates. Dr. Christison states that it is useful for preserving vegetable specimens, such as pulpy fruits, bulbs, and fresh leaves.

Uses of the Crude Acid. The crude acid, in a dilute state, has been used as an application to gangrene, and ill-conditioned ulcers. It acts on the principle of an antiseptic and stimulant, the former property being probably chiefly due to the presence of creasote. Several cases in which it was successfully employed, are reported in a paper by Dr. T. Y. Simons, of Charleston, S. C., published in the fifth volume of the American Journal of Medical Sciences.

The crude acid is advantageously applied to the preservation of animal food. Mr. William Ramsay, (*Edin. Phil. Journ.* iii. 21,) has made some interesting experiments on its use for that purpose. Herrings and other fish, simply dipped in the acid and afterwards dried in the shade, were effectually preserved, and when eaten, were found very agreeable to the taste. Herrings slightly cured with salt, by being sprinkled with it for six hours, then drained, next immersed in pyroligneous acid for a few seconds, and afterwards dried in the shade for two months, were found by Mr. Ramsay to be of fine quality and flavour. Fresh beef, dipped in the acid in the summer season for the short space of a minute, was perfectly sweet in the following spring. Professor Silliman states, that one quart of the acid added to the common pickle for a barrel of hams, at the time they are laid down, will impart to them the smoked flavour as perfectly as if they had undergone the ordinary process of smoking.

Oil of vitriol; Acide sulphurique, *Fr.*; Vitriolöl, Schwefelsäure, *Germ.*; Acido solforico, *Ital.*; Acido sulfurico, *Span.*

Sulphuric acid is placed in the *Materia Medica* of all the Pharmacopœias noticed in this work, as an article to be obtained from the wholesale manufacturer. Its officinal sp. gr., as prescribed in the U. S. and London Pharmacopœias, is 1·845; in the Edinburgh, 1·840; and in the Dublin, 1·850.

Preparation. Sulphuric acid is obtained by burning sulphur, mixed with one-eighth of its weight of nitre, over a stratum of water, contained in a chamber lined with sheet lead. If the sulphur were burned by itself, the product would be sulphurous acid, which contains only two-thirds as much oxygen as sulphuric acid. The object of the nitre is to furnish, by its decomposition, the requisite additional quantity of oxygen. To understand the process, it is necessary to bear in mind that nitric acid contains five, sulphuric acid three, sulphurous acid two, nitric oxide two, hyponitrous acid three, and nitrous acid four equivalents of oxygen, combined with one equiv. of their several radicals. One equiv. of sulphur decomposes one equiv. of nitric acid of the nitre, and becomes one equiv. of sulphuric acid, which combines with the potassa of the nitre to form sulphate of potassa.

In the mean time, the nitric acid, by furnishing three equiv. of oxygen to form the sulphuric acid, is converted into one equiv. of nitric oxide, which is evolved. This gas, by combining with two equiv. of the oxygen of the air, immediately becomes nitrous acid vapour, which diffuses itself throughout the leaden chamber. While these changes are taking place, the remainder of the sulphur is undergoing combustion, and filling the chamber with sulphurous acid gas. One equiv. of nitrous acid gas, and one equiv. of sulphurous acid gas, being thus intermingled in the chamber, react on each other by the aid of moisture, so as to form a crystalline compound, consisting of one equiv. of sulphuric acid, and one equiv. of hyponitrous acid united with a portion of water. This compound falls into the water of the chamber, and instantly undergoes decomposition. The sulphuric acid dissolves in the water, and the hyponitrous acid, resolved, at the moment of its extrication, into nitrous acid and nitric oxide, escapes with effervescence. The nitrous acid thus set free, as well as that reproduced by the nitric oxide uniting with the oxygen of the atmosphere, again reacts with sulphurous acid and humidity, and gives rise to a second portion of the crystalline compound, which undergoes the same changes as the first. In this manner the nitric oxide performs the part of a carrier of oxygen from the air of the chamber to the sulphurous acid, to convert the latter into sulphuric acid. The residue of the combustion of the sulphur and nitre consists of sulphate of potassa, and is sold to the alum makers.

Preparation on the Large Scale. The leaden chambers vary in size, but are generally from thirty to thirty-two feet square, and from sixteen to twenty feet high. The floor is slightly inclined to facilitate the drawing off of the acid, and covered to the depth of several inches with water. There are several modes of burning the mixture of sulphur and nitre, and otherwise conducting the process, but that pursued in France is as follows. Near to one of the sides of the chamber, and at about a foot from its bottom, a cast iron tray is placed over a furnace, resting on the ground, its mouth opening externally, and its chimney having no communication with the chamber. On this tray the mixture is placed, being introduced by a square opening which may be shut by means of a sliding door, and the lower side of which is level with the surface of the tray. The door being shut, the fire is gradually raised in the furnace, whereby the sulphur is inflamed, and the products already spoken of are generated. When the combustion is over, the door is raised, and the sulphate of potassa removed. A fresh portion of the mixture is then placed on the tray, and the air of the chamber is renewed by opening a door and valve situated at its opposite side. Next, the several openings are closed, and the fire is renewed. These operations are repeated with fresh portions of the mixture, every three or four hours, until the water at the bottom of the chamber has reached the sp. gr. of about 1.5. It is then drawn off and transferred to leaden boilers, where it is boiled down until it has attained the sp. gr. of 1.7. At this density it begins to act on lead, and, therefore, its further concentration must be conducted in large glass or platinum retorts, where it is evaporated as long as water distils over. This water is slightly acid and is thrown back into the chamber. When the acid is fully concentrated, opaque grayish-white vapours arise, the appearance of which indicates the completion of the process. The acid is allowed to cool, and is then transferred to large demijohns of green glass, called carboys, which, for greater security, are surrounded with straw or wicker-work, and packed in square boxes, or in flour barrels sawed in two.

The method of manufacturing this acid, as described by Mr. Parkes, is

somewhat different. The mixture is usually spread on iron or leaden plates, resting on stands of lead within the chamber, placed at some distance from each other, and a foot or two above the surface of the water. The sulphur is then lighted by means of a hot iron, and the doors closed. If the sulphur and nitre be well mixed, the combustion will last for thirty or forty minutes; and in three hours from the time of lighting, the condensation of the gases having in that interval been completed, the doors are thrown open for from fifteen to thirty minutes, to admit fresh atmospheric air, and to allow time for the residuary nitrogen to escape, preparatory to the next burning. These operations are repeated with fresh charges of the mixture, every four hours, both night and day, until the water has attained the requisite acid impregnation, when it is transferred to leaden boilers, and otherwise treated as just explained. The quantity of the charge for each burning is determined by the size of the chamber, allowing one pound of the mixture for every three hundred cubic feet of atmospheric air which it may contain.

As, in the manufacture of sulphuric acid, the nitre is the most expensive material, many plans have been resorted to, for the purpose of obtaining the nitrous acid at a cheaper rate. One plan is to procure it by treating molasses or starch with common nitric acid. In this case, the manufacturer obtains oxalic acid as a collateral product, which serves to diminish his expenses.

In some manufactories of sulphuric acid, nitrate of soda is substituted for nitre. The advantages of the former salt are its greater cheapness, and the circumstance of its containing a larger proportional quantity of nitric acid.

A new method is now practised by some manufacturers for making sulphuric acid. It consists in filling the leaden chamber with sulphurous acid, by the ordinary combustion of sulphur, and afterwards admitting into it nitrous acid and steam. The nitrous acid is generated from a mixture of sulphuric acid with nitrate of potassa or nitrate of soda, placed in an iron pan, over the burning sulphur in the sulphur furnace, where the draught serves to conduct the nitrous acid fumes into the chamber. As, under these circumstances, sulphurous and nitrous acid, and the vapour of water are intermingled in the chamber, it follows that all the conditions necessary for generating the crystalline compound, already alluded to, are present. Of course, the rationale of this new process is the same as that already given. The details of this process, and a wood-cut of the sulphur furnace, steam boiler, and chamber employed, are given by Dr. Pereira in his *Materia Medica, Second Edition*, p. 465.

The above explanations relate to the mode of preparing common sulphuric acid; but there is another kind known on the continent of Europe by the name of the *fuming sulphuric acid of Nordhausen*, so called from its properties, and a place in Saxony where it is largely manufactured. This acid is obtained by distilling dried sulphate of iron in large stoneware retorts, heated to redness, and connected with receivers of glass or stoneware. The acid distils over, and sesquioxide of iron is left behind in the form of *colcothar*.

The process for making sulphuric acid by the combustion of sulphur with nitre was first mentioned by Lemery, and afterwards put in practice by an English physician of the name of Ward. As practised by him, the combustion was conducted in very large glass vessels. About the year 1746, the great improvement of leaden chambers was introduced by Dr. Roebuck, an eminent physician of Birmingham, where the first apparatus of this kind

was erected. In consequence of this improvement, the acid immediately fell to one-fourth of its former price, and was employed for many purposes for which previously it could not be used, on account of its cost.

In the United States, the first manufactory of this acid was established in Philadelphia by the late Mr. John Harrison. At present there are manufactories in successful operation in most of the cities of the Union. These supply the entire demand of the United States.

Properties. Sulphuric acid, or, as it is commonly called, oil of vitriol, is a dense, colourless, inodorous liquid, of an oleaginous appearance, and possessing strong corrosive qualities. On the living fibre, it acts as a powerful caustic. Rubbed in small quantity between the fingers, it has an unctuous feel, in consequence of its dissolving the cuticle. In the liquid form, it always contains water, which is essential to its existence in that form. When pure and as highly concentrated as possible, its sp. gr. is 1.845, a fluidounce weighing a small fraction over fourteen drachms. When of this specific gravity, it contains about 18 per cent. of water. Whenever its density exceeds this, the presence of sulphate of lead, or of some other impurity is indicated. The commercial acid is seldom of full strength. According to Mr. Phillips, it is generally only about 1.8433, and contains 22 per cent. of water. The commercial acid of the Edinburgh College is stated to have the density of 1.840 or near it. The strong acid boils at 545° , and freezes at 15° below zero. When diluted, its boiling point is lowered. When of the sp. gr. 1.78, it freezes above 32° ; and hence it is hazardous for manufacturers to keep an acid of that strength in glass vessels in cold weather, as they are liable to burst. With salifiable bases, it forms a numerous class of salts called sulphates. It acts powerfully on organic bodies, whether vegetable or animal, depriving them of the elements of water, developing charcoal, and turning them black. A small piece of cork or wood dropped into the acid, will, on this principle, render it of a dark colour. When diluted with pure water, it ought to remain limpid, and when heated sufficiently in a platinum spoon, the fixed residue should not exceed the four-hundredth part of the acid employed. When present in small quantities in solution, it is detected unerringly by chloride of barium, which causes a precipitate of sulphate of baryta. The most usual impurities in it are the sulphates of potassa and lead, the former derived from the residue on the iron tray, the latter from the leaden boilers in which the acid is concentrated. Occasionally nitre is added to render dark samples of acid colourless. This addition will give rise to the impurity of sulphate of potassa. These impurities often amount to three or four per cent. The commercial acid cannot be expected to be absolutely pure; but, when properly manufactured, it ought not to contain more than one-fourth of one per cent. of impurity. The fixed impurities are discoverable by evaporating a portion of the suspected acid, when they will remain. If sulphate of lead be present, the acid will become turbid on dilution with an equal bulk of water. If only a scanty muddiness arises, the acid is of good commercial quality. Freedom from metallic impregnation is shown by the diluted acid not being coloured by sulphuretted hydrogen.

Other impurities occur in the commercial sulphuric acid. Nitrous acid is always present in more or less amount. It may be detected by gently pouring a solution of green vitriol over the commercial acid in a tube; when the solution, at the line of contact, will acquire a deep red colour, due to the sesquioxidation of the iron by the nitrous acid. The commercial acid is not to be rejected on account of the indications of this test, unless it shows the presence of nitrous acid in unusual quantity. When sulphate of

potassa is fraudulently introduced into the acid to increase its density, it may be detected by saturating the acid with ammonia and heating to redness in a crucible; when the sulphate of ammonia will be expelled, and the sulphate of potassa left behind. The dangerous impurity of arsenious acid is sometimes present in sulphuric acid. In consequence of the high price of Sicilian sulphur, some of the English manufacturers have employed iron pyrites for the purpose of furnishing the necessary sulphurous acid in the manufacture of oil of vitriol. With this view the pyrites is subjected to combustion, and the sulphurous acid fumes are conducted into the leaden chamber. As the pyrites usually contains arsenic, it happens that the sulphurous acid fumes are accompanied by arsenious acid, and thus the sulphuric acid becomes contaminated. From 22 to 35 grains of arsenious acid have been found in 20 fluidounces of oil of vitriol of English manufacture, by Dr. G. O. Rees and Mr. Watson. To detect this impurity, the acid, previously diluted with distilled water, must be examined by Marsh's test, or subjected to a stream of sulphuretted hydrogen. (See *Acidum Arseniosum*.)

As sulphuric acid is often under the standard strength, it becomes important to know how much liquid sulphuric acid of the standard specific gravity, and of dry acid, is contained in an acid of any given density. The following table, drawn up from careful experiments by Dr. Ure, gives this information. In using it, the specific gravity of any sample of the acid is first ascertained by experiment; and then, opposite to this specific gravity in the table, will be found the quantity, per cent., of standard liquid acid and of dry acid contained in it.

Table of the Quantity of Liquid Sulphuric Acid of Sp. Gr. 1·8485, and of Dry Acid, in 100 parts of Dilute Acid at different Densities.

Sp. Gr.	Liq. Acid in 100	Dry Acid in 100	Sp. Gr.	Liq. Acid in 100	Dry Acid in 100	Sp. Gr.	Liq. Acid in 100	Dry Acid in 100	Sp. Gr.	Liq. Acid in 100	Dry Acid in 100

The only way to obtain pure sulphuric acid is by distillation. Owing to the high boiling point of this acid, the operation is rather precarious, in con-

sequence of the danger of the fracture of the retort, from the sudden concussions to which the boiling acid gives rise. Dr. Ure recommends that a retort of the capacity of from two to four quarts be used in distilling a pint of acid. This is connected, by means of a wide glass tube three or four feet long, with a receiver surrounded with cold water. All the vessels must be perfectly clean, and no luting is employed. The retort is then to be cautiously heated by a small furnace of charcoal. It is useful to put into the retort a few sharp-pointed pieces of glass, or slips of platinum foil, with the view of diminishing the shocks produced by the acid vapour. The distilled product ought not to be collected until a dense grayish-white vapour is generated, the appearance of which is the sign that the pure concentrated acid is coming over. If this vapour should not immediately appear, it shows that the acid subjected to distillation is not of full strength, and the distilled product, until the point of utmost concentration is attained, will be an acid water.

The Edinburgh and Dublin Colleges give formulæ for purifying the commercial acid. (See *Acidum Sulphuricum Purum*.) The strong acid is not convenient for medicinal use; and hence a formula for a diluted acid is given in the United States Pharmacopœia, following the example of the British Colleges. (See *Acidum Sulphuricum Dilutum*.)

Incompatibles. Sulphuric acid is incompatible with most metals; with salifiable bases and their carbonates; with most salts, effecting their decomposition; with alcohol, which it converts into ether; with all organic substances, which it chars or otherwise decomposes; and with vegetable astringent solutions.

Composition. The liquid acid of the sp. gr. 1·845, consists of one equivalent of dry acid 40·1, and one equiv. of water 9=49·1; and the dry acid, of one equiv. of sulphur 16·1, and three equiv. of oxygen 24=40·1. The ordinary commercial acid (sp. gr. 1·8433) consists, according to Mr. Phillips, of one equiv. of dry acid, and one and a quarter equiv. of water; or four equiv. of the former to five of the latter. The liquid acid of Nordhausen has a density as high as 1·89 or 1·9, and consists of two equiv. of dry acid, and one equiv. of water. This acid is particularly adapted to the purpose of dissolving indigo for dyeing the Saxon blue. When heated gently in a retort, connected with a dry and refrigerated receiver, dry or anhydrous sulphuric acid distils over, and the common liquid acid remains behind. The anhydrous acid under 64° is in the form of small colourless crystals, resembling asbestos. It is tenacious, difficult to cut, and may be moulded in the fingers like wax, without acting on them. Exposed to the air, it emits a thick opaque vapour of an acid smell. Above 64° it is a liquid, very nearly of the density of 2. It has so strong an affinity for water, that when thrown into that liquid, it causes a hissing noise, like that produced by quenching red-hot iron.

Medical Properties. Sulphuric acid is tonic, antiseptic, and refrigerant. Internally it is always administered in a dilute state. For its medical properties in this form, the reader is referred to the title, *Acidum Sulphuricum Dilutum*. Externally it is sometimes employed as a caustic; but, from its liquid form, it is very inconvenient for that purpose. It is employed also as an ointment mixed with lard, in swellings of the knee-joint and other affections, in the proportion of a drachm to an ounce. (See *Unguentum Acidi Sulphurici*, Dub.) Charpie, corroded by it, forms a good application to gangrene.

Toxicological Properties. The symptoms of poisoning by this acid are the following:—Burning heat in the throat and stomach, extreme fetidness

of the breath, nausea and excessive vomitings of black or reddish matter, excruciating pains in the bowels, difficulty of breathing, extreme anguish, a feeling of cold on the skin, great prostration, constant tossing, convulsions, and death. The intellectual faculties remain unimpaired. Frequently the uvula, palate, tonsils, and other parts of the fauces, are covered with black or white sloughs. The treatment consists in the administration of large quantities of magnesia, or, if this is not at hand, of a solution of soap. The safety of the patient depends upon the greatest promptitude in the application of the antidotes. After the poison has been neutralized, mucilaginous and other drinks must be taken in large quantities.

Uses in the Arts. Sulphuric acid is more used in the arts than any other acid. It is employed to obtain nearly all other acids; to extract soda from common salt; to make alum and sulphate of iron, when these salts command a good price, and the acid is cheap; to dissolve indigo; to prepare skins for tanning; to prepare phosphorus, chlorinated lime or bleaching salt, sulphate of magnesia, &c. The arts of bleaching and dyeing cause its principal consumption.

Sulphuric acid is used as a chemical agent, in one or more of the Pharmacopœias commented on in this work, for preparing the following officinals:—acetic, hydrocyanic, muriatic, and nitric acids; sulphuric ether and spirit of nitric ether; carbonic acid water and chlorine water; ferrocyanuret, hydrated oxide, and black oxide of iron; mild and corrosive chlorides of mercury; solution of chlorinated soda; bicarbonates of potassa and soda; and phosphate of soda.

ACIDUM TARTARICUM. *U. S., Lond., Ed., Dub.*

Tartaric Acid.

Acide tartrique, *Fr.*; Weinstensäure, *Germ.*; Acido tartarico, *Ital., Span.*

Tartaric acid is officinal in all the Pharmacopœias commented on in this work. It is placed among the preparations by the British Colleges; but stands more properly, in the United States Pharmacopœia, in the *Materia Medica*, as an article to be purchased from the wholesale manufacturer. It is extracted from tartar, a peculiar substance which concretes on the inside of wine-casks, being deposited there during the fermentation of the wine. Tartar, when purified and reduced to powder, is the cream of tartar of the shops, and is found to be a supersalt, consisting of two equivalents of tartaric acid and one of potassa. It is, therefore, in correct chemical language, a bitartrate of potassa. (See *Potassæ Bitartras.*)

Tartaric acid was first obtained in a separate state by Scheele in 1770. The process consists in saturating the excess of acid in the bitartrate of potassa with carbonate of lime, and decomposing the resulting insoluble tartrate of lime by sulphuric acid, which precipitates in combination with the lime, and liberates the tartaric acid. The equivalent quantities are one equiv. of bitartrate, and one of carbonate of lime. The process, when

thus conducted, furnishes the second equivalent or excess of acid only of the bitartrate. The other equivalent may be procured by decomposing the neutral tartrate of potassa, remaining in the solution after the precipitation of the tartrate of lime, by chloride of calcium in excess. By double decomposition, chloride of potassium will be formed in solution, and a fresh portion of tartrate of lime will precipitate, which may be decomposed by sulphuric acid in the same manner as the first portion. The process, when thus conducted, will furnish twice as much tartaric acid as when the excess of acid only is saturated and set free.

Preparation on the Large Scale. The mode of obtaining this acid on the large scale is as follows. Mix intimately, by grinding in a mortar and passing through a sieve, 100 parts of bitartrate of potassa (cream of tartar) with $26\frac{1}{2}$ parts of pulverized chalk. Throw the mixture, by spoonfuls, into 8 or 10 times its weight of boiling water, waiting until the effervescence has ceased, before every fresh addition. Examine the solution by litmus paper, and if not neutral, make it so by the addition of a little chalk. Wash the tartrate of lime with abundance of cold water, and add to it a quantity of sulphuric acid equal in weight to the chalk employed, and diluted with from 10 to 16 times its weight of water. Agitate the mixture frequently for 24 hours, and then test a small portion of the clear solution for sulphuric acid by acetate of lead. A precipitate will be formed, which is either tartrate of lead, or a mixture of tartrate and sulphate of lead. If the former, it will dissolve entirely in dilute nitric acid; if the latter, only partially, as the sulphate of lead is insoluble in that acid. If a slight excess of sulphuric acid should be indicated, it is of no consequence; but if the excess be considerable, it must be removed by a fresh addition of chalk. On the other hand, an excess of tartrate of lime, which interferes very much with the crystallization of the tartaric acid, must be decomposed by adding a small quantity of sulphuric acid. The clear liquor, separated from the sulphate of lime, is concentrated by evaporation to the consistence of syrup, and allowed to crystallize. Repeated solutions and crystallizations are necessary to get the crystals white. The mode of ascertaining the quantity of chalk consumed, is to weigh out more than is necessary in the process, and, after the saturation has been completed, to weigh what is left. If the neutral tartrate of potassa be also converted into tartrate of lime in the manner already explained, the quantity of sulphuric acid for decomposition must be doubled. Sometimes the bitartrate of potassa is decomposed by lime, in which case the whole of the tartaric acid present is converted into tartrate of lime at one operation; but the caustic potassa at the same time liberated, renders this process ineligible, by dissolving the tartrate of lime formed, and preventing it from precipitating.

The reader is now prepared to understand the formulæ of the British Colleges. In that of the London College, the Imperial measure is of course employed.

“Take of bitartrate of potassa four pounds; boiling distilled water two gallons and a half; prepared chalk twenty-five ounces and six drachms; diluted sulphuric acid seven pints and seventeen fluidounces; hydrochloric acid twenty-six and a half fluidounces, or as much as may be sufficient. Boil the bitartrate of potassa with two gallons of the distilled water, and add, by degrees, the half of the chalk; when the effervescence is over, add the remainder of the chalk, previously dissolved in the hydrochloric acid, diluted with four pints of the distilled water. Then set aside that the tartrate of lime may subside, and, having poured off the liquor, wash the tartrate frequently with distilled water until it is free from taste. Then pour on the

diluted sulphuric acid, and boil for a quarter of an hour. Having filtered the liquor, evaporate it by a gentle heat, that crystals may form. These, in order to be pure, must be dissolved in water two or three times, and the solution as often filtered, evaporated, and set aside." *Lond.*

The formula of the Edinburgh College is substantially the same as that of the London.

"Take of bitartrate of potassa, reduced to powder, ten parts; prepared chalk, four parts; sulphuric acid seven parts; water, one hundred and twenty parts. Mix the bitartrate of potassa with one hundred parts of hot water, and gradually add the prepared chalk; then, as soon as the effervescence shall have ceased, pour off the supernatant liquor. Wash the residual tartrate of lime, until it becomes tasteless. Into the clear decanted liquor, drop as much of the water of muriate of lime as may be sufficient to throw down the tartrate of lime. Let this also be washed with water, and mixed with the former deposite. Then add the sulphuric acid, diluted with twenty parts of water, and, employing frequent agitation, digest the mixture with a *medium* heat during three days. Pour off the supernatant acid fluid, and wash out the acid from the sediment. Let the liquors, including the first acid liquor and the washings, evaporate with a gentle heat to the point of crystallization. Let the crystals, purified by repeated solutions and crystallizations, be kept in a stopped glass vessel." *Dub.*

The quantity of chalk directed in the Dublin formula is excessive, being two-fifths of the weight of the bitartrate; whereas, by theory, a portion only one-fourth the weight of the latter is required; and making every allowance for impurities, one-third would be amply sufficient. The plan of dissolving the bitartrate in boiling water and then adding the chalk, is not an eligible one. It is better to mix them together according to the plan given by Dr. Henry, as described in the beginning of this article, and to throw the mixture by spoonfuls at a time into boiling water. In this way, less water is necessary; and less excess of chalk is required, as less of it escapes decomposition. Instead of prescribing the quantity of chalk, it would, perhaps, have been an improvement, if the Colleges had directed a quantity "sufficient for saturation." The London and Edinburgh Colleges have very properly followed the example of the Dublin College, by directing the decomposition of the neutral tartrate of potassa by means of a solution of chloride of calcium.

Properties. Tartaric acid is a white crystallized solid, in the form of irregular six-sided prisms. Sometimes two opposite sides of the prism become very much enlarged, so as to cause the crystals to present the appearance of tables. It is unalterable in the air, and possesses a strong acid taste, which becomes agreeable when the acid is sufficiently diluted with water. It is soluble in five or six times its weight of cold, and twice its weight of boiling water. It is also soluble in alcohol. A weak solution undergoes spontaneous decomposition by keeping, becoming covered with a mouldy pellicle. In the form of crystals, it always contains combined water, from which it cannot be separated without the substitution of a base. In uniting with bases, it has a remarkable tendency to form double salts, several of which constitute important medicines. When subjected to heat it gives rise to three peculiar acids, described in systematic chemical works. It is distinguished from all other acids by forming a precipitate, consisting of bitartrate of potassa, when added to a neutral salt of that alkali. Its most usual impurity is sulphuric acid, which may be detected by the solution affording, with acetate of lead, a precipitate only partially soluble in nitric acid. When incinerated with red oxide of mercury, it leaves no residuum, or a mere trace.

Tartaric acid is incompatible with salifiable bases and their carbonates; with salts of potassa, with which it produces a crystalline precipitate of bitartrate; and with the salts of lime and of lead, with which it also forms precipitates. It consists when dry, of two equivalents of hydrogen 2, four equiv. of carbon 24·48, and five equiv. of oxygen 40=66·48; and when crystallized, of one equivalent of dry acid 66·48, and one equiv. of water 9=75·48.

Medical Properties. Tartaric acid, being cheaper than citric acid, forms, when dissolved in water and sweetened, a good substitute for lemonade. It is very much used in medicine to form acid refrigerant drinks and effervescing draughts. What are called *soda powders* consist of tartaric acid, and bicarbonate of soda, put up in separate papers. These powders have been made officinal in the last Edinburgh Pharmacopœia, under the name of *Pulveres Effervescentes*. Tartaric acid is also a constituent in the gentle aperient called *Seidlitz powders*. These consist of a mixture of two drachms of tartrate of potassa and soda (Rochelle salt), and two scruples of bicarbonate of soda, put up in a white paper, and thirty-five grains of tartaric acid contained in a blue one. The contents of the white paper are dissolved in about half a pint of water, to which those of the blue paper are added; and the whole is taken in a state of effervescence. The excess of acid renders the medicine more pleasant, without injuring its aperient quality. This acid, when powdered and dried by a gentle heat, and then mixed in due proportion with bicarbonate of soda, forms a good effervescing powder, a teaspoonful of which, stirred into a tumbler of water, forms the dose. The mixture must be kept in well-stopped vials. The neutralizing power of tartaric acid is about the same as that of citric acid.

Aconit, Fr.; *Eisenhut, Mönchskappe, Germ.*; *Aconito, Napello, Ital.*; *Aconito, Span.*

ACONITUM. *Sex. Syst.* Polyandria Trigynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. Calyx none. Petals five, the highest arched. Nectaries two, peduncled, recurved. Pods three or five. *Willd.*

The plants belonging to this genus are herbaceous, with divided leaves, and violet or yellow flowers, disposed in spikes, racemes, or panicles. In the French Codex three species are recognised as officinal, the *A. Anthora*, *A. Cammarum*, and *A. Napellus* of Linnæus. The Edinburgh College adopts only the *A. Napellus*, which was erroneously supposed to be the plant employed by Störck, who introduced the medicine into notice. The U. S. Pharmacopœia at present recognises the *A. Napellus* and *A. paniculatum* of De Candolle, the London and Dublin Colleges only the latter. De Candolle, in his *Prodromus*, divides the genus *Aconitum* into four sections—*Anthora*, *Lycotconum*, *Cammarum*, and *Napellus*. The *A. paniculatum* belongs to the third of these divisions; and the particular plant believed to have been used by Störck, is a variety of this species, distin-

guished in the Prodomus as the *Störckianum*. De Candolle is probably correct. The *A. neomontanum* of Willdenow, for which the honour has been generally claimed, is, according to Geiger, possessed of little acrimony, and is therefore very different from Störck's plant, which is represented as extraordinarily acid. It is, however, of little consequence which was used by Störck; as most of the species possess similar virtues, and one is frequently substituted for another in the shops. Geiger states that he has found none equal to the *A. Napellus* in acrimony; and this may, therefore, perhaps, be considered as the most efficacious. Only one species of aconite is indigenous in this country—the *A. uncinatum*. Most of the others are natives of the Alpine regions of Europe and Siberia. Those employed in medicine appear to be indiscriminately called by English writers *wolfbane* or *monkshood*.

Aconitum Napellus. Linn. *Flor. Suec. ed.* 1755, p. 186.—*A. neubergense*. De Cand. *Prodrom.* i. 62.—*A. variabile neubergense*. Hayne, *Darstel. und Beschreib. &c.*, xii. 14. This is a perennial herbaceous plant, with a turnip-shaped or fusiform root, seldom exceeding at top the thickness of the finger, three or four inches or more in length, brownish externally, whitish and fleshy within, and sending forth numerous long, thick, fleshy fibres. When the plant is in full growth, there are usually two roots joined together, of which the older is dark brown and supports the stem, while the younger is of a light yellowish-brown, and is destined to furnish the stem of the following year. The stem is erect, round, smooth, leafy, usually simple, and from two to four feet high, though it sometimes rises even six or eight feet. The leaves are alternate, petiolate, divided almost to the base, from two to four inches in diameter, deep green upon their upper surface, light green beneath, somewhat rigid, and more or less smooth and shining on both sides. Those on the lower part of the stem have long footstalks and five or seven divisions; the upper, short footstalks and three or five divisions. The divisions are narrow at their base, but widen in the form of a wedge towards their summit, and present two or three lobes, which extend nearly or quite to the middle. The lobes are cleft or toothed, and the laciniae or teeth are linear or linear-lanceolate and pointed. The flowers are of a dark violet-blue colour, large and beautiful, and are borne at the summit of the stem upon a thick, simple, straight, erect, spike-like raceme, beneath which, in the cultivated plant, several smaller racemes arise from the axils of the upper leaves. Though without calyx, they have two small calycinal stipules, situated on the peduncle within a few lines of the flower. The petals are five, the upper helmet-shaped and beaked, nearly hemispherical, open or closed, the two lateral roundish and internally hairy, the two lower oblong-oval. They enclose two pediceled nectaries, of which the spur is capitate, and the lip bifid and revolute. The fruit consists of three, four, or five podlike capsules.

The plant is abundant in the mountain forests of France, Switzerland, and Germany. It is also cultivated in the gardens of Europe, and has been introduced into this country as an ornamental flower. All parts of it are acid and poisonous. The leaves are usually employed, and should be collected when the flowers begin to appear, or shortly before. In the last edition of the London Pharmacopœia, the root also has been adopted as official. According to Dr. Turnbull, this is by far the most active part of the plant. It should be gathered in the spring, before the appearance of the leaves.

Properties. The fresh leaves have a faint narcotic odour, which is most sensible when they are rubbed. Their taste is at first bitterish and herba-

ceous, afterwards burning and acrid, and attended with a feeling of numbness and tingling on the inside of the lips, tongue, and fauces, which is very durable, lasting sometimes many hours. When long chewed, they inflame the tongue. The *dried leaves* have a similar taste, but the acrid impression commences later. Their sensible properties and medicinal activity are impaired by long keeping. They should be of a green colour, and neither musty nor tasteless. The *root* has the same effect upon the mouth and fauces. It shrinks much in drying, and assumes a darker colour. Those parcels, whether of leaves or roots, should always be rejected which are destitute of acrimony. Other species of aconite are often substituted, and, if possessed of the same sensible properties, without inconvenience. The analysis of aconite, though attempted by several chemists, has not been satisfactorily accomplished. Bucholz obtained from the fresh herb of the *A. neomontanum*, resin, wax, gum, albumen, extractive, lignin, malate and citrate of lime and other saline matters, besides 83·33 per cent. of water. During the bruising of the herb, he experienced headach, vertigo, &c., though water distilled from it produced no poisonous effect. It has been rendered probable by the researches of Geiger and Hesse, that there are two active principles in aconite, one easily destructible, upon which the acrimony depends, the other less acrid, having alkaline properties, and capable of exerting a powerful narcotic influence over the system. For the latter the name of *aconitin* has been proposed; which, however, if the claim of the principle to the rank of an alkali be admitted, should be changed to *aconitia*. Hesse obtained it from the dried leaves by a process similar to that employed in procuring atropia. (See *Belladonna*.) The London College has adopted it as officinal, and given a process for its preparation under the name of *aconitina*. (See *Aconitina*, in the second part of this work.) Peschier discovered a peculiar acid in aconite, which he called *aconitic acid*.

Medical Properties and Uses. Aconite was well known to the ancients as a powerful poison, but was first employed as a medicine by Baron Störck of Vienna, whose experiments with it were published in the year 1762. In moderate doses it is said to excite the circulation, and occasionally to increase the perspiratory and urinary discharge, while it exercises considerable influence over the nervous system. Recent writers, however, deny that it possesses any decided diaphoretic or diuretic properties. Among its effects, when it is pretty freely given, are, according to Turnbull, headach, nausea, weakness of the joints and muscles, slight confusion of intellect, and a remarkable sensation of tingling in various parts of the body, particularly in the head, face, and extremities. In poisonous doses, besides the effects on the mouth and throat already mentioned, it occasions burning heat of the stomach, thirst, violent nausea, vomiting, purging, severe gastric and intestinal spasms, headach, dimness of vision with contracted or expanded pupil, numbness or paralysis of the limbs, diminished sensibility in general, stiffness of the muscles, great prostration of strength, pallid countenance, cold extremities, an extremely feeble pulse, and death in a few hours, sometimes preceded by delirium, stupor, or convulsions. All these effects are not experienced in every case, but there is no one of them which has not been recorded as having occurred in one or more instances. Dissection reveals inflammation of the stomach and bowels, and engorgement of the brain and lungs. Life may usually be saved by a timely and thorough evacuation of the stomach, and the use of stimulant remedies internally and externally. Pereira states that, when dogs are opened immediately after death from aconite, no pulsations of the heart are visible. (*Elements of Mat. Med., &c.*) Applied to the skin, aconite is said to occasion a feeling of heat and prickling

or tingling followed by numbness, (*Turnbull*), and if in contact with a wound produces its peculiar constitutional effects. Applied to the eye, it causes contraction of the pupil. (*Pereira*.) In relation to its mode of action, aconite appears to be locally irritant, and, at the same time, entering the system, to operate powerfully on the brain, spinal marrow, and nerves, directly diminishing their power, and thus producing, to a greater or less extent, paralysis both of sensation and motion. The heart feels also this paralyzing influence, and hence proceeds the great depression of the pulse under the full action of the medicine.

Aconite has been employed in rheumatism, neuralgia, gout, scrofula, phthisis, secondary syphilis, scirrhus and cancer, certain cutaneous diseases, amaurosis, paralysis, epilepsy, intermittent fever, dropsies, and other complaints. Professor Fouquier, who experimented largely with it in the *Hôpital de la Charité*, found little advantage from its use, except as a diuretic in passive dropsy. It has long enjoyed, in Germany, a high reputation as a remedy in rheumatism; and has recently come into great vogue elsewhere in the treatment of that disease, especially in its chronic and neuralgic forms. By some practitioners it is considered as one of the most effectual remedies in neuralgia, in which it is used both internally and as a local application. It may be administered in powder, extract, or tincture. The dose of the powdered leaves is one or two grains, of the extract from half a grain to a grain, of the tincture twenty or thirty drops, to be repeated twice or three times a day, and gradually increased till the effects of the medicine are experienced. Dr. *Turnbull* recommends a tincture made from the root, carefully dried and powdered, in the proportion of an ounce to six fluidounces of strong alcohol. Of this, eight or ten drops may be given three times a day, and gradually increased till its effects become obvious. Few patients, he observes, will bear more than twenty drops. Aconite may be used externally in the form of the strong tincture just referred to, of extract mixed with lard, of a plaster made with the extract, or of *aconitina*. (See *Extractum Aconiti*, *Extractum Aconiti Alcoholicum*, and *Aconitina*.) The tincture may be applied by means of a piece of soft sponge fastened to the end of a stick.

‡ ADEPS. *U. S.*, *Lond.*

Lard.

“The prepared fat of *Sus Scrofa*, free from saline matter.” *U. S.* “*Sus Scrofa. Adeps præparatus.*” *Lond.*

Off. Syn. *AXUNGIA*. Fat of *Sus Scrofa*. *Ed.*; *ADEPS SUILLUS PRÆPARATUS. Dub.*

Axonge, *Graisse*, *Saindoux*, *Fr.*; *Schweineschmalz*, *Germ.*; *Grasso di porco*, *Lardo*, *Ital.*; *Manteca de puerco*, *Lardo*, *Span.*

Lard is the prepared fat of the hog. The *Dublin College* gives a process for its preparation; but, as in this country it is purchased by the druggists already prepared, the introduction of any official directions into our *Pharmacopœia* was deemed superfluous. The adipose matter of the omentum and mesentery, and that which surrounds the kidneys, are usually employed; though the subcutaneous fat is said to afford lard of a firmer consistence. In the crude state it contains membranes and vessels, and is more or less contaminated with blood, from all which it must be freed before it can be fit

for use. For this purpose, the fat, having been deprived as far as possible, by the hand, of membranous matter, is cut into pieces, washed with water till the liquor ceases to be coloured, and then melted, usually with a small portion of water, in a copper or iron vessel, over a slow fire. The heat is continued till all the moisture is evaporated, which may be known by the transparency of the melted fat, and the absence of crepitation when a small portion of it is thrown into the fire. Care should be taken that the heat is not too great, as otherwise the lard might be partially decomposed, acquire a yellow colour, and become acrid. The process is completed by straining the fluid through linen, and pouring it into suitable vessels, in which it concretes upon cooling.

Lard, as offered for sale, often contains common salt, which renders it unfit for pharmaceutic purposes. To free it from this, the Dublin College directs that it be melted with twice its weight of boiling water, the mixture well agitated and set aside to cool, and the fat then separated.

Properties. Lard is white, inodorous, with little taste, of a soft consistence at ordinary temperatures, fusible at about 100° F., insoluble in water, partially soluble in alcohol, more so in ether and the volatile oils, dissolved and decomposed by the stronger acids, and converted into soap by union with the alkalies. When melted, it readily unites with wax and resins. According to Braconnot, it contains, in 100 parts, 62 of *oléin* or the liquid principle of oils, and 38 of *stearin* or the concrete principle. But M. Le Canu has ascertained that the stearin of Braconnot consists of two distinct substances, differing in fusibility and solubility. For the least fusible of these he retains the name of stearin, and to the other applies that of *margarin*, from its resemblance to the principle of the same name found in vegetable oils. Most fats and oils, of animal origin, are composed of these ingredients, upon the relative proportion of which their consistence respectively depends. The liquid and concrete principles may be obtained separate by the action of boiling alcohol, which on cooling deposits the latter, and yields the former upon evaporation. Another method is to compress fat, or oil congealed by cold, between the folds of bibulous paper. The *oléin* is absorbed by the paper, and may be separated by compression under water; the stearin and margarin remain.

Oléin, originally denominated *eläin*, resembles oil in appearance, is colourless when pure, congeals at 20° F., has little odour and a sweetish taste, is insoluble in water but soluble in boiling alcohol, and consists of carbon, oxygen, and hydrogen. The *oléin* of lard has recently been introduced extensively into use for burning in lamps.

Stearin is white, concrete, of a crystalline appearance like spermaceti, pulverizable, fusible at about 143° , soluble in alcohol and boiling ether, insoluble in cold ether and in water, and composed, like the former principle, of carbon, hydrogen, and oxygen. It may be separated from the concrete matter of lard by treating it with cold ether so long as any thing is dissolved. The stearin is left behind, and the ethereal solution yields margarin by evaporation.

The *margarin* of animal fats resembles stearin very closely, differing only in its melting point, which is about 118° , and in being soluble in cold ether. Very good candles are now made out of the concrete constituents of lard.

Exposed to the air, lard absorbs oxygen and becomes rancid. It should, therefore, be kept in well closed vessels, or procured fresh when wanted for use. In the rancid state it is irritating to the skin, and sometimes exercises an injurious reaction on substances mixed with it. Thus, the ointment of

iodide of potassium, which is white when prepared with fresh lard, is said to be more or less yellow when the lard employed is rancid.

Medical Properties and Uses. Lard is emollient, and is occasionally employed by itself in frictions, or in connexion with poultices to preserve their soft consistence; but its chief use is in pharmacy as an ingredient of ointments and cerates. It is frequently added to laxative enemata. W.

The Pharmacopœias have recognised several pharmaceutical strengths of the liquid, which in its pure state is known to the chemist under the name of alcohol. The British Colleges have adopted three strengths of this substance; while the United States Pharmacopœia has admitted only two. The following table presents a view of the names and strengths of the alcohol according to these different authorities; assuming those spirits to be identical, the specific gravities of which approach to equality.

	U. S.	<i>Lond.</i>	<i>Ed.</i>	<i>Dub.</i>
Highest off. strength. }	—	Alcohol. Sp. gr. 0·815.	Alcohol. Sp. gr. 0·794—6.	Alcohol. Sp. gr. 0·810.
Medium do. }	Alcohol. Sp. gr. 0·835.	Spiritus Rectifi- catus. Sp. gr. 0·838.	Spiritus Rectifi- catus. Sp. gr. 0·838.	Spiritus Rectifi- catus. Sp. gr. 0·840.
Lowest do. }	Alcohol Dilutum. Sp. gr. 0·935.	Spiritus Tenuior. Sp. gr. 0·920.	Spiritus Tenuior. Sp. gr. 0·912.	Spiritus Tenuior. Sp. gr. 0·919.

The London College, in their revised Pharmacopœia for 1836, have introduced *brandy*, under the officinal name of *Spiritus Vini Gallici*. As this is an alcoholic liquor, and may be considered as a fourth form of alcohol recognised by that College, its officinal title has been associated with “*Alcohol*,” in forming the heading of this article.

By the table it is perceived that the officinal “Alcohol” of the United States Pharmacopœia is a rectified spirit of the sp. gr. 0·835; while the spirit, under the same officinal name, of the British Colleges is much stronger. It is certainly to be regretted that the same name has been applied to the substance of such different strengths, as it leads to confusion. Our principal object, however, in this article, is to describe the *alcohol* of the United States Pharmacopœia, corresponding to the British *Spiritus Rectificatus*; and we shall introduce incidentally our notice of brandy and of the stronger spirit of the British Colleges, also called *alcohol*. The *Alcohol Dilutum*, and the corresponding preparations of the British Pharma-

copœias, will be considered in their appropriate place, in the second part of this work. (See *Alcohol Dilutum*.)

Alcohol, in the chemical sense, is a peculiar liquid, generated for the most part in vegetable juices and infusions by a peculiar fermentation, called the vinous or alcoholic. The liquids which have undergone it are called vinous liquors, and are of various kinds. Thus the fermented juice of the grape is called wine; of the apple, cider; and the fermented infusion of malt, beer.

With regard to the nature of the liquids susceptible of the vinous fermentation, one general character prevails, however various they may be in other respects; that, namely, of containing sugar in some form or other. It is found further, that after they have undergone the vinous fermentation, the sugar they contained has, either wholly or in part, disappeared, and that the only new products are alcohol which remains in the liquid, and carbonic acid which escapes during the process; and these, when taken together, are found to be equal in weight to the sugar lost. It is hence inferred, that sugar is the subject matter of the changes that occur during the vinous fermentation, and that it is resolved into alcohol and carbonic acid. Additional facts in support of this view, will be adduced under the head of the composition of alcohol.

Sugar, however, will not undergo the vinous fermentation by itself; but requires to be dissolved in water, subjected to the influence of a ferment, and kept at a certain temperature. Accordingly, sugar, water, the presence of a ferment, and the maintenance of an adequate temperature, may be deemed the prerequisites of the vinous fermentation. The water acts by giving fluidity, and the ferment and temperature operate by commencing and maintaining the chemical changes. The precise manner in which the ferment operates in commencing the reaction is not known. Neither has it been certainly ascertained whether it is a peculiar vegetable principle, or whether a number of distinct vegetable substances are capable of acting in a similar way. As a general rule, substances containing nitrogen, such as gluten, albumen, caseous matter, &c., possess the property of inducing the vinous fermentation. The proper temperature ranges from 60° to 90°.

Certain vegetable infusions, as those of potatoes and rice, though consisting almost entirely of starch, are, nevertheless, capable of undergoing the vinous fermentation, and form seeming exceptions to the rule that sugar is the only substance susceptible of this fermentation. The apparent exception is explained by the circumstance, that starch is susceptible of a spontaneous change which converts it into sugar. How this change takes place is not well known, but it is designated by some authors as the *saccharine* fermentation. Thus Kirchoff proved, that if a mixture of gluten from flour, and starch from potatoes, be put into hot water, the starch will be converted into sugar. When, therefore, starch is apparently converted into alcohol by fermentation, it is supposed that during the change it passes through the intermediate state of sugar.

Alcohol, being the product of the vinous fermentation, necessarily exists in all vinous liquors, and may be obtained from them by distillation. Formerly it was supposed that these liquors did not contain alcohol, but were merely capable of furnishing it in consequence of a new arrangement of their ultimate constituents, the result of the heat applied. Brande, however, disproved this idea, by showing that alcohol may be obtained from all vinous liquors without the application of heat, and, therefore, must pre-exist in them. His method consists in precipitating their acid and colouring matter

by subacetate of lead, and separating the water by carbonate of potassa. Gay-Lussac and Donovan have proved the same fact. According to the former, litharge in fine powder is the best agent for precipitating the colouring matter.

In vinous liquors, the alcohol is diluted with abundance of water, and associated with colouring matter, volatile oil, extractive, and various acids and salts. In purifying it we take advantage of its volatility, which enables us to separate it by distillation, combined with some of the principles of the vinous liquor employed, and more or less water. The distilled product of vinous liquors forms the different varieties of ardent spirit of commerce. When obtained from wine, it is called brandy; from fermented molasses, rum; from cider, malted barley, or rye, whisky; from malted barley and rye-meal with hops, and rectified from juniper berries, Holland gin; from malted barley, rye, or potatoes, rectified with turpentine, common gin; and from fermented rice, arrack. These spirits are of different strengths, that is, contain different proportions of alcohol, and have various peculiarities by which they are distinguished by the taste. Their strength is accurately judged of by the specific gravity, which is always less in proportion as their concentration is greater. When they have a sp. gr. of 0.920 they are designated in commerce by the term proof spirit. If lighter than this, they are said to be above proof; if heavier, below proof; and the per centage of water, or of spirit of 0.825, necessary to be added to any sample of spirit to bring it to the standard of proof spirit, indicates the number of degrees the given sample is above or below proof. Thus, if 100 volumes of a spirit require 10 volumes of water to reduce it to proof spirit, it is said to be "10 over proof." On the other hand, if 100 volumes of a spirit require 10 volumes of a spirit of 0.825 to raise it to proof, the sample is said to be "10 under proof."

Proof spirit is still very far from being pure; being a dilute alcohol, containing about half its weight of water, together with a peculiar oil and other foreign matters. It may be further purified and strengthened by redistillation, or *rectification* as it is called. Whisky is the spirit usually employed for this purpose; and from every hundred gallons, between fifty-seven and fifty-eight may be obtained, of the average strength of rectified spirit, (sp. gr. 0.835,) corresponding to the *alcohol* of the U. S. Pharmacopœia, and the *Spiritus Rectificatus* of the British Colleges. When this is once more cautiously distilled, it will be further purified from water, and attain the sp. gr. of about 0.825, which is the lightest spirit which can be obtained by ordinary distillation, and is the pure spirit or alcohol of the British system of excise. It still, however, contains eleven per cent. of water. In the mean while, the spirit, by these repeated distillations, becomes more and more freed from the contaminating oil, called *grain oil*.

If it be desired to obtain alcohol of still greater concentration, it is necessary to avail ourselves of certain substances which have a powerful affinity for water. Of this nature are lime, carbonate of potassa, and chloride of calcium. These, being mixed with the rectified spirit, unite with the water and sink, while the purer spirit floats above, and may be separated by decantation or distillation. By availing themselves of substances of this nature, the British Colleges are enabled to produce their strongest spirit, which they denominate *alcohol*. (See tabular view, page 57.) The following are the processes which they adopt.

ALCOHOL (sp. gr. 0.815), *Lond.*—"Take of rectified spirit, a gallon; chloride of calcium, a pound. Add the chloride of calcium to the spirit, and when it has dissolved, distil seven pints, and five fluidounces."

ALCOHOL (sp. gr. 0.794-6), *Ed.*—"Take of rectified spirit, *one pint*, [Imp. meas.]; lime, *eighteen ounces*. Break down the lime into small fragments: expose the spirit and lime together to a gentle heat in a glass matrass till the lime begins to slake: withdraw the heat till the slaking is finished, preserving the upper part of the matrass cool with damp cloths. Then attach a proper refrigeratory, and with a gradually increasing heat distil off seventeen fluidounces. The density of this alcohol should not exceed 796: if higher, the distillation must have been begun before the slaking of the lime was finished."

ALCOHOL (sp. gr. 0.810), *Dub.*—"Take of rectified spirit, *a gallon*; pearlashes, dried and still hot, *three pounds and a half*; muriate of lime, dried, *a pound*. Add the pearlashes in powder to the spirit, and let the mixture digest in a covered vessel for seven days, shaking it frequently. Draw off the supernatant spirit, and mix with it the muriate of lime. Lastly, distil, with a moderate heat, until the mixture in the retort begins to thicken."

In these processes, the London College uses chloride of calcium, the Edinburgh, lime, and the Dublin, both carbonate of potassa and chloride of calcium, for separating the water. These substances are all well fitted to remove the water, on account of their strong attraction for that liquid. Formerly, the London Pharmacopœia directed the use of carbonate of potassa for this purpose; but in the revision of 1836, the chloride was advantageously substituted, which, on account of its solubility in alcohol, is more powerful than the alkaline salt, as an agent for separating water. By the processes of the London and Dublin Colleges, the rectified spirit is not entirely deprived of water; but by the Edinburgh formula, it is brought at once to its highest strength, when it has a specific gravity between 0.794 and 0.796, and is called *anhydrous* or *absolute alcohol*. The official alcohol of the London and Dublin Colleges may be brought to the same strength, by very carefully and repeatedly distilling it from chloride of calcium.

Soubeiran recommends the following as an easy method for obtaining absolute alcohol abundantly and economically. 1st. Rectify alcohol, marking 86° of the centesimal alcoholmeter of Gay-Lussac (rectified spirit), by distilling it from carbonate of potassa. This operation raises its strength to 94° or 95°. 2d. Raise this alcohol to 97°, by distilling it with fused chloride of calcium, or by digesting it with quicklime, from which it must be afterwards poured off, in the proportion of a pint of the alcohol to 1½ ounces of the chloride, or 2¼ ounces of the lime. 3d. Distil the product of this operation slowly, with quicklime, in the proportion of 3¾ ounces to the pint. The product will be absolute alcohol. The operation may be shortened to two steps, by distilling the alcohol of 94° or 95°, with an excess of quicklime, (7½ ounces to the pint.) In all cases, the alcohol must be digested for two or three days with the lime, before decanting or distilling, at a temperature between 95° and 100° F. Lime will not answer as a substance to be distilled from, unless it be in sufficient excess; for otherwise, towards the end of the distillation, the hydrate of lime formed, will yield up its water to the alcohol, and weaken the distilled product. (*Journ. de Pharm.* xxv. 1. Jan. 1839.)

It thus appears that the process adopted by the Edinburgh College for absolute alcohol, now first introduced into their Pharmacopœia, is substantially the same as that recommended by Soubeiran. Dr. Christison assures us that, on using pure quicklime, with the precautions mentioned in the Edinburgh formula, he has "always obtained from rectified spirit of the density of 0.838, seventeen-twentieths of its volume of alcohol, of density

0.796; and if the first tenth be kept apart, the rest may be obtained so low as 0.7942." A good way for ascertaining when all the water has been removed, is to drop into the liquid a piece of anhydrous baryta, which will remain unchanged if the alcohol be free from water; otherwise it will fall to powder.

Alcohol, though freed from water by the processes indicated, may still be impregnated with a portion of the essential oil called grain oil. This is usually removed by digesting the spirit with charcoal, especially animal charcoal. The same end may be attained on a small scale, by adding a little of the solution of nitrate of silver to the spirit, and exposing it to a bright light. By the action of the oxide of silver on the oil, it is converted into a black powder, and by a new distillation, the spirit is obtained pure. The absolute alcohol of the Edinburgh Pharmacopœia is submitted to this test. Its purity is directed to be such, that, "when mixed with a little solution of nitrate of silver and exposed to bright light, it remains unchanged, or only a very scanty dark precipitate forms."

Properties. Alcohol is a colourless, transparent, volatile liquid, of a penetrating, agreeable odour, and strong burning taste. When free from water of dilution, its sp. gr. is 0.796, or a little under, at the temp. of 60°. Its density progressively increases by dilution, so that its sp. gr. is an index of its strength. When of the sp. gr. 0.820, its boiling point is at 176°; this point being always lower in proportion as the alcohol is stronger. Its specific gravity, as a vapour, is 1.60 compared with air. Absolute alcohol has never been frozen; but Dr. J. K. Mitchell, of this city, succeeded by a cold of 146° below zero, in rendering alcohol of 0.798 viscid, so as to resemble melted wax. In Dr. Mitchell's experiments, alcohol of 0.820 froze readily. On account of the property of alcohol of resisting extreme degrees of cold, without freezing, it is used in thermometers for measuring low degrees of temperature.

Alcohol is inflammable, and burns without smoke or residue, the products being water and carbonic acid. Its flame is of a bluish colour when strong; but yellowish, when weak. It combines with water and ether in all proportions. Its value depends upon the quantity of absolute alcohol which it contains; and as this is greater in proportion as the sp. gr. of any sample is less, it is found convenient to take the density in estimating its purity. This is done by instruments with bulbs and long stems, called hydrometers, which, by being allowed to float in the spirit, sink deeper into it in proportion as it is lighter. Any given hydrometer strength corresponds with some particular specific gravity; and by referring to tables constructed for the purpose, the percentage of absolute alcohol indicated in each case is at once shown. The following table, constructed by Lowitz and improved by Thomson, is of this kind. We have placed in notes, referring to their respective specific gravities in the table, the names of the different officinal spirits, whereby the percentage of absolute alcohol is indicated which they severally contain.

Alcohol is capable of dissolving a great number of substances; as for example, sulphur and phosphorus in small quantity, iodine, ammonia, and potassa, soda and lithia in the caustic state, but not as carbonates. Among vegetable substances, it is a solvent of the organic vegetable alkalies, urea, tannic acid, sugar, mannite, camphor, resins, balsams, volatile oils, and soap. It dissolves the fixed oils sparingly, except castor oil, which is abundantly soluble. It acts on most acids, forming ethers with some, and effecting the solution of others. All deliquescent salts are soluble in alcohol, except carbonate of potassa; while the efflorescent salts, and those either insoluble or sparingly soluble in water, are mostly insoluble in it. It dissolves muriate of ammonia, and most of the chlorides that are readily soluble in water; also some nitrates, but none of the metallic sulphates.

It is capable of combining, in the solid form, with different substances, so as to form definite compounds, which, from their analogy to hydrates, are called *alcoates*.

Composition. Alcohol consists of six eqs. of hydrogen 6, four of carbon 24·48, and two of oxygen 16=46·48; or in volumes, of six volumes of hydrogen, four volumes of the vapour of carbon, and one volume of oxygen. These elements may be viewed as united, so as to form a compound either of one eq. of etherine and two of water ($C_4H_4 + 2HO$), or of one eq. of ether and one of water ($C_4H_5O + HO$). Considered as a compound of etherine and water, it consists in volumes, of one volume of the vapour of etherine,

and two volumes of the vapour of water, condensed into two volumes. *Etherine* is a highly volatile liquid, discovered by Faraday, consisting of four eqs. of carbon, and four of hydrogen (C_4H_4); or of four volumes of the vapour of carbon and four of hydrogen, condensed into one volume of its vapour.

It has already been stated that, in the vinous fermentation, sugar is converted into alcohol and carbonic acid. This conversion is thus explained. The sugar, of whatever kind, is first changed into *glucose* or *grape sugar*. This, at the temperature of 212° , consists of $H_{12}C_{12}O_{12}$, and is resolved by the fermentation into two eqs. of alcohol ($H_{12}C_8O_4$), and four eqs. of carbonic acid (C_4O_8).

Medical Properties, &c. Alcohol is a very powerful diffusible stimulant. It is the intoxicating ingredient in all spirituous and vinous liquors, including under the latter term, porter, ale, and cider, and every liquid in short which has undergone the vinous fermentation. In its pure state it is never used in medicine; but diluted to various degrees, it forms a menstruum for many remedies. In a diluted state, and taken in small quantity, it excites the system, renders the pulse full, communicates additional energy to the muscles, and gives temporary exaltation to the mental faculties. In some states of acute disease, characterized by excessive debility, it is a valuable remedy. In the form of brandy it is frequently given in the sinking stages of typhus with advantage. Other kinds of ardent spirit are occasionally administered, and each is supposed to have its peculiar qualities. Thus, according to Dr. Paris, brandy may be esteemed simply cordial and stomachic; rum, heating and sudorific; and gin and whisky, diuretic. Physicians should be on their guard not to prescribe alcoholic remedies in chronic diseases, whether alone or in the form of tinctures, for fear of begetting intemperate habits in their patients. Externally, alcohol is sometimes applied to produce cold by evaporation, or to stimulate when its evaporation is repressed. A mixture of equal parts of rectified spirit and white of egg is stated by Dr. Christison to be an excellent application in the early stage of excoriation from pressure in protracted diseases. It is to be applied frequently by a fine brush or feather, and renewed as it dries, until an albuminous coating is formed over the excoriated surface.

As an article of daily use, alcoholic liquors produce the most deplorable consequences. Besides the moral degradation which they cause, their habitual use gives rise to dyspepsia, hypochondriasis, visceral obstructions, dropsy, paralysis, and not unfrequently mania.

Alcohol is extensively employed by perfumers and distillers, in making essences and cordials. In the arts it is used to form drying varnishes, and in chemistry, as an important analytic agent. Being a powerful antiseptic, it is very useful in preserving anatomical preparations.

Effects as a Poison. When taken in large quantity, alcohol, in the form of various ardent spirits, produces a true apoplectic state, and occasionally speedy death. The face becomes livid or pale, the respiration stertorous, and the mouth frothy; and sense and feeling are more or less completely lost. Where the danger is imminent, an emetic may be administered, or the stomach pump used. The affusion of cold water is often very useful. As a counter-poison, acetate of ammonia has been asserted to act with advantage. After death, abundant evidence is furnished of the absorption of the alcohol. By Dr. Percy it has been detected by chemical analysis in the brain, and by others in the ventricles.

Pharmaceutic Uses. Alcohol is very extensively employed as a pharmaceutic agent. Either in its rectified state, or diluted with water, it is

used in the formation of all the tinctures, spirits, ethers, and resinous extracts. It is added to the vinegars, some of the medicated waters, and one or more of the decoctions and infusions, to assist in their preservation; and serves as a vehicle or diluent of certain active medicines, as in the *Spiritus Ammoniac*, and *Acidum Sulphuricum Aromaticum*. It is also employed for various incidental purposes connected with its solvent power.

Aletris farinosa. Willd. *Sp. Plant.* ii. 183; Bigelow, *Am. Med. Bot.* iii. 92. This is an indigenous perennial plant, the leaves of which spring immediately from the root, and spread on the ground in the form of a star. Hence have originated the popular names of *star grass*, *blazing star*, and *mealy starwort*, by which it is known in different parts of the country. The leaves are sessile, lanceolate, entire, pointed, very smooth, longitudinally veined, and of unequal size, the largest being about four inches in length. From the midst of them a flower stem rises, one or two feet in height, nearly naked, with remote scales, which sometimes become leaves. It terminates in a slender scattered spike, the flowers of which stand on very short pedicels, and have minute bractes at the base. The calyx is wanting. The corolla is tubular, oblong, divided at the summit into six spreading segments, of a white colour, and presenting, when old, a mealy or rugose appearance on the outside. The plant is found in almost all parts of the United States, growing in fields and about the borders of woods, and flowering in June and July.

Properties. The root, which is the officinal portion, is small, crooked, branched, blackish externally, brown within, and intensely bitter. The bitterness is extracted by alcohol, and the tincture becomes turbid upon the addition of water. The decoction is moderately bitter; but much less so than the tincture. It affords no precipitate with the salts of iron. (*Bigelow.*)

Medical Properties. In small doses the root appears to be simply tonic, and may be employed advantageously for similar purposes with other bitters of the same class. When largely given it produces nausea. The powder may be administered as a tonic in the dose of ten grains. W.

ALLIUM. *Sex. Syst.* Hexandria Monogynia.—*Nat. Ord.* Liliaceæ.

Gen. Ch. Corolla six-parted, spreading. *Spathe* many-flowered. *Umbel* crowded. *Capsule* superior. *Willd.*

This is a very extensive genus, including more than sixty species, most of which are European. Of the nine or ten indigenous in this country, none are employed. Of the European species, several have been used from a very early period, both as food and medicine. Three only are officinal—the *A. sativum*, or garlick; *A. Ceba*, or onion; and *A. Porrum*, or leek. The U. S. Pharmacopœia has adopted only the *A. sativum*, and to this we shall confine our observations in the present place, simply stating that few genera present a greater resemblance in medical and sensible properties among the various species that compose them, than the present.

Allium sativum. Willd. *Sp. Plant*, ii. 68; Woodv. *Med. Bot.* p. 749, t. 256. This is a perennial plant, and like all its congeners, bulbous. The bulbs are numerous, and enclosed in a common membranous covering, from the base of which the fibres that constitute the proper root descend. The stem is simple, and rises about two feet in height. The leaves are long, flat, and grass-like; and sheath the lower half of the stem. At the termination of the stem is a cluster of flowers and bulbs mingled together, and enclosed in a pointed spathe which opens on one side and withers. The flowers are small and white, and make their appearance in July. This species of garlick grows wild in Sicily, Italy, and the south of France; and is cultivated in all civilized countries.

The part employed, as well for culinary purposes as in medicine, is the bulb. The bulbs are dug up with a portion of the stem attached, and, having been dried in the sun, are tied together in bunches, and thus brought to market. They are said to lose by drying nine parts of their weight out of fifteen, with little diminution of their sensible properties. This species of *Allium* is commonly called *English garlick*, to distinguish it from those which grow wild in our fields and meadows.

Properties. Garlick, as found in the shops, is of a shape somewhat spherical, flattened at the bottom, and drawn towards a point at the summit, where a portion of the stem several inches in length projects. It is covered with a white, dry, membranous envelope, consisting of several delicate laminæ, within which the small bulbs are arranged around the stem, having each a distinct coat. These small bulbs, which in common language are called *cloves* of garlick, are usually five or six in number, of an oblong shape, somewhat curved, and in their interior are whitish, moist, and fleshy. They have a disagreeable pungent odour, so peculiar as to have received the name of *alliaceous*. Their taste is bitter and acrid. This smell and taste, though strongest in the bulb, are found to a greater or less extent in all parts of the plant. They depend on an *essential oil* which is very volatile, and may be obtained by distillation, passing over with the first portions of water. It is of a yellow colour, exceedingly pungent odour, and strong acrid taste; is heavier than water; contains sulphur; and when applied to the skin produces much irritation, and sometimes even blisters. Cadet-Gassicourt obtained six drachms of it from 20 lbs. of garlick. Besides this oil, fresh garlick, according to the same chemist, contains in 1406 parts, 520 of mucilage, 37 of albumen, 48 of fibrous matter, and 801 of water. Bouillon-Lagrange mentions among its constituents, sulphur, a saccharine matter, and a small quantity of fecula. The fresh bulbs yield upon pressure nearly a fourth part of juice, which is highly viscid, and so tenacious as to require dilution with water before it can be easily filtered. When dried it serves as a lute for porcelain. It has the medical properties of the bulbs. Water, alcohol, and vinegar extract the virtues of garlick. Boiling, however, if continued for some time, renders it inert.

Medical Properties and Uses. The use of garlick as a medicine and

condiment, ascends to the highest antiquity. When it is taken internally, the active principle is very speedily absorbed, and penetrating throughout the system, becomes sensible in the breath and various secretions. Even externally applied, as for example to the soles of the feet, it imparts its peculiar odour to the breath, urine, and perspiration, and, according to some writers, may be tasted in the mouth. Its effects upon the system are those of a general stimulant. It quickens the circulation, excites the nervous system, promotes expectoration in a debilitated state of the vessels of the lungs, produces diaphoresis or diuresis according as the patient is kept warm or cool, and acts upon the stomach as a tonic and carminative. It is said also to be emmenagogue. Applied to the skin, it is irritant and rubefacient, and moreover exercises, to a greater or less extent, its peculiar influence upon the system, in consequence of its absorption. Moderately employed, it is beneficial in enfeebled digestion and flatulence; and is habitually used as a condiment by many who have no objection to an offensive breath. It has been given with advantage in chronic catarrh, humoral asthma, and other pectoral affections in which the symptoms of inflammation have been subdued, and a feeble condition of the vessels remains. We use it habitually and with great benefit in such affections occurring in children, as well as in the nervous and spasmodic coughs to which this class of patients are peculiarly liable. Some physicians have highly recommended it in old atonic dropsies and calculous disorders; and it has been employed in the treatment of intermittents. It is said also to be an excellent anthelmintic. If taken too largely, or in excited states of the system, it is apt to occasion gastric irritation, flatulence, hemorrhoids, headach, and fever. As a medicine, it is at present more used externally than inwardly. Bruised and applied to the feet, it acts very beneficially as a revulsive in disorders of the head; and is especially useful in the febrile complaints of children, by quieting restlessness and producing sleep. In the same state it is used to resolve indolent tumours. Its juice mixed with oil, or the garlick itself bruised and steeped in spirits, is frequently used as a liniment in infantile convulsions, and other cases of spasmodic or nervous disorder among children. The same application has been made in cases of cutaneous eruption. A clove of garlick, or a few drops of the juice introduced into the ear, are said to prove highly efficacious in atonic deafness; and the bulb, bruised and applied in the shape of a poultice above the pubis, has sometimes restored action to the bladder in cases of retention of urine, from debility of that organ. In the same shape it has been recommended as a resolvent in indolent tumours, and may, perhaps, prove beneficial by stimulating the absorbents.

Garlick may be taken in the form of pill; or the clove may be swallowed either whole, or cut into pieces of a convenient size. Its juice is also frequently administered mixed with sugar. The infusion in milk was at one time highly recommended, and the syrup is officinal. The dose in substance is from a half a drachm to a drachm, or even two drachms of the fresh bulb. That of the juice is half a fluidrachm.

ALLIUM CEPA. Bulbus. *Dub.*

Onion.

Ognon, *Fr.*; Zwiebel-Lauch, *Germ.*; Cipolla, *Ital.*; Cebolla, *Span.*

ALLIUM. See ALLIUM, U. S.

Allium Cepa. Willd. *Sp. Plant.* ii. 80. The onion is a perennial bulbous plant, with a naked scape, swelling towards the base, exceeding the

leaves in length, and terminating in a simple umbel of white flowers. The leaves are hollow, cylindrical, and pointed.

The original country of this species of *Allium* is unknown. The plant has been cultivated from time immemorial, and is now diffused over the whole civilized world. All parts of it have a peculiar pungent odour, but the bulb only is used.

Properties. The bulb is of various size and shape, ovate, spherical, or flattened, composed of concentric fleshy and succulent layers, and covered with dry membranous coats, which are reddish, yellowish, or white, according to the variety. It has, in a high degree, the characteristic odour of the plant, with a sweetish and acrid taste. Fourcroy and Vauquelin obtained from it a white acrid volatile oil holding sulphur in solution, albumen, much uncrystallizable sugar and mucilage, phosphoric acid both free and combined with lime, acetic acid, citrate of lime, and lignin. The expressed juice is susceptible of the vinous fermentation.

Medical Properties and Uses. The onion is stimulant, diuretic, expectorant, and rubefacient. Taken moderately, it increases the appetite and promotes digestion, and is much used as a condiment; but in large quantities it is apt to cause flatulence, gastric uneasiness, and febrile excitement. The juice is occasionally given, made into syrup with sugar, in infantile catarrhs and croup, in the absence of much inflammatory action. It is also recommended in dropsy and calculous disorders. Deprived of its essential oil by boiling, the onion becomes a mild esculent; and it is much more used as food than as medicine. Roasted and split, it is sometimes applied as an emollient cataplasm to suppurating tumours. W.

Aloes.

“The inspissated juice of the leaves of *Aloe spicata*, and other species of *Aloe*.” U.S. “*Aloe spicata. Foliorum succus spissatus.*” Lond.

Off. Syn. ALOE BARBADENSIS. ALOE INDICA. ALOE SOCOTORINA. From undetermined species of *Aloe*. *Ed.*; ALOE HEPATICA, ex *A. vulgari*. ALOE SOCOTORINA, ex *A. spicata*. *Dub.*

Sue d'aloës, Fr.; Aloe, Germ., Ital.; Aloë, Span.; Muesbeber, Arab

Most of the species belonging to the genus *Aloe* are said to yield a bitter juice, which has all the properties of the officinal aloes. It is impossible, from the various and sometimes conflicting accounts of writers, to determine exactly from which of the species the drug is in all instances actually derived. The *Aloe spicata*, however, is generally acknowledged to be an abundant source of it; and the *Aloe vulgaris* and *Aloe Socotrina* are usually ranked among the medicinal species. In Lindley's *Flora Medica*, *A. purpurascens*,* *A. arborescens*,† *A. Commelyni*, and *A. multiformis*, all natives of the Cape of Good Hope, are enumerated as yielding aloes; and others are, without doubt, occasionally resorted to. The U.S. Pharmacopœia and that of London at present recognise particularly only the *Aloe spicata*. We shall confine ourselves to a description of the three following species, which probably yield most of the aloes of commerce.

Aloe. Sex. Syst. Hexandria Monogynia.—*Nat. Ord.* Liliaceæ.

Gen. Ch. Corolla erect, mouth spreading, bottom nectariferous. Filaments inserted into the receptacle. *Willd.*

* Curtis's Botanical Magazine, pl. 1474.

† De Candolle, *Plantes Grasses*, fig. 38. Curtis's Bot. Mag. pl. 1306.

Aloe spicata. Willd. *Sp. Plant.* ii. 185. This species of aloes was first described by Thunberg. The stem is round, three or four feet high, about four inches in diameter, and leafy at the summit. The leaves are spreading, subverticillate, about two feet long, broad at the base, gradually narrowing to the point, channeled or grooved upon their upper surface, and with remote teeth upon their edges. The flowers are bell-shaped, and spread horizontally in very close spikes. They contain a large quantity of purple honey juice. Beneath each flower is a broad, ovate, acute bracte, of a white colour with three green streaks, and nearly as long as the corolla. Of the six petals, the three inner are ovate, obtuse, white, with three green lines, and broader than the outer, which otherwise resemble them. The stamens are much longer than the corolla. The spiked aloe is a native of Southern Africa, growing near the Cape of Good Hope, and, like all the other species of this genus, preferring a sandy soil. In some districts of the colony it is found in great abundance, particularly at Zwelendani, near Mossel bay, where it almost covers the surface of the country. Much of the Cape aloes is said to be derived from this species.

A. Socotrina. Lamarck. *Encycl.*, i. 85; De Cand. *Plantes Grasses*, fig. 85; Curtis' *Bot. Mag. pl.* 472.—*A. vera*. Miller, *Dict.*, ed. 8, no. 55. The stem of this species is erect, a foot and a half or more in height, woody, and leafless below, where it is very rough from the remains of former leaves. At top it is embraced by green, sword-shaped, ascending leaves, somewhat concave on their upper surface, convex beneath, curved inward at the point, with numerous small white serratures at their edges. The flowers, which are in a cylindrical, simple raceme, are scarlet near the base, pale in the centre, and greenish at the summit, and have unequal stamens, of which three are longer than the corolla. The plant received its name from the island of Socotra, of which it is said to be a native; and it is supposed to be the source of the Socotrine aloes.

A. vulgaris. Lamarck, *Encycl.*, i. 86; De Cand. *Plantes Grasses*, fig. 27. This species has a very short woody stem, and lanceolate embracing leaves, which are first spreading, then ascending, of a glaucous-green colour somewhat mottled with darker spots, flat on the upper surface, convex beneath, and armed with hard reddish spines, distant from each other, and perpendicular to the margin. The flower-stem is axillary, of a glaucous-reddish colour, and branched, with a cylindrical-ovate spike of yellow flowers, which are at first erect, then spreading, and finally pendulous, and do not exceed the stamens in length. *A. vulgaris* is a native of south-eastern Europe and the north of Africa, is cultivated in Italy, Sicily, Malta, and especially in the W. Indies, where it contributes largely to furnish the Barbadoes aloes.

The proper aloetic juice exists in longitudinal vessels beneath the epidermis of the leaves, and readily flows out when these are cut transversely. The liquid obtained by expression from the parenchyma is mucilaginous, and possessed of little medicinal virtue. The quality of the drug depends much upon the mode of preparing it. The finest kind is that obtained by exudation and subsequent inspissation in the sun. Most of the better sorts, however, are prepared by artificially heating the juice which has spontaneously exuded from the cut leaves. The chief disadvantage of this process is the conversion of a portion of the soluble active principle into an insoluble and comparatively inert substance, through the influence of an elevated temperature. The plan of bruising and expressing the leaves, and boiling down the resulting liquor, yields a much inferior product; as a large portion of it must be derived from the mucilaginous

juice of the parenchyma. The worst plan of all is to boil the leaves themselves in water, and to evaporate the decoction. The quality of the drug is also affected by the careless or fraudulent mixture of foreign matters with the juice, and the unskilful management of the inspissation.

Commercial History and Varieties. Four chief varieties of aloes are known in commerce, that of the Cape of Good Hope, the Socotrine, the Hepatic, and the Barbadoes, of which the first two are most used in this country.

1. **CAPE ALOES**, which is by far the most abundant, and, by its extraordinary cheapness and excellent qualities, promises to supersede the other varieties, has been imported chiefly if not exclusively from Great Britain; as no direct trade has till recently been carried on between the U. States and the Cape of Good Hope. It is collected by the Hottentots and Dutch boors, indiscriminately from the *A. spicata* and other species, which grow wild in great abundance. The process is very simple. According to the account of Hallbeck, a Moravian Missionary who resided at the Cape, a hole is made in the ground, in which a sheep skin is spread with the smooth side upward. The leaves are then cut off near the stem and arranged around the hole, so that the juice which runs out may be received into the skin. The juice flows most freely in hot weather. (*Un. Breth. Mission. Intelligencer, N. Y., vi. 436.*) When a sufficient quantity of the liquor has been collected, it is inspissated by artificial heat in iron cauldrons, care being taken to prevent its burning by constant stirring. When sufficiently concentrated, it is poured into boxes or skins, where it concretes upon cooling. The finest kind is collected at the Missionary Institution at Bethelsdorp, and hence called *Bethelsdorp aloes*. Its superiority is owing exclusively to the greater care observed in conducting the evaporation, and in avoiding the intermixture of earth, stones, and other impurities. (*Dunsterville, in Pereira's Mat. Med.*)

Cape aloes has sometimes been confounded with the Socotrine, from which, however, it differs very considerably in appearance and sensible properties. By the German writers it is called *shining aloes*. When freshly broken, it has a very dark olive or greenish colour approaching to black, presents a smooth bright almost glassy surface, and if held up to the light appears translucent at its edges. The small fragments also are semi-transparent, and have a tinge of yellow or red mixed with the deep olive of the opaque mass. The same tinge is sometimes observable in the larger pieces. The powder is of a fine greenish-yellow colour, and being generally more or less sprinkled over the surface of the pieces as they are kept in the shops, gives them a somewhat yellowish appearance. The odour is strong and disagreeable, but not nauseous. It has not the slightest mixture of the aromatic. Cape aloes, when perfectly hard, is very brittle, and readily reduced to powder; but in very hot weather, it is apt to become somewhat soft and tenacious, and the interior of the pieces is occasionally more or less so even in winter. It is usually imported in casks or boxes. Dr. Pereira says that a variety of aloes is sometimes imported into England from the Cape, of a reddish-brown colour like hepatic aloes.

2. **SOCOTRINE ALOES.** The genuine Socotrine aloes is produced in the Island of Socotra, which lies in the Straits of Babelmandel, about forty leagues to the east of Cape Guardafui; but we are told by Ainslie, that the greater part of what is sold under that name is prepared in the kingdom of Melinda, upon the eastern coast of Africa; and Wellsted states that the aloes of the neighbouring parts of Arabia is the same as that of Socotra. It is probable that the commerce in this variety of aloes is carried on chiefly by

the maritime Arabs, who convey it either to India, or up the Red Sea by the same channel through which it reached Europe before the discovery of the southern passage into the Indian Ocean. The species of Aloe which yields it is not certainly known. Ainslie says that it is evidently from the same species with the Cape aloes; but he does not give his reasons for the opinion; and the external character of the two varieties is so different, that we cannot but hesitate in admitting their identity of origin. We have been able to discover no good reason for depriving the *A. Socotrina* of the honour formerly conceded to it, of producing this highly valued variety of aloes. According to Wellsted, the plant grows on the sides and summits of mountains, from five hundred to three thousand feet above the level of the plains. It is found in all parts of the island, but most abundantly on the western portion, where the surface is thickly covered with it for miles. It appears to thrive best in parched and barren places. Much less of the drug is collected than formerly, and in the year 1833 only two tons were exported. The whole produce was formerly monopolized by the Arabian Sultan of Kisseen, who still claims sovereignty over the island. But at present the business of collecting the drug is entirely free to the inhabitants. The leaves are plucked at any period of the year, and are placed in skins into which the juice is allowed to exude. In what way the inspissation is effected we are not informed. The aloes is exported in skins. Its quality differs much according to the care taken in its preparation. The price varies in Muscat from two to four shillings a pound. (*Wellsted's Voyage to the coast of Arabia and Tour in the Island of Socotra.*) A portion ascends the Red Sea, and through Egypt reaches the ports of Smyrna and Malta, whence it is sent to London. Another portion is carried to Bombay, and thence transmitted to various parts of the world. The little that reaches this country either comes by special order from London, or is brought by our India traders. We have known of two arrivals directly into the United States from the Island of Socotra, and have in our possession parcels of aloes brought by both. They are identical in character, and correspond exactly with the following description.

Socotrine aloes is in pieces of a yellowish or reddish-brown colour, wholly different from that of the former variety. Sometimes the colour is very light, especially in the fresh and not fully hardened parcels; sometimes it is a deep brownish-red like that of garnets. It is rendered much darker by exposure to the air; and the interior of the masses is consequently much lighter coloured than the exterior. Its surface is somewhat glossy, and its fracture smooth and conchoidal, with sharp and semi-transparent edges. The colour of its powder is a bright golden yellow. It has a peculiar, not unpleasant odour, and a taste, which, though bitter and disagreeable, is accompanied with an aromatic flavour. Though hard and pulverulent in cool weather, it is somewhat tenacious in summer, and softens by the heat of the hand.

Under the name of Socotrine aloes are occasionally to be met with in the market, small parcels beautifully semi-transparent, shining, and of a yellowish, reddish, or brownish-red colour. These, however, are very rare, and do not deserve to be considered as a distinct variety. They are probably portions of the juice carefully inspissated in the sun, and may accompany the packages brought from any of the commercial sources of aloes.

When in mass, as imported from the East, Socotrine aloes is soft and plastic, and of a very light yellowish-brown colour in the interior. It becomes hard and brittle when broken into pieces; and the London dealers hasten the result by exposing it to a very gentle heat, so as to evaporate the

moisture. Pereira tells us that impure and dirty pieces of the drug are melted and strained, and that the skins from which the best portions have been removed are washed with water, which is then evaporated. No inconsiderable portion of the Socotrine aloes received from London has probably undergone such processes.

Much of the aloes sold as Socotrine, has never seen the Island of Socotra, nor even the Indian seas. It has been customary to affix this title as a mark of superior value to those portions of the drug, from whatever source they may have been derived, which have been prepared with unusual care, and are supposed to be of the best quality. Thus, both in Spain and the West Indies, the juice which is obtained without expression, and inspissated in the sun without artificial heat, has been called Socotrine aloes; and is probably little inferior to the genuine drug.

The Socotrine aloes has been very long known under this name, and in former times held the same superiority in the estimation of the profession, which it still to a certain degree retains.

3. HEPATIC ALOES. Much confusion and uncertainty have prevailed in relation to this kind of aloes. The name was originally applied to a product from the East Indies of a reddish-brown or liver colour, which gave origin to the designation. From a supposed resemblance between this and the aloes from the West Indies, the name was very commonly applied also to the latter variety, and was also extended to portions of the drug collected in Spain and other parts of the south of Europe. But the West India aloes is decidedly different from any now brought from the East, and deserves the rank of a distinct variety, with the name of Barbadoes aloes. In this country we seldom meet with aloes bearing the name of the hepatic, although much that is sold as Socotrine probably deserves it. In the drug commerce of London, it is still recognised as a distinct variety. It is imported into England chiefly from Bombay; but, according to Ainslie, is not produced in Hindostan, being taken thither from Yemen in Arabia. It is probably obtained from the same plant or plants which yield the Socotrine, but prepared with less care, or by a somewhat different process. In relation to the Socotrine and hepatic aloes, we should probably not be far wrong in considering the former as embracing the finest, and the latter the inferior parcels of the same variety; and it is in fact stated that they sometimes come together, a large mass of the hepatic being crossed by a vein of the Socotrine. They are both embraced by the Edinburgh College under the title of *ALOE INDICA*—an improper designation; as the aloes which is produced in India is altogether inferior, and is seldom or never exported from that region. The variety which the Edinburgh College designates as Socotrine aloes, and defines to be “in thin pieces translucent and garnet-red, almost entirely soluble in spirit of the strength of sherry,” has little claim to the title, being of unknown origin, very rare, and wholly unlike the drug usually brought from Socotra.

Hepatic aloes is of a reddish-brown colour, but is darker and less glossy than the Socotrine. Its odour is somewhat like that of the Socotrine, but less agreeable, and is wholly different from that of Cape aloes. The taste is nauseous, and intensely bitter. The fracture is not so smooth, nor the edges so sharp and transparent as in either of the first mentioned varieties. It softens in the hand, and becomes adhesive. The powder is of a dull yellow colour.

4. BARBADOES ALOES. This is the name by which the aloes produced in the West Indies is now generally designated. The aloes plants are largely cultivated in the poorer soils of Jamaica and Barbadoes, especially of the

latter island. The species from which most of the drug is procured is the *A. vulgaris*; but the *A. Socotrina*, *A. purpurascens*, and *A. arborescens*, are also said to be cultivated. The process employed appears to be somewhat different in different places, or at least as described by different authors. A fine kind was formerly prepared by the spontaneous inspissation of the juice, placed in bladders or shallow vessels, and exposed to the sun. The common Barbadoes aloes, however, is now made, either by boiling the juice to a proper consistence, or by first forming a decoction of the leaves, chopped and suspended in water in nets or baskets, and then evaporating the decoction. In either case, when the liquor has attained such a consistence that it will harden on cooling, it is poured into calabashes and allowed to concrete. It is imported into England in gourds weighing from 60 to 70 pounds or even more. In consequence of the great demand for it in veterinary practice, it commands a high price in Great Britain, and very little is consumed in the United States.

The colour of Barbadoes aloes is not uniform. Sometimes it is dark brown or almost black, sometimes of a reddish-brown or liver colour, and again of some intermediate shade. It has usually a dull fracture, and is almost perfectly opaque even at the edges, and in thin layers. It is also distinguishable by its odour, which is very disagreeable and even nauseous. The powder is of a dull olive-yellow colour.

Besides these varieties of aloes, others are mentioned by authors. A very inferior kind, supposed to consist of the dregs of the juice which furnished the better sorts, almost black, quite opaque, hard, of a rough fracture and very fetid odour, and full of various impurities, was formerly sold under the name of *caballine*, *fetid*, or *horse aloes*. It was used exclusively for horses; but, in consequence of the cheapness of better kinds, has been banished from veterinary practice, and is not now found in the market. Aloes has recently been imported from Muscat, and a considerable quantity came over in the vessel sent by the Sultan to the United States. Some of a similar origin has been called *Mocha aloes* in London; but it is nothing more than an inferior sort of hepatic. Several inferior kinds produced in different parts of Hindostan have been described by Pereira with the name of *India aloes*; but they are not brought, unless accidentally, into the markets of Europe or this country.

General Properties. The odour of aloes is different in the different varieties. The taste is in all of them intensely bitter and very tenacious. The colour and other sensible properties have already been sufficiently described. Several distinguished chemists have investigated the nature and composition of aloes. The opinion at one time entertained, that it was a gum-resin, has been abandoned since the experiments of Braconnot, who found it to consist of a bitter principle, soluble in water and in alcohol of 38° B., which he considered peculiar and named *resino-amer*; and of another substance, in much smaller proportion, inodorous and nearly tasteless, very soluble in alcohol, and scarcely soluble in boiling water, which he designated by the name of *flea-coloured principle*. These results have been essentially confirmed by the experiments of Trommsdorff, Bouillon-Lagrange, and Vogel, who consider the former substance as extractive matter, and the latter as having the chief characters of resin. Besides these principles, Trommsdorff discovered in a variety of hepatic aloes, a proportion of insoluble matter which he considered as albumen; and Bouillon-Lagrange and Vogel found that Socotrine aloes yields, by distillation, a small quantity of volatile oil, which they could not obtain from the hepatic. The proportions of the ingredients vary greatly in the different varieties of the drug;

and the probability is, that scarcely any two specimens would afford precisely the same results. Braconnot found about 73 per cent. of the *bitter principle*, and 26 of the *flea-coloured principle*. Trommsdorff obtained from Socotrine aloes about 75 parts of extractive, and 25 of resin; and from the hepatic, 81·25 of extractive, 6·25 of resin, and 12·50 of albumen, in the hundred parts. The former variety, according to Bouillon-Lagrange and Vogel, contains 68 per cent. of extractive and 32 of resin; the latter 52 of extractive, 42 of resin, and 6 of the albuminous matter of Trommsdorff. We are not aware that any analysis has been published of the Cape aloes as a distinct variety.

Berzelius considers the resin of Trommsdorff and others, to belong to that form of matter which he calls *apothême*, (See *Extracts*,) and which is nothing more than extractive, altered by the action of the air. It may be obtained separate, by treating aloes with water, and digesting the undissolved portion with oxide of lead, which unites with the apothême forming an insoluble compound, and leaves a portion of unaltered extractive, which had adhered to it, dissolved in the water. The oxide of lead may be separated by nitric acid very much diluted; and the apothême remains in the form of a brown powder, insoluble in cold water, very slightly soluble in boiling water, to which it imparts a yellowish-brown colour, soluble in alcohol, ether, and alkaline solutions, and burning like tinder without flame and without being melted. According to the same author, the *bitter extractive* which constitutes the remainder of the aloes, and for which the name of *aloesin* has been proposed, may be obtained by treating the watery infusion of the drug with oxide of lead, to separate a portion of apothême which adheres to it, and evaporating the liquor. Thus procured, it is a yellowish, translucent, gum-like substance, fusible by a gentle heat, of a bitter taste, soluble in ordinary alcohol, but insoluble in that fluid when anhydrous, and in ether. Chlorine produces with its solution a precipitate analogous to apothême. Cold sulphuric acid dissolves without changing it. Nitric acid dissolves it, producing a greenish colour. Its solution is rendered brighter by acids, which occasion a slight precipitate, and dark red by the alkalies and the salts of iron. Acetate of lead, tartar emetic, perchloride of tin, and the salts of manganese, zinc, and copper, do not disturb the solution; the protochloride of tin, and the nitrates of mercury and silver occasion precipitates. It is probably the active portion of the drug.

Aloes yields its active matter to cold water, and when good is almost wholly dissolved by boiling water; but the resinous portion, or apothême of Berzelius, is deposited as the solution cools. It is also soluble in alcohol, rectified or diluted. Long boiling impairs its purgative properties by converting the extractive into insoluble apothême. The alkalies, their carbonates, and soap, alter in some measure its chemical nature, and render it of easier solution. It is inflammable, swelling up and decrepitating when it burns, and giving out a thick smoke which has the odour of the drug.

Those substances only are incompatible with aloes, which alter or precipitate the bitter extractive (aloesin), as the insoluble portion is without action upon the system. Its aqueous solution keeps a long time, even for several months, without exhibiting mouldiness or putrescency; but it becomes ropy, and acquires the character, which it did not previously possess, of affording an abundant precipitate with the infusion of galls.

Medical Properties and Uses. Aloes was known to the ancients. It is mentioned in the works of Dioscorides and Celsus, the former of whom speaks of two kinds. The varieties are similar in their mode of action.

They are all cathartic, operating very slowly but certainly, and having a peculiar affinity for the large intestines. Their action, moreover, appears to be directed rather to the muscular coat than to the exhalent vessels; and the discharges which they produce, are therefore seldom very thin or watery. In a full dose they quicken the circulation, and produce general warmth. When frequently repeated, they are apt to irritate the rectum, giving rise, in some instances, to hemorrhoids, and aggravating them when already existing. Aloes has also a decided tendency to the uterine system. Its emmenagogue effect, which is often very considerable, is generally attributed to a sympathetic extension of irritation from the rectum to the uterus; but we can see no reason why the medicine should not act specifically upon this organ; and its influence in promoting menstruation is by no means confined to cases in which its action upon the neighbouring intestine is most conspicuous. A peculiarity in the action of this cathartic is, that an increase of the quantity administered beyond the medium dose, is not attended by a corresponding increase of effect. Its tendency to irritate the rectum may be obviated, in some measure, by combining it with soap or an alkaline carbonate; but it does not follow, as supposed by some, that this modification of its operation is the result of increased solubility; for aloes given in a liquid state produces the same effect as when taken in pill or powder, except that it acts somewhat more speedily. Besides, when externally applied to a blistered surface, it operates exactly in the same manner as when internally administered; thus proving that its peculiarities are not dependent upon the particular form in which it may be given, but on specific tendencies to particular parts.* With its other powers, aloes combines the property of slightly stimulating the stomach. It is, therefore, in minute doses, an excellent remedy in habitual costiveness, attended with torpor of the digestive organs. From its special direction to the rectum, it has been found peculiarly useful in the treatment of ascarides. In amenorrhœa it is perhaps more frequently employed than any other remedy, entering into almost all the numerous empirical preparations which are habitually resorted to by females in this complaint, and enjoying a no less favourable reputation in regular practice. It is, moreover, frequently given in combination with more irritating cathartics, in order to regulate their liability to excessive action. In the treatment of amenorrhœa, it is said to be peculiarly efficacious when given in the form of enema about the period when the menses should appear. Aloes is contra-indicated by the existence of hemorrhoids, and is obviously unsuitable, unless modified by combination, to the treatment of inflammatory diseases.

The medium dose is 10 grains; but as a laxative it will often operate in the quantity of 2 or 3 grains; and when a decided impression is required, the dose may be augmented to 20 grains. In consequence of its excessively bitter and somewhat nauseous taste, it is most conveniently administered in the shape of pill.†

* See a paper on Endermic Medication, by Dr. Gerhard, in the North Am. Med. and Surg. Journ. vol. x. p. 155.

† Dr. Paris enumerates the following empirical preparations, containing aloes as a leading ingredient:—ANDERSON'S PILLS, consisting of aloes, jalap, and oil of aniseed; HOOPER'S PILLS, of aloes, myrrh, sulphate of iron, canella, and ivory black; DIXON'S ANTIBILIOUS PILLS, of aloes, scammony, rhubarb, and tartarized antimony; SPEEDIMAN'S PILLS, of aloes, myrrh, rhubarb, extract of chamomile, and ess. oil of chamom.; DINNER PILLS, of aloes, mastich, red roses, and syrup of wormwood; FOTHERGILL'S PILLS, of aloes, scammony, colocynth, and oxide of antimony; PETER'S PILLS, of aloes, jalap, scammony, gamboge, and calomel; and RADCLIFF'S ELIXIR, of aloes, cinnamon, zedoary, rhubarb, cochineal, syrup of buckthorn, and spirit and water as the solvent; to which may be added, LEE'S WINDHAM PILLS, consisting of gamboge, aloes, soap, and nitrate of potassa, and LEE'S NEW-LONDON PILLS, of aloes, scammony, gamboge, calomel, jalap, soap, and syrup of buckthorn.

Gen. Ch. Calyx double, the exterior six or nine-cleft. Capsules numerous, one-seeded. *Willd.*

Althæa Officinalis. Willd. *Sp. Plant.* iii. 770.; Woodv. *Med. Bot.* p. 552. t. 198. The marshmallow is an herbaceous perennial, with a perpendicular branching root, and erect woolly stems, from two to four feet or more in height, branched and leafy towards the summit. The leaves are alternate, petiolate, nearly cordate on the lower part of the stem, oblong-ovate and obscurely three-lobed above, somewhat angular, irregularly serrate, pointed, and covered on both sides with a soft down. The flowers are terminal and axillary, with short peduncles, each bearing one, two, or three flowers. The corolla has five spreading, obcordate petals, of a pale purplish colour. The fruit consists of numerous capsules united in a compact circular form, each containing a single seed. The plant grows throughout Europe, inhabiting salt marshes, the banks of rivers, and other moist places. It is found also in this country on the borders of salt marshes. In some parts of the Continent of Europe, it is largely cultivated for medical use. The whole plant abounds in mucilage. Both the leaves and root are officinal, but the latter only is employed to any extent in this country. The flowers are sometimes to be found in the shops, but are scarcely used.

The roots should be collected in autumn from plants at least two years old. They are cylindrical, branched, as thick as the finger or thicker, from a foot to a foot and a half long, externally of a yellowish colour which becomes grayish by drying, within white and fleshy. They are usually prepared for the market by removing the epidermis. Our shops are supplied chiefly if not exclusively from Europe.

Properties. Marshmallow root comes to us in pieces three or four inches or more in length, usually not so thick as the finger, generally round, but sometimes split, white externally and downy from the mode in which the epidermis is removed, light and easily broken with a short somewhat fibrous fracture, of a peculiar faint smell, and a mild mucilaginous sweetish taste. Those pieces are to be preferred which are plump and but slightly fibrous. The root contains a large proportion of mucilage besides starch and saccharine matter, which it yields readily to boiling water. The mucilage, without

the starch, is extracted by cold water, which thus becomes ropy. A principle was discovered in the root by M. Bacon, which he supposed to be peculiar to the marshmallow, but which has been ascertained to be identical with the *asparagin* of Robiquet. MM. Boutron-Charlard and Pelouze found it to belong to that class of organic principles, which are convertible by the agency of strong acids, of potassa or soda, or even of water alone at a high temperature, into ammonia and peculiar acids, and which are designated by the termination *amide*. Thus asparagin, which must now be called *asparamide*, is converted into ammonia and *asparmic*, or, as it was formerly named, *aspartic acid*; and one atom of the resulting asparamate of ammonia is equivalent to one atom of asparamide and one of water. It is found in various other plants besides the marshmallow, as in the shoots of asparagus, in all the varieties of the potato, and in the roots of the comfrey and liquorice plant. (*Journ. de Pharm.* xix. 208.) Asparamide has no therapeutical value. Marshmallow is said to become somewhat acid by decoction. Those pieces should be rejected which are woody, discoloured, mouldy, of a sour or musty smell, or a sourish taste.

The roots of other *Malvaceæ* are sometimes substituted without disadvantage, as they possess similar properties. Such are those of the *Althæa rosea* or *hollyhock*, and the *Malva Alcea*.

The leaves, which are recognised by the British Colleges, are without smell, and of a mucilaginous taste, and are used for the same purposes as the root.

Medical Properties and Uses. The virtues of marshmallow are exclusively those of a demulcent. The decoction of the root is much used in Europe in irritation and inflammation of the mucous membranes. The roots themselves, boiled and bruised, are sometimes employed as a poultice. The leaves are applied to similar uses. In France, the powdered root is much used in the preparation of pills and electuaries.

ALUMEN. *U.S., Lond., Ed., Dub.*

Alum.

“Sulphate of alumina and potassa.” *U. S.*

Alun, Fr., Dan., Swed.; Alaun. Germ.; Allume, Ital.; Alumbre, Span.

The officinal alum is a double salt, consisting of the sulphate of alumina, united with the sulphate of potassa. It is included in the *Materia Medica* of the United States and British Pharmacopœias, as an article to be procured from the wholesale manufacturer.

Alum is manufactured occasionally from earths which contain it ready formed, but most generally from minerals which, embracing most or all of its constituents, are called *alum ores*. The principal alum ores are the *alum stone*, which is a native mixture of subsulphate of alumina and sulphate of potassa, found in large quantities at Tolfa and Piombino in Italy, and certain natural mixtures of sulphuret of iron with clay and carbonaceous matter, called *aluminous schist* or *alum-slate*.

It is particularly at the Solfaterra and other places in the kingdom of Naples, that alum is extracted from earths which contain it ready formed. The ground being of volcanic origin, and having a temperature of about 104°, an efflorescence of pure alum is formed upon its surface. This is collected and lixiviated, and the solution made to crystallize by slow evaporation in leaden vessels sunk in the ground.

The alum stone is manufactured into alum by calcination, and subsequent exposure to the air for three months; the mineral being frequently sprinkled with water, in order that it may be brought to the state of a soft mass. This is lixiviated, and the solution obtained crystallized by evaporation. The alum stone may be considered as consisting of alum, united with a certain quantity of the hydrate of alumina. This latter, by the calcination, loses its water, and becomes incapable of remaining united with the alum of the mineral, which is consequently set free. Alum of the greatest purity is obtained from this ore.

Aluminous schist, when compact, is first exposed to the air for a month. It is then stratified with wood, which is set on fire. The combustion which ensues is slow and protracted. The sulphur is in part converted into sulphuric acid, which unites with the alumina; and the sulphate of alumina thus formed generates a portion of alum with the potassa derived from the ashes of the wood. The iron, in the mean time, is almost wholly converted into sesquioxide, and thus becomes insoluble. The matter is lixiviated, and the solution crystallized into alum by evaporation. The mother-waters, containing sulphate of alumina, are then drawn off, and made to yield a fresh portion of alum by the addition of sulphate of potassa, or chloride of potassium.

When the aluminous schist is easily disintegrated, it is not subjected to combustion, but merely placed in heaps, and occasionally sprinkled with water. The sulphuret of iron gradually absorbs oxygen and passes into the sulphate of the protoxide, which effloresces on the surface of the heap. Part of the sulphuric acid formed unites with the alumina; so that, after the chemical changes are completed, the heap contains both the sulphate of iron and the sulphate of alumina. At the end of about a year, the matter is lixiviated, and the solution of the two sulphates obtained is concentrated to the proper degree in leaden boilers. The sulphate of iron crystallizes, while the sulphate of alumina, being a deliquescent salt, remains in the mother-waters. These are drawn off, and treated with sulphate of potassa in powder, heat being at the same time applied. They are then allowed to cool, that the alum may crystallize. The crystals are then separated from the solution, and purified by a second solution and crystallization. They are next added to boiling water to full saturation, and the solution is transferred to a cask, where, on cooling, nearly the whole concretes into a crystalline mass. The cask is then taken to pieces, and the salt, having been broken up, is packed in barrels for the purposes of commerce. This process is generally followed for manufacturing alum, being employed in France, Great Britain, and the United States.

Alum is sometimes manufactured by the direct combination of its constituents. With this view, clays are selected as free from iron and carbonate of lime as possible, and calcined to sesquioxidize the iron and render them more easily pulverizable; after which they are dissolved, by the assistance of heat, in weak sulphuric acid. The sulphate of alumina thus generated, is next crystallized into alum by the addition of sulphate of potassa in the usual manner.

Besides the officinal alum, which is sometimes called *potassa-alum*, there are several varieties of this salt, in which the potassa is replaced by some other base, as, for example, ammonia or soda. *Ammoniacal alum*, or the sulphate of alumina and ammonia, is sometimes manufactured in France, where it is formed by adding putrid urine to a solution of the sulphate of alumina. In Great Britain it is sometimes made by adding sulphate of ammonia from gas liquor to the sulphate of alumina. Scotch alum, made

near Paisley, generally contains both potassa and ammonia. Ammoniacal alum resembles so exactly the potassa-alum, that it is impossible by simple inspection to distinguish them; and in composition it is perfectly analogous to the potassa salt. It may, however, be distinguished by subjecting it to a strong calcining heat, after which alumina will be found as the sole residue; or by rubbing it up with potassa or lime and a little water, when the smell of ammonia will be perceived.

Properties. Alum is a white, slightly efflorescent salt, crystallized in regular octohedrons, and possessing a sweetish, astringent taste. It dissolves in between fourteen and fifteen times its weight of cold, and three-fourths of its weight of boiling water. Its solution is precipitated by ammonia and potassa, which throw down the alumina as a gelatinous hydrate, free from colour, if the alum be pure. Its sp. gr. is 1.71. It reddens litmus, but changes the blue tinctures of the petals of plants, green. It cannot, therefore, be properly said to contain an excess of acid. When heated a little above 212° , it undergoes the aqueous fusion; and if the heat be continued, it loses its water, swells up, becomes a white, opaque, porous mass, and is converted into the official preparation, called *dried alum*. (See *Alumen Exsiccatum*.) Exposed to a red heat, it gives off oxygen, together with sulphurous and anhydrous sulphuric acids; and the residue consists of alumina and sulphate of potassa. When calcined with finely divided charcoal, it forms a spontaneously inflammable substance, called *Homburg's pyrophorus*, which consists of a mixture of sulphuret of potassium, alumina, and charcoal.

Several varieties of alum are known in commerce. *Roche alum*, so called from its having come originally from Roccha in Syria, is a sort which occurs in fragments, about the size of an almond, and presenting a pale rose colour, which is given to it, according to Dr. Pereira, by bole or rose-pink. *Roman alum* also occurs in small fragments, covered with a rose-coloured efflorescence, derived from a slight covering of oxide of iron.

All the alums of commerce contain more or less sulphate of iron, varying from five to seven parts in the thousand. Roman alum is among the purest varieties, and is, therefore, much esteemed. The iron is readily detected by adding to a solution of the suspected alum, a few drops of the ferrocyanuret of potassium, which will cause a greenish-blue tint, if iron be present. It may be detected also by precipitating the alumina with a solution of potassa, and afterwards adding the alkali in excess. This will redissolve the alumina, but any iron which may have been precipitated with it, will be left in the state of sesquioxide. The quantity of iron usually present, though small, is injurious to the alum when used in dyeing. It may, however, be purified, either by dissolving it in the smallest quantity of boiling water, and stirring the solution as it cools, or by repeated solutions and crystallizations.

Incompatibles. Alum is incompatible with the alkalies and their carbonates, lime and lime-water, magnesia and its carbonate, tartrate of potassa, and acetate of lead.

Composition. Alum was regarded as a sulphate of alumina, until it was proved by Descroizilles, Vauquelin, and Chaptal to contain sulphate of potassa, sulphate of ammonia, or both these salts. When its second base is potassa, it consists of one equivalent of tersulphate of alumina 171.7, one equiv. of sulphate of potassa 87.25, and twenty-four equiv. of water $216 = 474.95$. In the ammoniacal alum, the equiv. of sulphate of potassa is replaced by one of sulphate of ammonia. In other respects its composition is the same. *Alumina* is classed by the chemist as an earth.

It is essential to the constitution of true alum, as it cannot be replaced by any other base. It may be obtained by precipitating a solution of alum by water of ammonia, added in excess. As thus procured, it presents a gelatinous appearance, and is in the state of hydrate. In this form it has been used by some practitioners on the continent of Europe in diarrhœa. It consists of two equiv. of a metallic radical called *aluminium* 27·4, and three equiv. of oxygen 24=51·4. It is, therefore, a sesquioxide.

Medical Properties, &c. Alum, in ordinary medicinal doses, is astringent; in large doses, purgative. It is used both as an internal and local remedy. Internally it is employed as an astringent in passive hemorrhages, colliquative sweats, diabetes, and chronic dysentery and diarrhœa, also in gleet and leucorrhœa, in which latter diseases it is sometimes combined with cubebs. It has been recommended by Kreysig and Dzondi in dilatation of the heart and aortic aneurism. A striking case of benefit from alum in dilatation of the heart, by Schlesier, is given in the *Eclectic Journal of Medicine*, iv. 135, from the *Medicinische Zeitung*. In this case, the alum was given in combination with rhatany and digitalis. As a purgative, it has been employed in colica pictonum. The practice was introduced by a Dutch physician in 1752, and imitated by Dr. Percival with great success. Its use in this disease has been latterly revived, and its efficacy fully established by Kapeler and Gendrin, of Paris, and Copland, of London. It allays nausea and vomiting, relieves flatulence, mitigates the pain, and opens the bowels with more certainty than any other medicine. Its remarkable influence in allaying the tormina in this disease, has led some to attribute to it a sedative operation. Sometimes it is advantageous to conjoin opium and camphor.

The local applications of alum are numerous. In various anginose affections, it is found highly useful, applied topically either in powder or solution. When the affection is attended with membranous exudation, its efficacy has been particularly insisted on by Bretonneau, applied in solution prepared with vinegar and honey for adults, and in powder, by *insufflation*, in the cases of children. When used in the latter way, a drachm of finely powdered alum may be placed in one end of a tube, and then blown by means of the breath into the throat of the child. M. Velpeau, in 1835, extended the observations of M. Bretonneau, and has successfully applied alum, not only in simple inflammatory sorethroat, but in those forms of angina dependent on small-pox, scarlatina, &c. In these cases the powdered alum may be applied several times a day to the fauces by means of the index finger, so as to cover the affected surfaces. In relaxation of the uvula, and in the beginning of sorethroat, with or without membraniform exudation, a solution of alum forms one of our best gargles. It forms also a useful astringent wash in certain states of mercurial sore-mouth. In gleet and leucorrhœa the solution is an approved remedy, either alone or conjoined with sulphate of zinc. (See *Liquor Aluminis Compositus*, Lond.) It is frequently applied as a local styptic, in epistaxis, by means of a plug soaked in a saturated solution, and pressed up the nostril, and in menorrhagia, by a sponge soaked in a similar solution, and introduced into the vagina. In the latter stages of conjunctival inflammation it is often proper, and in the purulent ophthalmia of infants, it forms the most efficacious remedy we possess. In these cases it is sometimes applied in the form of the alum cataplasm. (See *Cataplasma Aluminis*, Dub.)

The ordinary dose of alum is from ten to twenty grains, repeated every two or three hours, taken in the form of pill or solution. To prevent nausea, nutmeg or some aromatic water may be added. In colica pictonum the

dose is from half a drachm to two drachms, given in solution every three or four hours. An elegant way of exhibiting alum, is in the form of *alum whey*, made by boiling two drachms of alum with a pint of milk, and then straining to separate the curd. The dose is a wine-glassful containing about fifteen grains of alum. As a collyrium the solution is made of various strengths, as four, six, or eight grains to the fluidounce of water. A solution containing from half an ounce to an ounce of alum to a pint of water, and sweetened with honey, forms a convenient gargle. Solutions for gleet and leucorrhœa, and as topical applications to ulcers, &c. must vary in strength according to the state of the parts to which they are applied.

AMMONIA.

Ammonia.

All the ammoniacal compounds owe their distinctive properties to the presence of a peculiar gaseous compound of hydrogen and nitrogen, called *ammonia*. It is most easily obtained by the action of lime on muriate of ammonia or sal ammoniac, when the lime unites with the muriatic acid, so as to form chloride of calcium and water, and expels the ammonia. It is transparent and colourless, like common air, but possesses a hot and acrid taste, and an exceedingly pungent smell. It has a powerful alkaline reaction, and from this property and its gaseous nature, was called the *volatile alkali* by the earlier chemists. Its sp. gr. is 0.59. It is irrespirable, the glottis closing spasmodically when the attempt is made to breathe it. It consists of one eq. of nitrogen 14.15, and three of hydrogen 3=17.15; or in volumes, of one volume of nitrogen and three volumes of hydrogen, condensed into two volumes. Its symbol is NH_3 .

The salts of ammonia may be divided into hydracid salts, and oxacid salts. Thus when muriatic acid unites with ammonia, we have the hydracid salt called muriate of ammonia, which is usually considered to be a compound of muriatic acid and ammonia, with the symbol NH_3HCl . But Berzelius supposes that, in the act of uniting, the hydrogen of the muriatic acid is transferred to the elements of the ammonia, and that the compound, thus formed, uniting with the chlorine, gives rise to a salt, represented by NH_4Cl . To this hypothetical compound (NH_4) Berzelius gives the name of *ammonium*, and, consequently, to muriate of ammonia, the appellation of *chloride of ammonium*.

Applying the same view to the oxacid salts of ammonia, Berzelius conceives that they are compounds of *oxide of ammonium* (NH_4O) with their several acids. It is found that the true oxacid salts of ammonia always contain one eq. of water, which cannot be separated from them without destroying their nature; and it is supposed that the elements of this eq. of water, united with the elements of one eq. of ammonia, form oxide of ammonium. To apply the new view to the sulphate of ammonia, this salt is usually considered to be a protohydrated sulphate of ammonia, ($\text{NH}_3\text{SO}_3\text{HO}$); but on the new view, it is the sulphate of oxide of ammonium, without water, ($\text{NH}_4\text{O}\text{SO}_3$).

The following is a table of the principal officinal preparations containing ammonia, in the British and United States Pharmacopœias, with the synonyms.

Ammoniaë Hydrosulphuretum, *Dub.*

The ammonia in the spirit of ammonia of the U.S. and Ed. Pharmacopœias is in the caustic state; in the corresponding preparations of the London and Dublin Colleges, it is carbonated. In the aromatic and fetid spirits of ammonia, the alkali is caustic in the Edinburgh preparations, but carbonated in those of the other Pharmacopœias. It is seen by the table that the *ammoniated tinctures* are made in the Edinburgh Pharmacopœia with the *simple* spirit of ammonia; while the other Pharmacopœias prepare them uniformly with the *aromatic* spirit.

LIQUOR AMMONIÆ FORTIOR. U.S.

Stronger Solution of Ammonia.

“An aqueous solution of Ammonia of the specific gravity 0.882.” *U. S. Off. Syn.* AMMONIÆ LIQUOR FORTIOR. *Lond.*; AMMONIÆ AQUA FORTIOR. *Ed.*

This preparation was first introduced into the London Pharmacopœia of 1836, and has since been successively admitted into those of Edinburgh and the United States. It is too strong for internal exhibition, but forms a convenient ammoniacal solution for reduction with distilled water, to the strength of ordinary official solution of ammonia (*Liquor Ammonia*), or for preparing strong rubefacient and vesicating lotions and liniments. (See *Lini-mentum Ammonia Compositum*, *Ed.*)

The U. States and London Pharmacopœias include this solution in the list of the *Materia Medica*; but in the Edinburgh Pharmacopœia, a formula is given for its preparation, which is as follows:

“Take of Muriate of Ammonia, *thirteen ounces*; Quicklime, *thirteen ounces*; Water, *seven fluidounces and a half*; Distilled Water, *twelve fluid-ounces*. Slake the Lime with the water, cover it up till it cool, triturate it well and quickly with the Muriate of Ammonia previously in fine powder, and put the mixture into a glass retort, to which is attached a receiver with a safety-tube. Connect with the receiver a bottle also provided with a safety-tube, and containing four ounces of the Distilled Water, but capable of holding twice as much. Connect this bottle with another loosely corked, and containing the remaining eight ounces of Distilled Water. The communicating tubes must descend to the bottom of the bottles at the further end from the retort; and the receiver and bottles must be kept cool by snow, ice, or a running stream of very cold water. Apply to the retort a gradually increasing heat till gas ceases to be evolved; remove the retort, cork up the aperture in the receiver where it was connected with the retort, and apply to the receiver a gentle and gradually increasing heat, to drive over as much of the gas in the liquid contained in it, but as little of the water, as possible. Should the liquid in the last bottle not have the density of 960, reduce it with some of the Stronger Aqua Ammonia in the first bottle, or raise it with Distilled Water, so as to form Aqua Ammonia of the prescribed density.”

In this process the ammonia is disengaged in the usual manner from muriate of ammonia by the action of lime, as explained under the head of *Liquor Ammonia*. But it is perceived by the details of the process that the Edinburgh College propose to obtain both the *stronger* and *ordinary* solution of ammonia at one operation. This is done by connecting two bottles with the retort, through an intervening empty receiver, and charging them severally with one-third and two-thirds of the prescribed distilled water. The receiver between the retort and the bottles serves to detain impurities. The water in the first bottle becomes nearly saturated with ammonia, a result which is favoured by the application of cold. After the gas has ceased to be disengaged from the retort, it is removed; and any ammonia which may have condensed with water in the receiver, is saved by being driven over by a gentle heat. As the water in the first bottle will not take up all the ammonia disengaged, the balance is allowed to pass into the second bottle, where it saturates the water to a greater or less extent, forming a weak aqueous ammonia. The aqueous ammonia in the first bottle is the Edinburgh *Ammonia Aqua Fortior*, and that in the second is

converted into *Liquor Ammonia* of the proper officinal strength, by the addition of aqueous ammonia from the first bottle, if too weak, or of distilled water, if too strong. The Edinburgh process has the merit of economizing the ammonia, which is more or less wasted in the processes of the other Pharmacopœias, and of furnishing two preparations at one operation.

Properties of Aqueous Ammonia of maximum strength. It is a colourless liquid, of a caustic, acrid taste, and peculiar, pungent smell. It is strongly alkaline, and immediately changes turmeric to reddish-brown when held over its fumes. Cooled down to 40° below zero, it concretes into a gelatinous mass, and at the temperature of 130° enters into ebullition, owing to the rapid disengagement of the gas. Its sp. gr. is 0.875 at 50° , when it contains 32.5 per cent. of ammonia.

Properties of the Officinal Stronger Solution of Ammonia. This has similar properties to those mentioned above. Its officinal sp. gr. is 0.882, *U. S., Lond.; 0.880, Ed.* When of the density 0.882, it contains about 29 per cent. of ammonia. The liquor ammonia fortior of the shops, is usually not so strong, commonly ranging in density from 0.886 to 0.910. Even though of proper officinal strength at first, it in general becomes gradually weaker by the escape of ammonia, in consequence of the bottle in which it is kept being inaccurately stopped, or occasionally opened. When pure it is wholly volatilized by heat. If precipitated by lime-water, it contains carbonic acid. After having been saturated with nitric acid, a precipitate produced by carbonate of ammonia indicates earthy impurity; by nitrate of silver, either muriatic acid or a chloride.

Liquor Ammonia Fortior is a convenient preparation for the apothecary, to make *Liquor Ammonia*, by a due dilution with distilled water; and the Pharmacopœias have given directions for this purpose. In the U. States and London Pharmacopœias the stronger solution is directed to be diluted with two measures of distilled water; in the Edinburgh, with two and a half measures. By dilution in these proportions, the stronger preparation is brought uniformly to the strength of *Liquor Ammonia* (sp. gr. 0.960.) The larger proportional amount of water directed by the Edinburgh College, is rendered necessary by the greater strength of their officinal stronger solution.

When purchasing or making the Stronger Solution of Ammonia, the apothecary should not trust to its being of the officinal strength; but ascertain the point by taking its density, either with the specific gravity bottle or the hydrometer. In reducing it to make *Liquor Ammonia*, the same precaution should be used; and if the mixture should not have the sp. gr. of 0.960, it should be brought to that density by the addition either of the stronger solution or of distilled water, as the case may require.

Medical Properties and Uses. This solution is too strong for employment in its unmixed state, unless for the purposes of a caustic. Its medical properties when duly reduced by admixture with other substances, will be given under the head of *Linimentum Ammonia Compositum*. It is used as a chemical agent to prepare two Edinburgh officinals, *Ferrugo* and *Ferri Oxidum Nigrum*.

B.

AMMONIÆ MURIAS. U.S., Ed., Dub.

Muriate of Ammonia.

“Chlorohydrate of Ammonia.” U.S.

Off. Syn. AMMONIÆ HYDROCHLORAS. Lond.

Sal ammoniac, Hydrochlorate of ammonia; Sel ammoniac, Fr.; Salmiak, Germ.; Sale ammoniaco, Ital.; Sal ammoniaco, Span.

This salt is placed in the *Materia Medica* list of all the *Pharmacopœias* mentioned in this work. It originally came from Egypt, where it was obtained by sublimation from the soot afforded by the combustion of camels' dung, which is used in that country for fuel.

Preparation. At present muriate of ammonia is derived from two principal sources, the ammoniacal liquor, called *gas liquor*, found in the condensing vessels of coal-gas works, and the brown, fetid ammoniacal liquor, known under the name of *bone spirit*, which is a secondary product, obtained, during the destructive distillation of bones, by the manufacturers of animal charcoal for the use of sugar-refiners. These two liquors are the parent of all the ammoniacal compounds; for while they are both used to obtain muriate of ammonia, this salt is employed, directly or indirectly, in obtaining all the other salts of ammonia.

The gas liquor contains carbonate, hydrocyanate, hydrosulphate, and sulphate of ammonia, but principally the carbonate. The first three salts are converted into the sulphate, by the addition of sulphuric acid, and due evaporation, whereby brown crystals of sulphate of ammonia are obtained. These are then sublimed with chloride of sodium in iron pots, lined with clay and furnished with a leaden dome or head. By the mutual action of the sulphate, chloride, and water, there are formed muriate of ammonia which sublimes into the head, and sulphate of soda which remains behind. Thus $\text{NH}_3, \text{SO}_3, \text{HO} + \text{NaCl}$ become $\text{NH}_3, \text{HCl} + \text{NaO}, \text{SO}_3$. Sometimes, instead of the ammonia being first converted into a sulphate, it is made at once into muriate of ammonia by the addition of muriatic acid or chloride of calcium. When chloride of calcium is employed, the chief reaction takes place between carbonate of ammonia and the chloride, with the result of forming muriate of ammonia in solution, and a precipitate of carbonate of lime. The solution is duly evaporated, whereby brown crystals of muriate of ammonia are obtained. These, after having been dried, are purified by sublimation in an iron subliming pot, coated with a composition of clay, sand, and charcoal, and covered with a dome of lead. These pots are sometimes sufficiently large to hold 500 pounds. “A gentle fire is kept up under the subliming pot for seven or eight days, when the dome having cooled down, and the sal ammoniac somewhat contracted, so as to loosen from the sides, the dome is thrown off from the iron pot, and about two or three hundred weight of white, semi-transparent muriate of ammonia are knocked off in cakes.” (*Pereira.*)

In the destructive distillation of bones for making animal charcoal, or indeed, of any animal substance whatever, the distilled products are the bone spirit already mentioned, being chiefly an aqueous solution of carbonate of ammonia, and an empyreumatic oil called *animal oil*. These products all result from a new arrangement of the ultimate constituents of the animal matter. Hydrogen and oxygen form water; carbon and oxygen, carbonic acid; nitrogen and hydrogen, ammonia; and hydrogen, carbon, and oxygen, the animal oil.

Muriate of ammonia may be obtained from bone spirit in the manner just described for procuring it from gas liquor. Sometimes, however, the sulphate of ammonia is not made by direct combination, but by digesting the bone spirit with ground plaster of Paris (sulphate of lime). By double decomposition, sulphate of ammonia and carbonate of lime are formed. The sulphate of ammonia being thus obtained as an intermediate step, it is converted into the muriate by sublimation with common salt, in the usual manner.

For obtaining muriate of ammonia, other processes, besides those given above, have been proposed or practised; for an account of which the reader is referred to the Chemical Essays of the late Mr. Parkes, who has appropriated a separate essay to the subject.

Commercial History. All the muriate of ammonia consumed in the United States is obtained from abroad. Its commercial varieties are known under the names of the *crude* and *refined*. The crude is imported from Calcutta in chests, containing from 350 to 400 pounds. This variety is consumed almost exclusively by coppersmiths and other artisans in brass and copper, being employed for the purpose of keeping the metallic surfaces bright, preparatory to brazing. The refined comes to us exclusively from England, packed in casks containing from 5 to 10 cwt.

Properties. Muriate of ammonia is a white, translucent, tough, fibrous salt, occurring in commerce in large cakes, about two inches thick, convex on one side and concave on the other. It has a pungent, saline taste, but no smell. Its sp. gr. is 1.45. It dissolves in three parts of cold, and one of boiling water, and cold is produced during its solution. It is less soluble in rectified spirit than in water, and sparingly so in absolute alcohol. A hot concentrated aqueous solution, as it cools, deposits the salt in feathery crystals. This salt is very difficult to powder in the ordinary way. Its pulverization, however, may be effected readily by making a boiling saturated solution of the salt, and stirring it as it cools. The salt may thus be made to granulate, and in this state, after having been drained from the remaining solution and dried, may be readily powdered. Muriate of ammonia, at a red heat, sublimes without decomposition, as its mode of preparation proves. Exposed to a damp atmosphere, it becomes slightly moist. It has the property of increasing the solubility of corrosive sublimate in water. (See *Liquor Hydrargyri Bichloridi*, Lond.) It is decomposed by the strong mineral acids, and by the alkalies and alkaline earths; the former disengaging muriatic acid, the latter, ammonia, both sensible to the smell. Muriate of ammonia is the salt usually employed for obtaining gaseous ammonia, which is conveniently disengaged by means of lime. Though neutral in composition, it slightly reddens litmus. It is incompatible with acetate of lead and nitrate of silver, producing a precipitate, with the former, of chloride of lead, with the latter, of chloride of silver.

According to the Edinburgh College, muriate of ammonia is not liable to adulteration. If it be not entirely volatilized by heat and soluble in water, it contains impurity. If the salt is entirely volatilized by heat, and yet produces a precipitate with chloride of barium, the presence of sulphate of ammonia is indicated.

Composition. Muriate of ammonia is composed of one eq. of muriatic acid 36.42, and one of ammonia 17.15 = 53.57; or, in ultimate constituents, of one eq. of chlorine, one of nitrogen, and four of hydrogen. Viewed as *chloride of ammonium*, it consists of one eq. of chlorine and one of ammonium (NH_4, Cl). In equivalent volumes, it consists of two volumes of muriatic acid gas, and two volumes of ammonia, condensed into a solid.

Medical Properties. Muriate of ammonia is employed both internally and externally. Internally it acts primarily on the alimentary canal, purging in large doses, but rather constipating in small ones. Its secondary action is alleged to be that of a stimulating alterative on the capillary, glandular and lymphatic systems, and on the mucous, serous, and fibrous tissues, the nutrition of which it is supposed to improve. It has been recommended in catarrhal and rheumatic fevers; in pleuritis, peritonitis, dysentery, and other inflammations of the serous and mucous membranes, after the first violence of the disease has abated; in chronic inflammation and enlargement of the thoracic and abdominal viscera; and in amenorrhœa, when dependent on deficient action of the uterus. Several cases of pectoral disease, simulating incipient phthisis, are reported to have been cured by this remedy in Otto's Bibliothek for 1834. The dose is from five to thirty grains, repeated every two or three hours, either given in powder mixed with powdered gum or sugar, or dissolved in syrup or mucilage. It is very little used as an internal remedy in the United States; but is a good deal employed on the continent of Europe, especially in Germany, where it is deemed a powerful alterative and resolvent. Considering the various testimony borne to its therapeutical powers, it is, perhaps, too little employed by our practitioners.

Externally, muriate of ammonia is used in solution as a stimulant and resolvent in contusions, indolent tumours, &c. The strength of the solution must be varied according to the intention in view. An ounce of the salt, dissolved in nine fluidounces of water and one of alcohol, forms a solution of convenient strength. When the solution is to be used as a wash for ulcers, or an injection in leucorrhœa, it should not contain more than from one to four drachms of the salt to a pint of water.

Much uncertainty long existed among botanists as to the plant which yields ammoniac. It was generally believed to be a species of *Ferula*, till Willdenow raised from some seeds mixed with the gum-resin found in the shops, a plant which he ascertained to be an *Heracleum*, and named *H. gummiferum*, under the impression that it must be the true source of the medicine. On this authority, the plant was adopted by the British Colleges, and recognised in former editions of our national Pharmacopœia. Willdenow expressly acknowledged that he could not procure from it any gum-resin, but ascribed the result to the influence of the climate. The *Heracleum*, however, did not correspond exactly with the representations given of the ammoniac plant

by travellers; and Sprengel ascertained that it was a native of the Pyrenees, and never produced gum. Mr. Jackson, in his account of Morocco, imperfectly describes a plant indigenous in that country, supposed to be a species of *Ferula*, from which gum-ammoniac is procured by the natives. This plant is believed by Lindley to be the *Ferula tingitana*, and its product is thought to be the ammoniacum of the ancients, which was obtained from Africa; but this is not the drug now used under that name, which is derived exclusively from Persia. M. Fontaniér, who was sent by the French Government into the Levant, and resided many years in Persia, saw the ammoniac plant growing in the province of Fars, and transmitted a drawing of it with specimens to Paris. From these it was inferred to be a species of *Ferula*; and Merat and De Lens proposed for it the name originally applied to it by Lemery, of *F. ammonifera*. It has subsequently, however, been ascertained, from specimens of the plant obtained in Persia by Colonel Wright, and examined by Dr. David Don, that it belongs to a genus allied to *Ferula*, but essentially different, and named by Mr. Don, *Dorema*. A description of it is contained in the 16th volume of the Linnean Transactions, under the name of *D. Ammoniacum*. This is now acknowledged by all the officinal authorities except the Dublin College.

The ammoniac plant grows spontaneously in Farsistan, Irauk, Chorassan, and other Persian provinces. Dr. Grant found it growing abundantly in Syghan near Bameean, on the northwest slope of the Hindoo Coosh mountains. (*Christison's Dispensatory*.) It attains the height of six or seven feet, and in the spring and early part of summer abounds in a milky juice, which flows out upon the slightest puncture. From the accounts of travellers it appears, that in the month of May, the plant is pierced in innumerable places by an insect of the beetle kind. The juice, exuding through the punctures, concretes upon the stem, and when quite dry is collected by the natives. M. Fontaniér states that the juice exudes spontaneously, and that the harvest is about the middle of June. According to Dr. Grant, the drug is collected in Syghan, like assafetida, from the root of the plant. The gum-resin is sent to Bushire, whence it is transmitted to India. It reaches this country usually by the route of Calcutta. The name of the drug is thought to have been derived from the temple of Jupiter Ammon in the Lybian desert, where the ammoniac of the ancients is said to have been collected; but Mr. Don considers it a corruption of *Armeniacum*, originating in the circumstance that the gum-resin was formerly imported into Europe through Armenia.

Properties. Ammoniac comes either in the state of separate tears, or in aggregate masses, and in both forms is frequently mixed with impurities. That of the tears, however, is preferable, as the purest may be conveniently picked out, and kept for use. These are of an irregular shape, usually more or less globular, opaque, yellowish on the outside, whitish within, compact, homogeneous, brittle when cold, and breaking with a conchoidal shining fracture. The masses are of a darker colour and less uniform structure, appearing, when broken, as if composed of numerous white or whitish tears, embedded in a dirty gray or brownish substance, and frequently mingled with foreign matters, such as seeds, fragments of vegetables, and sand, or other earth.

The smell of ammoniac is peculiar, and stronger in the mass than in the tears. The taste is slightly sweetish, bitter, and somewhat acrid. The sp. gr. is 1.207. When heated, the gum-resin softens and becomes adhesive, but does not melt. It burns with a white flame, swelling up, and emitting a smoke of a strong, resinous, slightly alliaceous odour. It is partly soluble

in water, alcohol, ether, vinegar, and alkaline solutions. Triturated with water, it forms an opaque milky emulsion, which becomes clear upon standing. The alcoholic solution is transparent, but is rendered milky by the addition of water. Bucholz obtained from 100 parts of ammoniac, 22·4 parts of gum, 72·0 of resin, 1·6 of bassorin, and 4·0 of water including volatile oil and loss. Braconnot obtained 18·4 per cent. of gum, 70·0 of resin, 4·4 of a gluten-like substance (bassorin), and 6·0 of water, with 1·2 per cent. of loss. Hagen succeeded in procuring the volatile oil in a separate state by repeated distillation with water. It has a penetrating disagreeable odour, and a taste at first mild, but afterwards bitter and nauseous. The resin of ammoniac is dissolved by alcohol, and the fixed and volatile oils, but is divided by ether into two resins, of which one is soluble, the other insoluble in that menstruum.

Medical Properties and Uses. This gum-resin is stimulant and expectorant, in large doses cathartic, and, like many other stimulants, may be so given as occasionally to prove diaphoretic, diuretic, or emmenagogue. It has been employed in medicine from the highest antiquity, being mentioned in the writings of Hippocrates. The complaints in which it is most frequently used are chronic catarrh, asthma, and other pectoral affections, attended with deficient expectoration without acute inflammation, or with a too copious secretion from the bronchial mucous membrane, dependent upon debility of the vessels. It is thought to have been useful in some cases of amenorrhœa, and in those chlorotic and hysterical conditions of the system arising out of this complaint. It has also been prescribed in obstructions or chronic engorgements of the abdominal viscera, under the vague notion of its deobstruent power. Any good which it may do in these affections, is more probably ascribable to its revulsive action upon the alimentary mucous membrane. Authors speak of its utility in long and obstinate colics dependent on mucous matter lodged in the intestines; but it would be difficult to ascertain in what cases such mucous matter existed, and, even allowing its presence, to decide whether it was a cause or a result of the diseased action. Ammoniac is usually administered in combination with other expectorants, with tonics, or emmenagogues. It is much less used than formerly. Externally applied in the shape of a plaster, it is thought to be useful as a discutient or resolvent in white swellings of the joints and other indolent tumours. (See *Emplastrum Ammoniaci*.)

It is given in substance, in the shape of pill or emulsion. The latter form is preferable. (See *Mistura Ammoniaci*.) The dose is from ten to thirty grains.

Gen. Ch. Calyx five-cleft, inferior. Petals five. Drupe with a nut perforated with pores. *Willd.*

Amygdalus communis. Willd. *Sp. Plant.* ii. 982; Woodv. *Med. Bot.* p. 507. t. 183. The almond tree rises usually from fifteen to twenty feet in height, and divides into numerous spreading branches. The leaves stand upon short footstalks, are about three inches long, and three quarters of an inch broad, elliptical, pointed at both ends, veined, minutely serrated, with the lower serratures and petioles glandular, and are of a bright green colour. The flowers are large, of a pale red colour varying to white, with very short peduncles and petals longer than the calyx, and are usually placed in numerous pairs upon the branches. The fruit is of the peach kind, with the outer covering thin, tough, dry, and marked with a longitudinal furrow, where it opens when fully ripe. Within this covering is a rough shell, which contains the kernel or almond.

There are several varieties of this species of *Amygdalus*, differing chiefly in the size and shape of the fruit, the thickness of the shell, and the taste of the kernel. The two most important are the *Amygdalus (communis) dulcis*, and the *Amygdalus (communis) amara*, the former bearing sweet, the latter bitter almonds. Another variety is the *fragilis* of De Candolle, which yields the soft-shelled almonds.

The almond tree is a native of Persia, Syria, and Barbary, and is very extensively cultivated in various parts of the South of Europe. It has been introduced into the United States; but in the northern and middle sections the fruit does not usually come to perfection. We are supplied with sweet almonds chiefly from Spain and the South of France. They are distinguished into the soft-shelled and hard-shelled, the former of which come from Marseilles and Bordeaux, the latter from Malaga. From the latter port they are sometimes brought to us without the shell. In British commerce, the two chief varieties are the *Jordan* and *Valentia* almonds, the former imported from Malaga, the latter from Valentia. The former are longer, narrower, more pointed, and more highly esteemed than the latter. The bitter almonds are obtained chiefly from Morocco, and are exported from Mogadore.

Properties. The shape and appearance of almonds are too well known to require description. Each kernel consists of two white cotyledons, enclosed in a thin, yellowish brown, bitter skin, which is easily separable after immersion in boiling water. When deprived of this covering, they are called *blanched almonds*. On exposure to the air they are apt to become rancid; but if thoroughly dried and kept in well closed glass vessels, they may be preserved unaltered for many years. The two varieties require each a separate notice.

1. **AMYGDALA DULCIS.** *Sweet Almonds.* These, when blanched, are without smell, and have a sweet, very pleasant taste, which has rendered them a favourite article of diet in almost all countries where they are readily attainable. They are, however, generally considered of difficult digestion. By the analysis of M. Boullay, it appears that they contain in 100 parts, 5 parts of pellicle, 54 of fixed oil, 24 of albumen, 6 of uncrystallizable sugar, 3 of gum, 4 of fibrous matter, 3.5 of water, and 0.5 of acetic acid comprising loss. The albumen differs somewhat from ordinary vegetable albumen, and has received the name of *emulsin*. It may be obtained separate by treating the emulsion of almonds with ether, allowing the mixture, after frequent agitation, to stand until a clear fluid separates at the bottom of the vessel, drawing this off by a syphon, adding alcohol to it so as to precipitate the emulsin, then washing the precipitate with fresh alcohol, and drying it under the receiver of an air-pump. In this state it is a white powder, inodorous and tasteless, soluble in water, and insoluble in ether and alcohol. Its solution coagulates at 212° . Its distinguishing property is that of producing certain changes hereafter to be noticed in amygdalin, which property it loses when coagulated by heat. (*Thomson and Richardson, Am. Journ. of Pharm.* x. 351, from *Athenæum*.) It consists of carbon, oxygen, hydrogen, and nitrogen, and is probably identical with the principle for which Robiquet proposed the name of *synaptase*. Thomson and Richardson suppose, from their experiments, that it may be an *amide*. (See *Althæa*.) The fixed oil, which may be obtained by expression, is colourless or slightly tinged with yellow, sweet and bland to the taste, and may be substituted for olive oil in most of the economical uses to which the latter is applied. (See *Oleum Amygdalæ*.) Almonds, when rubbed with water, form a milky emulsion, the insoluble matters being suspended by the agency of the albuminous, mucilaginous, and saccharine principles.

2. **AMYGDALA AMARA.** *Bitter Almonds.* These are smaller than the preceding variety. They have the bitter taste of the peach-kernel, and, though in their natural state inodorous or nearly so, have, when triturated with water, the fragrance of the peach blossom. They contain the same ingredients as sweet almonds, and like them form a milky emulsion with water. It was formerly supposed that they also contained hydrocyanic acid and an essential oil, to which their peculiar taste and smell, and their peculiar operation upon the system were ascribed. It has, however, been ascertained by MM. Robiquet and Boutron, that these principles do not pre-exist in the almond, but result from the reaction of water; and Wöhler and Liebig have proved, what was suspected by Robiquet, that they are formed out of a substance of peculiar properties, denominated *amygdalin*, which is the characteristic constituent of bitter almonds. This substance, which was discovered by Robiquet and Boutron, is white, crystallizable, inodorous, of a sweetish bitter taste, unalterable in the air, freely soluble in water and hot alcohol, very slightly soluble in cold alcohol, and insoluble in ether. Its elementary constituents are carbon, hydrogen, oxygen, and nitrogen; and it is supposed to be an *amide*; as, when treated with an alkali, it yields ammonia and a peculiar acid which has been named *amygdalic acid*. Liebig and Wöhler recommend the following process for procuring it, in which the object of the fermentation is to destroy the sugar with which it is associated. Bitter almonds, previously deprived of their fixed oil by pressure, are to be boiled in successive portions of alcohol till they are exhausted. From the liquors thus obtained, all the alcohol is to be drawn off by distillation, care being taken, near the end of the process, not to expose the syrupy residue to too great a heat. This residue is then to be diluted

with water, mixed with good yeast, and placed in a warm situation. After the fermentation which ensues has ceased, the liquor is to be filtered, evaporated to the consistence of syrup, and mixed with alcohol. The amygdalin is thus precipitated in connexion with a portion of gum, from which it may be separated by solution in boiling alcohol, which will deposite it upon cooling. If pure, it will form a perfectly transparent solution with water. Any oil which it may contain may be separated by washing it with ether. One pound of almonds yielded at least 120 grains of amygdalin. (*Annalen der Pharm.* xxii. and xxiii. 329.)

Amygdalin, when mixed with an emulsion of *sweet* almonds, gives rise, among other products, to the volatile oil of bitter almonds and hydrocyanic acid—the emulsin of the sweet almonds acting the part of a ferment, by setting on foot a reaction between the amygdalin and water; and the same result is obtained when pure *emulsin* is added to a solution of amygdalin. It appears then that the volatile oil and hydrocyanic acid, developed in bitter almonds when moistened, result from the mutual reaction of amygdalin, water, and emulsin. It is asserted that emulsin procured from other seeds, as those of the poppy, hemp, and mustard, is capable of producing the same reaction between water and amygdalin, though in a less degree than that of the sweet or bitter almonds. (*Annal. der Pharm.* xxviii. 290.)

Bitter almonds yield their fixed oil by pressure; and the essential oil, impregnated with hydrocyanic acid, may be obtained from the residue by distillation with water. This oil, usually called *oil of bitter almonds*, has a bitter, acrid, burning taste, and the peculiar odour of the kernel in a very high degree. It is of a yellowish colour, heavier than water, soluble in alcohol and ether, slightly soluble in water, and deposites, upon standing, a white crystalline substance, which consists chiefly of benzoic acid. It may be entirely freed from hydrocyanic acid, by agitating it strongly with hydrate of lime and a solution of chloride of iron, and submitting the mixture to distillation. The oil comes over with the water, from which it may be separated in the usual manner. Thus purified, it still retains its peculiar odour, with a burning and aromatic taste; but, as proved by Dr. Göppert of Breslau, is wholly destitute of those poisonous properties which distinguish the oil in its original state, and which depend on the presence of hydrocyanic acid. The odour of the oil of bitter almonds has been usually, but erroneously, ascribed to this acid, which, on examination, will be found to smell very differently. The same remark is applicable to the essential oils of the cherry laurel, of the bird cherry, and probably of other vegetables supposed to contain hydrocyanic acid. The benzoic acid which the oil of bitter almonds deposites upon standing, has been satisfactorily proved by Robiquet and Boutron not to pre-exist in the oil, but to result from the absorption of oxygen, and Wöhler and Liebig have rendered it probable that there exists a radical in the oil, consisting of carbon, hydrogen, and oxygen, which, though it has not yet been isolated, is a distinct substance, and constitutes the basis of numerous compounds. The oil is composed of this radical, called *benzule*, and hydrogen, with the former of which, oxygen when absorbed forms benzoic acid, and with the latter, water. The pure oil is therefore considered a *hydruret of benzule*.

The essential oil of bitter almonds operates upon the system in a manner closely analogous to that of hydrocyanic acid. A single drop is sufficient to destroy a bird, and four drops have occasioned the death of a dog of middle size. The distilled water of bitter almonds operates in a similar manner, though less powerfully; and the almonds themselves have proved deleterious when taken in considerable quantities. Confectioners employ bitter

almonds for communicating flavour to the syrup of orgeat. (See *Syrupus Amygdalæ*.) The kernel of the peach possesses similar properties, and is frequently used as a substitute. The oil of bitter almonds is much used by the perfumers.

Medical Properties and Uses. Sweet almonds exercise no other influence upon the system than that of a demulcent. The emulsion formed by triturating them with water is a pleasant vehicle for the administration of other medicines, and is itself useful in cases of catarrhal affection. Bitter almonds are more energetic, and, though not much in use, might undoubtedly be employed with advantage in cases to which the hydrocyanic acid is applicable. An emulsion made with them has been beneficially prescribed in pectoral affections attended with cough, and is said to have cured intermittents when bark has failed. (*Bergius, Mat. Med.*) It probably operates by diminishing the excitability of the nervous system, and moderating existing irritation. Dr. A. T. Thomson says that he has found it extremely useful as a lotion in acne rosea and in impetigo. Bitter almonds are said by Hufeland to have been successfully employed for the expulsion of the tape worm. In some persons they produce urticaria when taken in the smallest quantities.

The *oil of bitter almonds* might probably be substituted with advantage for the medicinal hydrocyanic acid; as the acid contained in the oil is much less liable to decomposition, remaining for several years unaltered, if the oil is preserved in well stopped bottles. According to Schrader, 100 parts of the oil contain sufficient acid for the production of 22·5 parts of Prussian blue. From this fact it may be inferred, that the oil is about four times as strong as our official hydrocyanic acid, and may therefore be given in the dose of from a quarter of a drop to a drop, to be gradually and very cautiously increased till some effect upon the system is observed. It may be administered in emulsion with gum Arabic, loaf sugar, and water. It has been employed externally, dissolved in water in the proportion of one drop to a fluidounce, in prurigo senilis and other cases of troublesome itching. To facilitate the solution in water, the oil may be previously dissolved in spirit.

Wöhler and Liebig propose, as a substitute for cherry-laurel-water, which owes its effects to the hydrocyanic acid it contains, but is objectionable from its unequal strength, an extemporaneous mixture, consisting of 17 grains of amygdalin, and one fluidounce of an emulsion made with two drachms of *sweet* almonds, and a sufficient quantity of water. This mixture contains, according to the above named chemists, one grain of absolute hydrocyanic acid, and is equivalent to two fluidounces of fresh cherry-laurel water. If it be found to answer in practice, it will have the great advantage of certainty in relation to the dose; as amygdalin may be kept any length of time unaltered. If the calculation of Wöhler and Liebig be correct as to the quantity of acid it contains, not more than a fluidrachm should be given as a commencing dose.

AMYGDALUS PERSICA. Folia. *Dub.**Peach Leaves.*

Pecher, *Fr.*; Pfirsichbaum, *Germ.*; Persico, *Ital.*; Alberchigo, *Span.*

AMYGDALUS. See AMYGDALA.

Amygdalus Persica. Willd. *Sp. Plant.* ii. 982; Woodv. *Med. Bot.* p. 511. t. 184.—*Persica vulgaris.* Miller, Lamarck. Every one is familiar with the appearance of the common peach tree. It is characterized specifically by having “all the serratures of the leaves acute, and by its sessile solitary flowers.” Though its native country is not certainly known, it is generally supposed to have been brought originally from Persia. In no country, perhaps, does it attain greater perfection, as regards the character of its fruit, than in the United States.

Peaches are among the most grateful and wholesome of our summer fruits. They abound in saccharine matter, which renders their juice susceptible of the vinous fermentation; and a distilled liquor prepared from them has been much used in some parts of the country under the name of peach brandy.

The kernels of the fruit bear a close resemblance in appearance and properties, and probably in chemical nature, to bitter almonds, for which they are frequently, and without inconvenience, substituted in our shops. They are employed by distillers in the preparation of *liqueurs*, and by cake-bakers to give flavour to various productions of their ovens; and are said to yield as much amygdalin as bitter almonds.

The flowers, leaves, and bark also have the peculiar odour and taste of bitter almonds, and would probably yield hydrocyanic acid. The leaves afford a volatile oil by distillation. These are the only part directed by the Dublin College.

Medical Properties, &c. Peach leaves are said to be laxative; and they probably exert, to a moderate extent, a sedative influence over the nervous system. They have been used as an anthelmintic with great reported success. More recently their infusion has been recommended in irritability of the bladder, in sick stomach, and whooping-cough. Half an ounce of the dried leaves may be infused in a pint of boiling water, and half a fluidounce given for a dose three times a day, or more frequently. Dr. Dougos gives, in whooping-cough, a pint of the strong infusion, in small doses, in the course of the day. (*Journ. de Pharm.* xxiii. 356.)

The flowers also are laxative; and a syrup prepared from them is considerably used, in infantile cases, upon the continent of Europe. Woodville states that a drachm of the dried flowers, or half an ounce in their recent state, given in infusion, is the dose as a vermifuge. Cases of fatal poisoning from their use in children are on record.

The kernels have more of the peculiar powers of hydrocyanic acid, and therefore require to be used with some caution. Blanched, and rubbed up with hot water, they form an emulsion well adapted to coughs depending on or associated with nervous irritation.

The dried fruit stewed with sugar is an excellent laxative article of diet, suitable to cases of convalescence attended with torpid bowels. W.

AMYLUM. U.S., Lond., Ed.

Starch.

“The fecula of the seeds of *Triticum vulgare*.” *U. S., Ed.* “*Triticum hybernum. Seminum Fæcula.*” *Lond.*

Amidon, *Fr.*; Stärkmehl, *Germ.*; Amido, *Ital.*; Almidon, *Span.*

Starch is a proximate vegetable principle contained in most plants, and especially abundant in the various grains; such as wheat, rye, barley, oats, rice, maize, &c.; in other seeds, as peas, beans, chestnuts, acorns, &c.; and in numerous tuberous roots, as those of the potato (*Solanum tuberosum*), the sweet potato (*Convolvulus Batatas*), the arrow-root, the cassava plant, and different species of Curcuma. The process for obtaining it consists essentially in reducing the substances in which it exists to a state of minute division, agitating or washing them with cold water, straining or pouring off the liquid, and allowing it to stand till the fine fecula which it holds in suspension has subsided. This, when dried, is starch, more or less pure according to the care taken in conducting the process. The starch of commerce is procured chiefly from wheat, sometimes also from potatoes. Our space will not allow us to enter into details in relation to the particular steps of the operation to which these substances are subjected; and the omission is of less consequence, as starch is never prepared by the apothecary.

Starch is white, pulverulent, opaque, and as found in the shops, is usually in columnar masses, having a somewhat crystalline aspect, and producing a peculiar sound when pressed between the fingers. Its specific gravity is 1.53. When exposed to a moist air, it absorbs a considerable quantity of water, which may be driven off by a gentle heat. It is insoluble in alcohol, ether, and cold water; but unites with boiling water, which, on cooling, forms with it a soft semi-transparent paste, or a gelatinous opaline solution, according to the proportion of starch employed. The paste, placed on folds of blotting paper, renewed as they become wet, abandons its water, contracts, and assumes the appearance of horn. If the proportion of starch be very small, the solution after slowly depositing a very minute quantity of insoluble matter, continues permanent, and upon being evaporated yields a semi-transparent mass, which is partially soluble in cold water. The starch has, therefore, been modified by the combined agency of water and heat; nor can it be restored to its original condition. Exposed, in the dry state, to a temperature somewhat above 212°, it undergoes, according to Caventou, a similar modification; and a degree of heat sufficient to roast it slightly converts it into a substance soluble in cold water, and applicable to the same purposes as gum in the arts. The same change in regard to solubility is, to a certain extent, produced by mechanical means, as by trituration in a mortar; and that the effect is not the result of heat evolved by friction, is evinced by the fact that it takes place when the starch is triturated with water. The views now generally entertained in relation to starch, by which the above mentioned phenomena may be most conveniently explained, are those originally presented by Raspail, and subsequently confirmed and extended by Guibourt, Guérin, and others. According to these views, starch consists of organized granules, which, examined by the microscope, appear to be of various form and size. These granules consist of a thin exterior pellicle or tegument, and of an interior substance, the former wholly insoluble, the latter soluble in water. The former constitutes, according to M. Payen, only 4 or 5 thousandths of the weight of starch. In relation to the interior

portion different opinions are entertained. M. Guérin thinks that it consists of two distinct substances, one soluble in cold water, the other soluble at first in boiling water but becoming insoluble by evaporation. Thus, when one part of starch is boiled for fifteen minutes in one hundred parts of water, and the liquid is allowed to stand, a small portion, consisting of the broken teguments, is gradually deposited. If the solution be now filtered and evaporated, another portion is deposited which cannot afterwards be dissolved. When wholly deprived of this portion and evaporated to dryness, the solution yields the part soluble in cold water. According to MM. Payen and Persoz, the interior portion of the globules consists only of a single substance, which is converted into the two just mentioned by the agency of water; and Thenard is inclined to the same opinion. An appropriate name for the interior soluble portion of starch is *amidin*, which has been adopted by some chemists. Starch, in its perfect state, is not affected by cold water, because the exterior insoluble tegument prevents the access of the liquid to the interior portion; but when the pellicle is broken by the agency of heat, or by mechanical means, the fluid is admitted, and the starch partially dissolved.*

Iodine forms with starch, whether in its original state or in solution, a blue compound; and the tincture of iodine is the most delicate test of its presence in any mixture. The colour varies somewhat according to the proportions employed. When the two substances are about equal, the compound is of a beautiful indigo blue; if the iodine is in excess, it is blackish-blue; if the starch, violet-blue. A singular property of the iodide of starch is that its solution becomes colourless if heated to about 200° , and afterwards recovers its blue colour upon cooling. By boiling, the colour is permanently lost. Alkalies unite with starch, forming soluble compounds, which are decomposed by the acids, the starch being precipitated. It is thrown down from its solution by lime-water and baryta water, forming insoluble compounds with these earths. The solution of subacetate of lead precipitates it in combination with the oxide of the metal. Starch may be made to unite with tannin by boiling their solutions together; and a compound results, which, though retained by the water while hot, is deposited when it cools. By long boiling with diluted sulphuric or muriatic acid, it is converted first into *dextrine*,† and ultimately into a saccharine substance similar to the sugar of grapes. A similar conversion into dextrine and the sugar of grapes is effected by means of a principle called *diastase*, discovered by MM. Payen and Persoz in the seeds of barley, oats, and wheat, after germination. (See *Hordeum*.) Strong muriatic and nitric acids dissolve it; and the latter, by the aid of heat, converts it into oxalic and malic acids. Concentrated sulphuric acid decomposes it. Mixed with hot water and exposed to a temperature of 70 or 80° , it undergoes fermentation, which results in the formation of several distinct principles, among which are sugar, a gummy substance (perhaps *dextrine*), and a modification of starch which De Saussure called *amidine*.

The tegumentary portion of starch, for which the name of *amylin* has been proposed, when entirely freed from the interior soluble matter, is wholly insoluble in water even by prolonged boiling, is insoluble in alcohol,

* See *Am. Journ. of Pharm.* xi. 265, for an interesting paper by Wm. Procter, Jun., on the various opinions in relation to the nature of starch.

† *Dextrine* is a substance resembling gum in appearance and properties, but differing from it in not affording mucic acid by the action of nitric acid. It is largely dissolved by water, hot or cold, and forms a mucilaginous solution, from which it is precipitated by alcohol. This fluid has no action on dextrine.

and suffers no change by the action of iodine or diastase. The acids, however, act upon it as they do upon starch. It approaches nearer in properties to lignin than any other principle.

Starch, as obtained from different substances, is somewhat different in its characters. *Wheat starch*, when examined by a microscope, is found to consist of granules of various sizes, usually rounded, but uneven upon the surface, and mixed with loose integuments, resulting from the process of grinding. It has also a certain degree of hardness and adhesiveness, owing, according to Guibourt, to the escape of a portion of the interior substance of the broken granules, which attracts some moisture from the air, and thus becoming glutinous, acts as a bond between those which remain unbroken. Another opinion attributes this peculiar consistence to the retention of a portion of the gluten of the wheat flour, which causes the granules to cohere. *Potato starch* is employed in various forms, being prepared so as to imitate more costly amylaceous substances, such as arrow-root and sago. In its ordinary state, it is more pulverulent than wheat starch, and may be distinguished, with the aid of the microscope, by the size of its granules, which, according to Raspail, are larger than those of any other known fecula. They are exceedingly diversified in size and shape, though their regular form is thought to be ovate. They are characterized by concentric rings or rugæ, which are most readily distinguishable in the fresh starch, and are said by Raspail to disappear upon desiccation. The characters of other kinds of fecula will be given under the heads of the several official substances of which they constitute the whole or a part.

Starch consists of carbon, hydrogen, and oxygen—its formula, from whatever source it may be derived, being, according to the latest opinions, $C_{12}H_{40}O_{10}$.

Medical Properties, &c. Starch is nutritive and demulcent, but in its ordinary form is seldom administered internally. Powdered and dusted upon the skin, it is sometimes used to absorb irritating secretions, and prevent excoriation. Dissolved in hot water and allowed to cool, it is often employed in enemata, either as a vehicle of other substances, or as a demulcent application in irritated states of the rectum. It may be used as an antidote to iodine taken in poisonous quantities.

Gen. Ch. Fruit nearly ovate, compressed, striated. *Petals* involuted, entire. *Willd.*

Anethum graveolens. Willd. *Sp. Plant.* i. 1469; Woodv. *Med. Bot.* p. 125. t. 48. Dill is an annual plant, three or four feet high, with a long spindle-shaped root; an erect, striated, jointed, branching stem; and bipinnate or tripinnate, glaucous leaves, which stand on sheathing footstalks, and have linear and pointed leaflets. The flowers are yellow, and in large, flat, terminal umbels, destitute of involucre. The plant is a native of Spain,

Portugal, and the South of France; and is found growing wild in various parts of Africa and Asia. It is cultivated in all the countries of Europe, and has been introduced into our gardens. The seeds, as the fruit is commonly called, are the only part used. They are usually rather more than a line in length, and less than a line in breadth, of an oval shape, thin, concave on one side, convex and striated on the other, of a brown colour, and surrounded by a yellowish membranous expansion. Their smell is strong and aromatic, but less agreeable than that of fennel-seed; their taste, moderately warm and pungent. These properties depend on a volatile oil, which may be obtained separate by distillation. It is of a pale yellow colour, and of the sp. gr. 0.881. The bruised seeds impart their virtues to alcohol and to boiling water.

Medical Properties. Dill seeds have the properties common to the aromatics, but are very seldom used in this country. They may be given in powder or infusion. The dose is from fifteen grains to a drachm.

ANGELICA. *U.S. Secondary.*

Angelica.

“The root and herb of *Angelica atropurpurea*.” *U.S.*

ANGELICA. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Apiaceæ or Umbelliferae.

Gen. Ch. Fruit elliptic, compressed, somewhat solid and corticate, ridges three, dorsal acute, intervals grooved, margin alated. *General involucre* none. (*Sprengel.*) *Umbel* large, many-rayed, spreading; *umbellet* dense, subhemispheric; *involucell* about eight-leaved. *Calyx* five-toothed. *Petals* inflected. *Nuttall.*

Angelica atropurpurea. Willd. *Sp. Plant.* i. 1430. This indigenous species of *Angelica*, sometimes called *masterwort*, has a perennial purplish root, and a smooth herbaceous stem, the dark colour of which has given rise to the specific name of the plant. The leaves are ternate, and supported by very large inflated petioles. The partitions of the leaf are nearly quinate, with ovate, acute, deeply serrate, somewhat lobed leaflets, of which the three terminal are confluent. The flowers are greenish-white.

The purple angelica extends throughout the United States from Canada to Carolina, growing in meadows and marshy woods, and flowering in June and July. It is smaller than the *A. Archangelica*, with a less succulent stem. The whole plant is officinal. It has a strong odour, and a warm aromatic taste. The juice of the recent root is acrid, and is said to be poisonous; but the acrimony is dissipated by drying.

Medical Properties, &c. The medical virtues of the plant are similar to those of the garden *Angelica* of Europe, for which it has been proposed as a substitute. It is, however, little employed. An infusion is occasionally used in flatulent colic; and we are told that the stems are sometimes candied by the country people.

ANGELICA. Ed.

Root of Garden Angelica.

“Root of Angelica Archangelica.” Ed.

Angelique, *Fr.*; Engelwurzel, *Germ.*; Arcangelica, *Ital.*; Angelica, *Span.*ANGELICA. See ANGELICA. *U. S.*

Angelica Archangelica. Willd. *Sp. Plant.* i. 1428; Woodv. *Med. Bot.* p. 86. t. 35.—*Archangelica officinalis.* Hoch, De Cand. &c. *Garden angelica* has a long, thick, fleshy, biennial root, furnished with many fibres, and sending up annually a hollow, jointed, round, channeled, smooth, purplish stem, which rises five feet or more in height, and divides into numerous branches. The leaves, which stand upon round fistulous footstalks, are very large, doubly pinnate, with ovate lanceolate, pointed, acutely serrate leaflets, of which the terminal one is three-lobed. The flowers are small, greenish-white, and disposed in very large, many-rayed, terminal umbels, composed of numerous dense, hemispherical umbelllets.

This plant is a native of the North of Europe, and is found in the high, mountainous regions in the southern section of that continent, as in Switzerland and among the Pyrennees. It has become an object of culture in various parts of Europe, and may be occasionally met with in the gardens of this country. It flowers during the summer. The whole plant has a fragrant odour, and possesses aromatic properties; but the root and fruit only are official.

1. *The root* should be dug up in the autumn of the first year, as it is then less liable to become mouldy and worm-eaten than when taken from the ground in the spring. It is spindle-shaped, an inch or more in thickness at its upper extremity, and beset with numerous long descending radicles. The fresh root has a yellowish-gray epidermis, a fleshy yellow parenchyma, and when wounded yields a honey-coloured juice, which has all the aromatic properties of the plant. The dried root is grayish-brown and much wrinkled externally, whitish and spongy within, breaking with a starchy fracture, exhibiting shining resinous points. It is very apt to be attacked by worms; and is said to keep best, in the state of powder, in full and well closed vessels. The smell is strong and fragrant, the taste at first sweetish, afterwards warm, aromatic, bitterish, and somewhat musky. These properties are extracted by alcohol, and less perfectly by water. The constituents of the root, according to John, are an essential oil, gum, inulin, bitter extractive, an acrid resin, lignin, and a peculiar principle soluble only in a solution of potassa. Five hundred parts yield by distillation nearly four parts of volatile oil.

2. *The seeds*, as the fruit is commonly called, are two or three lines long, oval, obtuse or somewhat notched at the ends, flat, and marked with a longitudinal furrow on one side, convex with three angular ridges on the other. They are ash-coloured, and have the same smell and taste as the root. M. Fée says that they keep well.

Medical Properties. Angelica is an elegant aromatic tonic; but is little employed in the United States. The Laplanders, in whose country it

flourishes, are said to esteem it highly as a condiment and medicine. In Europe, the stems are frequently made into a preserve, and used in desserts in order to excite the stomach. The dose of the root or seeds is from thirty grains to a drachm.

ANGUSTURA. U.S.

Angustura Bark.

"The bark of *Galipea officinalis*. *Hancock.*" *U. S.*

Off. Syn. CUSPARIA. *Galipea Cusparia*. *Cortex. Lond.*; CUSPARIA. Bark of *Galipea officinalis*, *Ed.*; ANGUSTURA. BONPLANDIA TRIFOLIATA. *Cortex. Dub.*

Angusture, Fr.; *Angusturarinde, Germ.*; *Corteccia dell' Angustura, Ital.*; *Corteza de Angostura, Span.*

The subject of Angustura bark, in its botanical relations, has been involved in some confusion. The drug was at first supposed to be derived from a species of Magnolia, and in Europe was referred by some to the *Magnolia glauca* of this country. Humboldt and Bonpland were the first to enlighten the medical public as to its true source; though the name which it bore was sufficient to indicate the neighbourhood of its growth. These gentlemen, when at Angustura, a South American city upon the banks of the Orinoco, received specimens of the foliage of the plant from which the bark was obtained; and afterwards believed that they had found the same plant in a tree growing in the vicinity of Cumana. This latter they had the opportunity of personally inspecting, and were therefore enabled to describe accurately. Unable to attach it to any known genus, they erected it into a new one, with the title of *Cusparia*, a name of Indian origin, to which they added the specific appellation of *febrifuga*. On the authority of these botanists, the *Cusparia febrifuga* was generally believed to be the true source of the medicine, and was recognised as such by the London College. A specimen having in the mean time been sent by them to Willdenow, the name of *Bonplandia* was imposed on the new genus by that celebrated botanist; and was subsequently adopted by Humboldt and Bonpland themselves, in their great work on equinoctial plants. Hence the title of *Bonplandia trifoliata*, by which the tree is described in many works of *Materia Medica*. De Candolle, however, having found in the description all the characters of the genus *Galipea* of Aublet, has rejected both these titles, and proposes to substitute that of *Galipea Cusparia*, which has been adopted by the London College in the last edition of their Pharmacopœia. After all these commutations, however, it appears from the researches of Dr. Hancock, who resided for several months in the country of the Angustura bark tree, that the plant described by Humboldt and Bonpland is not that which yields the medicine, but probably another species of the same genus, which these authors had mistaken for it, having been led into error by the imperfect specimens which they received.* Among other striking differences in the two plants, is that of their size; the tree described by Humboldt and Bonpland being of great magnitude, attaining the height of sixty or eighty feet, while that from which the bark is obtained is never higher than twenty feet. Hancock proposes for the latter the title of *Galipea officinalis*, which has been adopted in the United States and Edinburgh Pharmacopœias.

GALYPEA. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Rutacæ.

* See a paper by John Hancock, M.D., in the Transactions of the London Medico-Botanical Society.

Gen. Ch. Corolla inferior, irregular, four or five cleft, hypocrateriform. Stamens four; two sterile. *Loudon's Encyc.*

Galipea officinalis. Hancock, *Trans. Lond. Medico-Bot. Soc.* This is a small tree, irregularly branched, rising to the medium height of twelve or fifteen feet, with an erect stem from three to five inches in diameter, and covered with a smooth gray bark. The leaves are alternate, petiolate, and composed of three leaflets, which are oblong, pointed at each extremity, from six to ten inches in length, from two to four in breadth, and supported upon the common petiole by short leafstalks. They are very smooth and glossy, of a vivid green colour, marked occasionally with small whitish round spots, and, when fresh, of a strong odour resembling that of tobacco. The flowers are numerous, white, arranged in axillary and terminal, peduncled racemes, and exhale a peculiar unpleasant odour. The fruit consists of five bivalve capsules, of which two or three are commonly abortive. The seeds, two of which are contained in each capsule, one often abortive, are round, black, and of the size of a pea.

This tree grows in great abundance on the mountains of Carony, situated between the 7th and 8th degrees of N. latitude; and is well known in the missions of Tumeremo, Uri, Alta Gracia, and Cupapui, near the Orinoco, upwards of two hundred miles from the ocean. It flourishes at the height of from six hundred to one thousand feet above the level of the sea. Its elegant white blossoms, which appear in vast profusion in August and September, add greatly to the beauty of the scenery.

The bark is generally brought from the West India ports packed in casks; but, according to Mr. Brande, the original package, formed in Angustura or its neighbourhood, consists of the leaves of a species of palm, surrounded by a network made of sticks.

Properties. The pieces are of various lengths, for the most part slightly curved, rarely quilled, sometimes nearly flat, from half a line to a line or more in thickness, pared away towards the edges, covered externally with a light yellowish-gray or whitish wrinkled epidermis, easily scraped by the nail, and internally of a yellowish-fawn colour. They are very fragile, breaking with a short resinous fracture, and yield, on being pulverized, a pale yellow powder; but when macerated for a short time in water, they become soft and tenacious, and may be cut into strips with scissors. The smell of Angustura bark is peculiar and disagreeable when fresh, but becomes fainter with age; the taste is bitter and slightly aromatic, leaving a sense of pungency at the end of the tongue. According to Fischer, it contains volatile oil, bitter extractive, a hard and bitter resin, a soft resin, a substance analogous to caoutchouc, gum, lignin, and various salts. The volatile oil, which may be obtained by distillation with water, is of a light-yellowish colour, lighter than water, of an acrid taste, and of the odour of the bark. The active principles are probably the volatile oil, bitter extractive, and bitter resin. The bark imparts its virtues to water and alcohol.*

Dr. A. T. Thomson states that precipitates are produced with the infusion by the solutions of sulphate of iron, tartrate of antimony and potassa,

* In the *Journal de Pharmacie*, tom. xxii. p. 662, we find a notice extracted from the *Jahresbericht* for 1835, in which it is stated, that when an infusion of Angustura bark is treated with absolute alcohol, at the common temperature, and allowed to evaporate spontaneously, tetrahedral crystals of peculiar substance are deposited, which Saladin, its discoverer, proposes to call *cusparin*. This principle is strictly neutral, fusible at a gentle heat, by which it loses 23.09 per cent. of its weight, soluble in 200 parts of cold, and 100 parts of boiling water, soluble in the concentrated acids and in the alkalies, and precipitated by the infusion of galls.

sulphate of copper, acetate and subacetate of lead, bichloride of mercury, nitrate of silver, and pure potassa; by nitric and sulphuric acids; and by the infusions of galls and yellow cinchona; but how far these substances are medicinally incompatible with the bark, it would be difficult in the present state of our knowledge to determine.

FALSE ANGUSTURA. Under this title, the European writers on *Materia Medica* describe a bark which has been introduced on the continent mixed with the true *Angustura* bark, and which, possessing poisonous properties, has in some instances produced unpleasant effects when prescribed by mistake for that medicine. It is distinguished by its greater thickness, hardness, weight, and compactness; by its resinous fracture; by the appearance of its epidermis, which is sometimes covered with a ferruginous efflorescence, sometimes is yellowish-gray, and marked with prominent white spots; by the brownish colour and smoothness of its internal surface, which is not, like that of the genuine bark, separable into laminæ; by the white slightly yellow powder which it yields; by its total want of odour, and its intense tenacious bitterness. When steeped in water, it does not become soft like the true *Angustura*. Analyzed by Pelletier and Caventou, it was found to contain a peculiar alkaline principle which they called *brucia*, and upon which its poisonous operation depends. Of this alkali we shall have occasion to speak in another place. (See *Nux Vomica*.) In consequence of its presence, a drop of nitric acid upon the internal surface of the bark produces a deep blood-red spot. The same acid applied to the external surface renders it emerald-green. In the true *Angustura* bark, a dull red colour is produced by the acid on both surfaces. The *false Angustura* was at first supposed to be derived from the *Brucea antidysenterica*; and was afterwards referred to some unknown species of *Strychnos*, in consequence of containing *brucia*, which is a characteristic ingredient of this genus of plants. At present, it is generally believed to be derived from the *Strychnos Nux vomica*, the bark of which, according to Dr. O'Shaughnessy, exactly corresponds with the description given by authors of the false *Angustura*, and like it contains *brucia*. Very little of the false *Angustura* bark reaches the United States. The only specimens we have ever seen, are some which have been sent hither from Europe as objects of curiosity.

Medical Properties and Uses. *Angustura* bark had been long used by the natives of the country where it grows, before it became known in Europe. From the continent its employment extended to the West Indies, where it acquired considerable reputation. It was first taken to Europe about fifty years since, and attracted particular attention among the English physicians. It is now ranked among the officinal remedies throughout Europe and America; but has not sustained the estimation in which it was at first held; and in the United States is not much prescribed. Its operation is that of a stimulant tonic. In large doses it also evacuates the stomach and bowels, and is often employed for this purpose in South America. It was at one time considerably used as a febrifuge in the place of Peruvian bark; but has not been found generally successful in the intermittents of northern latitudes. It is said to be particularly efficacious in bilious diarrhœas and dysenteries; and has been recommended in dyspepsia, and other diseases in which a tonic treatment is demanded. The testimony, however, of practitioners in Europe and the United States, is not strongly in its favour; and it is probably better adapted to tropical diseases, than to those of temperate climates. Hancock employed it very extensively in the malignant bilious intermittent fevers, dysenteries, and dropsies of *Angustura* and Demarara; and speaks in the strongest terms of its efficacy in these complaints. The form in which

he used it was that of fermented infusion, as recommended by the native practitioners. It has this advantage over Peruvian bark, that it is less apt to oppress the stomach.

It may be given in powder, infusion, tincture, or extract. The dose in substance is from ten to thirty grains. In larger quantities it is apt to produce nausea. From five to fifteen grains is the dose of the extract, which, however, according to Dr. Hancock, is inferior to the powder or infusion. To obviate nausea, it is frequently combined with aromatics.

PIMPINELLA. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Apiaceæ or Umbelliferæ.

Gen. Ch. Fruit ovate-oblong. *Petals* inferior. *Stigma* nearly globular. *Willd.*

Pimpinella Anisum. Willd. *Sp. Plant.* i. 1473; Woodv. *Med. Bot.* p. 135. t. 52. This is an annual plant, about a foot in height, with an erect, smooth, and branching stem. The leaves are petiolate, the lower roundish-cordate, lobed, incised-serrate, the middle pinnate-lobed with cuneate or lanceolate lobes, the upper trifid, undivided, linear. The flowers are white, and in terminal compound umbels, destitute of involucre.

The anise plant is a native of Egypt and the Levant, but has been introduced into the South of Europe, and is cultivated in various parts of that continent. It is also cultivated occasionally in the gardens of this country. The fruit is abundantly produced in Malta and Spain. The Spanish is smaller than the German or French, and is usually preferred.

Anise seeds (botanically fruit) are about a line in length, oval, striated, somewhat downy, attached to their footstalks, and of a greenish-brown colour, with a shade of yellow. Their odour is fragrant and increased by friction; their taste warm, sweet, and aromatic. These properties, which depend upon a peculiar volatile oil, are imparted sparingly to boiling water, freely to alcohol. The volatile oil exists in the envelope of the seeds, and is obtained separate by distillation. (See *Oleum Anisi.*) Their internal substance contains a bland fixed oil. By expression, a greenish oil is obtained, which is a mixture of the two. The seeds are sometimes adulterated with small fragments of argillaceous earth; and their aromatic qualities are occasionally impaired, in consequence of a slight fermentation, which they are apt to undergo in the mass, when collected before maturity.

The *Star aniseed*, the *badiane* of the French writers, though analogous in sensible properties to the common aniseed, is derived from a different plant, being the fruit of the *Illicium anisatum*, an evergreen tree growing in China, Japan, and Tartary. The fruit consists of from five to ten brownish ligneous capsules, four or five lines long, united together in the form of a star, each containing a brown shining seed. It is much used in France to flavour liquors, and the volatile oil upon which its aromatic properties depend is imported into this country from the East Indies, and sold as common oil of aniseed, to which, however, it is much superior. (*Togno and Durand.*)

Medical Properties and Uses. Anise is a grateful aromatic carminative; and like several other seeds of a similar character, is supposed to have the property of increasing the secretion of milk. It has been in use from the earliest times. In Europe it is much employed in flatulent colic, and as a corrigent of griping or unpleasant medicines; but in this country fennel-seed is usually preferred. Anise may be given bruised, or in powder, in the dose of twenty or thirty grains or more. The infusion is less efficient. The volatile oil may be substituted for the seeds in substance. Much use is made of this aromatic for imparting flavour to liquors.

ANTHEMIS. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ Senecionideæ. *De Cand.* Asteraceæ. *Lindley.*

Gen. Ch. Receptacle chaffy. Seed down none or a membranaceous margin. *Calyx* hemispherical, nearly equal. *Florets of the ray* more than five. *Willd.*

Several species of *Anthemis* have been employed in medicine. The *A. nobilis*, which is the subject of the present article, is by far the most important. The *A. Cotula* or May-weed is also recognised by the U.S. Pharmacopœia. (See *Cotula*.) The *A. Pyrethrum*, which affords the pellitory root, is among the officinal plants. (See *Pyrethrum*.) The *A. arvensis*, a native of this country and of Europe, bears flowers which have an acrid bitter taste, and possess medical properties analogous though much inferior to those of the common chamomile, for which they are said to be sometimes substituted in Germany. They may be distinguished by their want of smell. The *A. tinctoria* is occasionally employed as a tonic and vermifuge in Europe.

Anthemis nobilis. Willd. *Sp. Plant.* iii. 2180; Woodv. *Med. Bot.* p. 47. t. 19. This is an herbaceous plant with a perennial root. The stems are from six inches to a foot long, round, slender, downy, trailing, and divided into branches, which turn upwards at their extremities. The leaves are bipinnate, the leaflets small, thread-like, somewhat pubescent, acute, and generally divided into three segments. The flowers are solitary, with a yellow convex disk, and white rays. The calyx is common to all the florets, of a hemispherical form, and composed of several small imbricated hairy scales. The receptacle is convex, prominent, and furnished with rigid bristle-like *paleæ*. The florets of the ray are numerous, narrow, and terminated with three small teeth. The whole herb has a peculiar fragrant odour, and a bitter aromatic taste. The flowers only are officinal.

This plant is a native of Europe, and grows wild in all the temperate parts of that continent. It is also largely cultivated for medicinal purposes. In France, Germany, and Italy, it is generally known by the name of Roman chamomile. The flowers become double by cultivation, and in this state are usually preferred; though, as the sensible properties are found in

the greatest degree in the disk, which is not fully developed in the double flowers, the single are the most powerful, and are exclusively directed by the London and Edinburgh Colleges. It is rather, however, in aromatic flavour, than in bitterness, that the radial florets are surpassed by those of the disk. If not well and quickly dried, the flowers lose their beautiful white colour, and are less efficient as a medicine. Those which are whitest should be preferred.

Though not a native of America, chamomile grows wild in some parts of this country, and is occasionally cultivated in our gardens for family use, the whole herb being employed. The medicine, as found in our shops, consists chiefly of the double flowers, and is imported from Germany and England. From the former country are also occasionally imported, under the name of chamomile, the flowers of the *Matricaria Chamomilla*, a plant belonging to the same family with the Anthemis, and closely allied to it in sensible as well as medicinal properties. (See *Matricaria*.)

Properties. Chamomile flowers, as usually found in the shops, are large, almost spherical, of a dull-white colour, a fragrant odour, and a warmish, bitter, aromatic taste. When fresh, their smell is much stronger, and was fancied by the ancients to resemble that of the apple. Hence the name *chamæmelum*; and it is somewhat singular that the Spanish name *manzanilla* has a similar signification.* The flowers impart their odour and taste to both water and alcohol, the former of which, at the boiling temperature, extracts nearly one-fourth of their weight. They have not been accurately analyzed, but are known to contain a volatile oil, a bitter extractive matter, resin and a small quantity of tannin. The first two are probably their active ingredients. (See *Oleum Anthemidis*.)

Medical Properties and Uses. Chamomile is a mild tonic, in small doses acceptable and corroborant to the stomach, in larger quantities capable of acting as an emetic. In cold infusion it is often advantageously used in cases of enfeebled digestion, whether occurring as an original affection, or consequent upon some acute disease. It is especially applicable to that condition of general debility with languid appetite, which often attends convalescence from idiopathic fevers. As a febrifuge, it has also acquired much reputation, being frequently prescribed in remittents, when the subsidence of action between the paroxysms is so considerable as to demand the use of tonics, but is not sufficiently complete to admit of a resort to Peruvian bark or its preparations. Chamomile in substance has, in some instances, proved effectual in the treatment of intermittents; but we have so many other remedies more efficient in these cases, that it is now seldom if ever employed. The tepid infusion is very often given to promote the operation of emetic medicines, or to assist the stomach in relieving itself when oppressed by its contents. The flowers are sometimes applied externally as fomentations in cases of irritation or inflammation of the abdominal viscera, and as gentle incitants in flabby, ill-conditioned ulcers. The dose of the powder as a tonic is from half a drachm to a drachm three or four times a day, or more frequently, according to the end proposed. The infusion is usually preferred. The decoction and extract cannot exert the full influence of the medicine, as the volatile oil, upon which its virtues partly depend, is driven off at the boiling temperature.

* Chamæmelum from χαμαί on the ground, and μῆλον an apple. Manzanilla signifies a little apple.

ANTIMONIUM.

Antimony.

Stibium, *Lat.*; Antimoine, *Fr.*; Antimon, Spiessglas, *Germ.*; Antimonio, *Span., Ital.*

Antimony, in the metallic state sometimes called *regulus of antimony*, is not officinal in the British or United States Pharmacopœias; but as it enters into the composition of a number of important pharmaceutical preparations, we have thought it proper to notice it under a distinct head.

Antimony exists in nature, 1. as metallic antimony; 2. as an oxide; 3. as a sulphuret; and 4. as a sulphuretted oxide. It is found principally in France and Germany.

Extraction. All the antimony of commerce is extracted from the native sulphuret, which is by far the most abundant ore of this metal. The ore is first separated from its gangue by fusion. It is then reduced to powder, and placed on the floor of a reverberatory furnace; where it is subjected to a gentle heat, being constantly stirred about with an iron rake. The heat should not be sufficient to cause fusion. This process of roasting is known to be completed, when the matter is reduced to the state of a dull grayish-white powder, called *antimony ash*. By this treatment the antimony is sesquioxidized, and nearly all the sulphur dissipated in the form of sulphurous acid gas: a little sulphuret, however, remains undecomposed. The matter is then mixed either with tartar, or with charcoal impregnated with a concentrated solution of carbonate of soda, and the mixture heated in crucibles, placed in a melting furnace. The charcoal reduces the sesquioxide of antimony, while the alkali unites with the undecomposed sulphuret, and forms with it melted scorixæ, which cover the reduced metal and diminish its loss by volatilization. The metal obtained is then purified by a second fusion.

Antimony is imported into the United States principally from France, packed in casks. A portion is also shipped from Trieste, from Holland, and occasionally from Cadiz. The Spanish antimony is generally in the form of pigs; the French, in circular cakes of about ten inches in diameter, flat on one side and convex on the other; and the English, in cones. The French is most esteemed.

Properties, &c. The time of the discovery of antimony is not known; but Basil Valentine was the first to describe the method of obtaining it, in his work entitled *Currus Triumphalis Antimonii*, published towards the end of the fifteenth century. It is a brittle, brilliant metal, ordinarily of a lamellated texture, of a silver-white colour when pure, but bluish-white as it occurs in commerce. When rubbed between the fingers, it imparts a sensible odour. Its sp. gr. is 6·7, and its fusing point 810°, or about a red heat. On cooling after fusion, it assumes a crystalline structure, and an appearance on the surface bearing some resemblance to a fern leaf. When strongly heated it burns with the emission of white vapours, consisting of sesquioxide, formerly called *argentine flowers of antimony*. A small portion being fused, and then thrown from a moderate height upon a table, divides into numerous globules, which burn rapidly as they move along. It forms three combinations with oxygen; one oxide—sesquioxide of antimony, and two acids—antimonious and antimonie acids. Its equivalent number is 64·6; and the sesquioxide contains one and a half, antimonious acid two, and antimonie acid two and a half equiv. of oxygen. The sesquioxide will be noticed under the head of *Antimonii Oxidum*. *Ant-*

timonic acid is a lemon-coloured powder, which may be prepared by oxidizing the metal by digestion in nitric acid, and then driving off the excess of nitric acid by a heat not exceeding 600°. When exposed to a red heat, it parts with oxygen, and is converted into *antimonious acid*. This is a white powder, and, though medicinally inert, frequently forms a large proportion of the preparation called antimonial powder. (See *Pulvis Antimonialis*.)

The following table exhibits a view of the different officinal preparations of antimony:—

I. SULPHURETTED:—

1. Antimonii Sulphuretum, *U. S., Ed., Dub.*; Antimonii Sesquisulphuretum, *Lond.*
2. Antimonii Sulphuretum Præparatum, *Dub.*
3. Antimonii Sulphuretum Præcipitatum, *U. S.*; Antimonii Oxysulphuretum, *Lond.*; Antimonii Sulphuretum Aureum, *Ed.*; Sulphur Antimoniatum Fuscum, *Dub.*

II. OXIDIZED:—

1. *Sesquioxide*. Antimonii Oxidum, *Ed.*
2. *Sesquioxide*, combined with sesquichloride of antimony. Antimonii Oxydum Nitromuriaticum, *Dub.*
3. *Sesquioxide*, combined with tartaric acid and potassa. Antimonii et Potassæ Tartras, *U. S., Dub.*; Antimonii Potassio-tartras, *Lond.*; Antimonium Tartarizatum, *Ed. Dissolved in wine.* Vinum Antimonii, *U. S.*; Vinum Antimonii Potassio-tartratis, *Lond.*; Vinum Antimoniale, *Ed. Dissolved in diluted alcohol.* Liquor Tartari Emetici, *Dub. Mixed with lard.* Unguentum Antimonii, *U. S.*; Unguentum Antimonii Potassio-tartratis, *Lond.*; Unguentum Antimoniale, *Ed.*; Unguentum Tartari Emetici, *Dub.*
4. *Sesquioxide and antimonious acid*, mixed with phosphate of lime. Pulvis Antimonialis, *Ed., Dub.*; Pulvis Antimonii Compositus, *Lond.*

According to Serullas, all the antimonial preparations, except tartar emetic, and butter or sesquichloride of antimony, contain a minute portion of arsenic. Tartar emetic is an exception, because, according to this chemist, it separates entirely, in the act of crystallizing, from any minute portion of arsenic in the materials from which it is prepared; the poisonous metal being left behind in the mother-waters of the process.

In Pharmacy, antimony is scarcely used in the metallic state; the sulphuret being the source, either directly or indirectly, of all its medicinal preparations. (See *Antimonii Sulphuretum*.)

B.

ANTIMONII SULPHURETUM. *U. S., Ed., Dub.*

Sulphuret of Antimony.

“Native Sesquisulphuret of Antimony, purified by fusion.” *U. S.*

Off. Syn. ANTIMONII SESQUISULPHURETUM. *Lond.*

Artificial sulphuret of antimony; Antimoine sulphuré, *Fr.*; Schwefelantimon, Schwefelspiessglas, *Germ.*; Solfuro d'antimonio, *Ital.*; Antimonio crudo, *Span.*

Preparation, &c. The officinal sulphuret of antimony of the Pharmacopœias is obtained from the native sulphuret, technically called *antimony ore*, by different processes of purification; the following being an outline of that generally pursued. The ore is placed in melting pots with perforated

bottoms, which are made to rest on others, half buried in the earth. The melting pots are surrounded with wood, which is set on fire. The sulphuret is quickly melted, and runs down into the receiving pots, leaving the stony and earthy impurities behind. A better process is to connect the melting pots, by means of curved earthen tubes, with the receiving pots, placed outside the furnace. This arrangement affords facilities for removing the residue of the operation, and allows of the collection of the melted sulphuret, without interrupting the fire, and, consequently, without loss of time or fuel.

Properties, &c. Sulphuret of antimony is mostly prepared in France and Germany, and comes to the United States principally from France. It is called, in commerce, antimony, or *crude antimony*, and occurs in fused roundish masses, denominated loaves. These are dark-gray externally, and exhibit internally, when broken, a brilliant steel-gray colour, and a striated crystalline texture. Their goodness depends upon their compactness and weight, and the largeness and distinctness of the fibres. The quality of the sulphuret cannot well be judged of, except in mass; hence it ought never to be bought in powder. It is entirely soluble in muriatic acid by the aid of heat, with the evolution of sulphuretted hydrogen. The muriatic solution, when added to water, lets fall the greater part of the antimony as a white powder (*oxychloride of antimony*). If the muriatic acid should have dissolved some lead or copper, the filtered solution, after the precipitation of the white powder, would give a dark coloured precipitate with sulphuretted hydrogen; but if these metals should be absent, it would yield, with the same test, an orange-coloured precipitate, derived from a small quantity of antimony, not thrown down by the water. Arsenic may be detected by the usual tests for that metal. (See *Acidum Arseniosum*.)

Composition. Sulphuret of antimony is a sesquisulphuret, consisting of one equivalent of antimony 64·6, and one and a half equiv. of sulphur $24 \cdot 15 = 88 \cdot 75$.

Sulphuret of antimony requires to be levigated in order to fit it for exhibition as a medicine, when it takes the name of *prepared sulphuret of antimony*. In this form it is now officinal only with the Dublin College. (See *Antimonii Sulphuretum Præparatum*.)

APOCYNUM ANDROSÆMIFOLIUM. *U. S. Secondary.*

Dog's-bane.

“The root of *Apocynum androsæmifolium*.” *U. S.*

APOCYNUM. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Apocynaceæ.

Gen. Ch. *Calyx* very small, five-cleft, persistent. *Corolla* campanulate, half five-cleft, lobes revolute, furnished at the base with five dentoid glands alternating with the stamens. *Anthers* connivent, sagittate, cohering to the stigma by the middle. *Style* obsolete. *Stigma* thick and acute. *Follicles* long and linear. *Seed* comose. *Nuttall.*

Apocynum androsæmifolium. Willd. *Sp. Plant.* i. 1259; Bigelow, *Am. Med. Bot.* ii. 148. Dog's-bane is an indigenous, perennial, herbaceous plant, from three to six feet in height, and abounding in a milky juice, which exudes when any part of the plant is wounded. The stem is erect,

smooth, simple below, branched above, usually red on the side exposed to the sun, and covered with a tough fibrous bark. The leaves are opposite, petiolate, ovate, acute, entire, smooth on both sides, and two or three inches long. The flowers are white, tinged with red, and grow in loose, nodding, terminal or axillary cymes. The peduncles are furnished with very small acute bractes. The tube of the corolla is longer than the calyx, and its border spreading. The fruit consists of a pair of long, linear, acute follicles, containing numerous imbricated seeds, attached to a central receptacle, and each furnished with a long seed-down.

The plant flourishes in all parts of the United States, from Canada to Carolina. It is found along fences and the skirts of woods, and flowers in June and July. The root is the part employed.

This is large, and like other parts of the plant contains a milky juice. Its taste is unpleasant and intensely bitter. Bigelow inferred from his experiments that it contained bitter extractive, a red colouring matter soluble in water and not in alcohol, caoutchouc, and volatile oil.

Medical Properties. The powder of the recently dried root acts as an emetic in the dose of thirty grains; and is said to be sometimes employed by practitioners in the country for this purpose. By Dr. Zollickoffer it is considered a useful tonic, in doses of from ten to twenty grains. Dr. Bigelow states that its activity is diminished, and eventually destroyed by keeping. It is among the remedies employed by the Indians in lues venerea. W.

APOCYNUM CANNABINUM. U. S. Secondary.

Indian Hemp.

“The root of *Apocynum cannabinum*.” U. S.

APOCYNUM. See APOCYNUM ANDROSÆMIFOLIUM.

Apocynum cannabinum. Willd. *Sp. Plant.* i. 1259; Knapp, *Am. Med. Rev.* iii. 197. In general appearance and character, this species bears a close resemblance to the preceding. The stems are herbaceous, erect, branching, of a brown colour, and two or three feet in height; the leaves are opposite, oblong-ovate, acute at both ends, and somewhat downy beneath; the cymes are paniculate, many-flowered, and pubescent; the corolla is small and greenish, with a tube not longer than the calyx, and with an erect border; the internal parts of the flower are pinkish or purple. The plant grows in similar situations with the *A. androsæmifolium*, and flowers about the same period. Like that species, it abounds in a milky juice, and has a tough fibrous bark, which, by maceration, affords a substitute for hemp. From this circumstance the common name of the plant was derived. Its fruit is similar to that of the former species.

The root, which is the official part, is horizontal, five or six feet in length, about one-third of an inch thick, dividing near the end into branches which terminate abruptly, of a yellowish-brown colour when young, but dark chestnut when old, of a strong odour, and a nauseous, somewhat acrid, permanently bitter taste. The internal or ligneous portion is yellowish-white, and less bitter than the exterior or cortical part. The fresh root, when wounded, emits a milky juice, which concretes into a substance closely resembling caoutchouc. In the dried state, it is brittle and readily pulverized, affording a powder like that of ipecacuanha. According to Dr. Knapp* it contains a bitter principle, extractive, tannin, gallic acid, resin,

* See an Inaugural Dissertation by M. L. Knapp, M. D., in the American Med. Review, Philadelphia, 1826. Vol. iii. p. 197.

wax, caoutchouc, fecula, lignin, and a peculiar principle upon which its activity depends, and which he proposes to call *apocynin*. Dr. Griscom by a subsequent analysis obtained similar results, with the addition of gum to the other ingredients. The root yields its virtues to water and alcohol, but, according to Dr. Griscom, most readily to the former.

Medical Properties and Uses. Indian Hemp is powerfully emetic and cathartic, sometimes diuretic, and like other emetic substances, promotes diaphoresis and expectoration. It produces much nausea, diminishes the frequency of the pulse, and appears to induce drowsiness independently of the exhaustion consequent upon vomiting. The disease in which it has been found most beneficial is dropsy. An aggravated case of ascites, under the care of the late Dr. Joseph Parrish, was completely cured by the decoction of the plant, which acted as a powerful hydragogue cathartic. Dr. Knapp also found it useful in a case of dropsy. Other instances of its efficacy in this complaint have been published by Dr. Griscom of New York. (*Am. Journ. of Med. Sciences*, xii. 55.)

From fifteen to thirty grains of the powdered root will generally produce copious vomiting and purging. The decoction is a more convenient form for administration. It may be prepared by boiling half an ounce of the dried root in a pint and a half of water to a pint, of which from one to two fluid-ounces may be given two or three times a day, or more frequently if requisite. The watery extract, in doses of three or four grains three times a day, will generally act on the bowels. W.

AQUA. U.S., *Ed.*

Water.

“Natural water in the purest attainable state.” U.S. “Spring Water.”

Ed.

Eng. Gr.; Eau, Fr.; Wasser, Germ.; Acqua, Ital.; Agua, Span.

Water has always been included, as an officinal, in the United States Pharmacopœia, on account of its great importance as a medical and pharmaceutical agent. It was not admitted into the officinal lists of the British Pharmacopœias until the year 1839, when it was first recognised by the Edinburgh College. It is one of the most abundant productions in nature, and plays an important part in the economy of the universe. It is more or less concerned in almost all the changes which take place in inorganic matter, and is essential to the growth and existence of living beings, whether animal or vegetable. In treating of a substance of such diversified agency, our limits will only allow of a sketch of its properties and modifications. We shall speak of it under the several heads of *pure water*, *common water*, and *mineral waters*.

PURE WATER. Water, in a pure state, is a transparent liquid, without colour, taste, or smell. Its sp. gr. is assumed to be unity, and forms the term of comparison for that of all solids and liquids. A cubic inch of it, at the temp. of 60°, weighs very nearly 252.5 grains. It is compressible to a small extent, as was proved first by Canton, and afterwards, in an incontestable manner, by Perkins. Reduced in temp. to 32°, it becomes a solid or ice; and raised to 212°, an elastic fluid called steam. In the state of steam its bulk is increased nearly 1700 fold, and its sp. gr. so far diminished as not to be much more than half that of atmospheric air. At the temp. of 39° its density is at the maximum; and consequently, setting out from that point, it is increased in bulk by being either heated or cooled.

It has the power of dissolving more or less of all the gases, including common air, the constituents of which are always present in natural water. It is uniformly present in the atmosphere, in the form of an invisible vapour, even in the driest weather, and exerts, by its variable amount at different times, an important influence on the animal economy.

Water unites with other bodies either in the liquid or solid form; in the former case producing solutions, in the latter hydrates. It is the most universal solvent known, and on this property mainly depends its great influence in the operations of nature.

Water consists of one equivalent of hydrogen 1, and one of oxygen 8=9; or in volumes, of one volume of hydrogen and half a volume of oxygen, condensed into one volume of aqueous vapour or steam. On these data, it is easy to calculate the sp. gr. of steam; for its density will be 0.0689 (sp. gr. of hydrogen) + 0.5512 (half the sp. gr. of oxygen) = 0.6201.

COMMON WATER. From the extensive solvent powers of water, it is obvious that, in its natural state, it must be more or less contaminated with foreign matter. This is found to be the case; and, according to the nature of the strata through which it precolates, it becomes variously impregnated. When the foreign substances present are in so small amount as not very materially to alter its taste and other sensible qualities, it constitutes the different varieties of *common water*.

Common water possesses almost innumerable shades of difference, as obtained from different localities and sources, but all its varieties may be conveniently arranged under the two heads of soft and hard. A *soft water* is one which contains but inconsiderable impurities, and which, when used in washing, forms a lather with soap. By a *hard water* is understood a variety of water which contains sulphate of lime, and, therefore, curdles soap, and is unfit for domestic purposes. Tincture of soap is a convenient and useful test for ascertaining the quality of water. In distilled water it produces no effect; in soft water, only a slight opalescence; and in hard water, a milky appearance. This latter appearance is due to the formation of an insoluble compound between the oil of the soap and the lime of the sulphate of lime.

The most usual foreign substances in common water, besides oxygen and nitrogen, and matters held in a state of mechanical suspension, are carbonic acid, sulphate and carbonate of lime, and chloride of sodium (common salt). Carbonic acid is detected by lime-water, which produces a precipitate before the water is boiled, but not afterwards, as ebullition drives off this acid. The presence of sulphate of lime is shown by precipitates being produced by nitrate of baryta, and, after ebullition, by oxalate of ammonia. The first test shows the presence of sulphuric acid, and the latter indicates lime not held in solution by carbonic acid. Carbonate of lime can be present only by being held in solution by an excess of carbonic acid, and is detected by boiling the water, which causes it to precipitate. Nitrate of silver will produce a precipitate, if any soluble chloride be present; and in all ordinary cases the particular one present may be assumed to be common salt.

It is generally supposed that the oxygen and nitrogen present in natural waters are in the same proportion as in atmospheric air; but for the most part the oxygen is in larger proportion. In atmospheric air, the oxygen amounts to 20 per cent. in volume, but the usual gaseous mixture expelled from fresh water by boiling, contains about 32 per cent. of this gas. The cause of this difference in proportion, is that water has a greater affinity for oxygen than for nitrogen, and consequently takes up proportionably more of the former than of the latter from the atmosphere.

Common water is also divided into varieties according to its source. Thus we have Rain, Snow, Spring, River, Well, Lake, and Marsh Water. This division is not so practical, however, as that into *soft* and *hard*; as the source of the water is not always indicative of its quality. We shall notice these varieties in a general manner.

Rain and *snow waters* are the purest kinds of natural water, being, in effect, produced by a kind of natural distillation. Rain water, to be obtained as pure as possible, must be collected in large vessels in the open fields at a distance from houses, and some time after the rain has commenced falling; otherwise it will be contaminated with the dust which floats in the atmosphere, and other impurities derived from roofs. It may be obtained tolerably pure, even in large cities, by taking advantage of a heavy rain, and, after it has descended for a considerable time and washed away every impurity, collecting it as it falls from the roofs and spouts.

Rain water ordinarily contains atmospheric air; and, according to Liebig, a little nitric acid, if it descended during a storm. Snow water has a peculiar taste, which was formerly supposed to depend on the presence of air more oxygenous than that of the atmosphere; but in point of fact, when newly melted it contains no air, and this accounts for its vapid taste. After exposure to the air, however, for some time, it takes up the constituent gases of the atmosphere like other natural waters. Both rain and snow water are sufficiently pure for employment in most chemical operations.

Spring water (aqua fontana) depends entirely for its quality on the strata through which it flows, being purest when it passes through sand or gravel. It almost always contains a trace of common salt, and generally other impurities, which vary according to the locality of the spring.

River water (aqua fluvialis), generally speaking, is less impregnated with saline matter than spring water, on account of its being made up in considerable part of rains, and of its volume bearing so large a proportion to the surface of its bed. On the other hand, it is much more apt to have mechanically suspended in it, certain insoluble matters of a vegetable and earthy nature, which impair its transparency.

Well water, like that from springs, is liable to contain various impurities. As a general rule, the purity of the water of a well will be in proportion to its depth; and the constancy with which it is used. The Artesian or over-flowing wells, on account of their great depth, generally afford a very pure water.

Lake water cannot be characterized as having any invariable qualities. In most of the lakes in the United States it constitutes a very pure and wholesome water. This remark is particularly applicable to our great lakes.

Marsh water is generally stagnant, and contains vegetable remains undergoing decomposition. It is an unwholesome water, and ought never to be used for medicinal purposes.

The term *Aqua*, in the U. S. Pharmacopœia, may be considered as designating any natural water of good quality. In the Edinburgh Pharmacopœia it means spring water, "so far at least free of saline matter as not to possess the quality of hardness, or contain above a 6000th of solid matter." A good water may be known by its being lively, limpid, and without smell. It answers well for the cooking of vegetables, and does not curdle soap. Upon the addition of nitrate of baryta, nitrate of silver, or oxalate of ammonia, its transparency is but slightly affected; and upon being evaporated to dryness, it leaves but an inconsiderable residue.

Water should never be kept in leaden cisterns, on account of the risk of its dissolving a small portion of lead. This risk is greater in proportion to

the original purity of the water; for it is found that the presence of a minute portion of saline matter, as for example of a chloride or sulphate, protects the water from the slightest metallic impregnation. The protection is afforded by the formation of an insoluble film on the surface of the lead, as a consequence of the decomposition of the saline matter. (See *Christison on Poisons*.)

The Schuylkill water, introduced into this city, possesses all the characteristics of a good water, except that it is occasionally turbid after heavy rains. Accordingly, it may be used pharmaceutically in all cases in which "water" is directed as contra-distinguished from "distilled water." A brackish or hard water ought never to be employed. For some pharmaceutical processes, however, no natural water is deemed sufficiently pure; and hence the necessity of resorting to a process for its purification. This is effected by distillation, and accordingly all the Pharmacopœias give a formula for distilled water. (See *Aqua Destillata*.)

MINERAL WATERS. When natural waters are so far impregnated with foreign substances as to have a decided taste and a peculiar operation on the animal economy, they are called *Mineral Waters*. These are conveniently arranged for description under the four heads of *carbonated*, *sulphuretted*, *chalybeate*, and *saline*, according to the qualities which may be supposed to predominate in each.

1. *Carbonated waters* are characterized by containing an excess of carbonic acid, which gives them a sparkling appearance, and the power of reddening litmus paper. These waters frequently contain the carbonates of lime, magnesia, and iron, which are held in solution by the excess of carbonic acid. The waters of Seltzer, Spa, and Pyrmont in Europe, and of the sweet springs in Virginia, belong to this class.

2. *Sulphuretted waters* are such as contain sulphuretted hydrogen, and are distinguished by the peculiar fetid smell of that gas, and by their yielding a brown precipitate with the salts of lead or silver. Examples of this kind of mineral water are furnished by the waters of Aix la Chapelle and Harrowgate in Europe, and those of the white, red, and salt sulphur springs in Virginia.

3. *Chalybeate waters* are characterized by a strong inky taste, and by striking a black colour with the infusion of galls, and a blue one with ferrocyanuret of potassium. The iron is generally in the state of carbonate of the protoxide, held in solution by excess of carbonic acid. By standing, the carbonic acid is given off, and the protoxide, by absorbing oxygen, is precipitated as a hydrated sesquioxide of an ochreous colour. The principal chalybeate waters are those of Tunbridge and Brighton, in England, and of Bedford, Pittsburg, and Brandywine, in the United States.

4. *Saline waters* are those, the predominant properties of which depend upon saline impregnation. The salts most usually present are the sulphates and carbonates of lime, magnesia, and soda, and the chlorides of calcium, magnesium, and sodium. Potassa is occasionally present, and lithia has been detected by Berzelius in the spring of Carlsbad, in Germany. Bromine exists in considerable quantity in the saline at Theodorshalle, in Germany, and iodine is not unfrequently present. The mineral springs at Saratoga, in the state of New York, contain a small portion of iodine, and some of them a trace of bromine. The principal saline waters are those of Seidlitz in Bohemia, Cheltenham and Bath in England, and of Harrodsburg and Saratoga in the United States. To these may be added, a most important saline water, that of the ocean.

We subjoin a summary view of the composition of most of the mineral

waters enumerated under the foregoing heads, with the authority for each analysis.

1. CARBONATED.

Seltzer. In a wine pint. Carbonic acid 17 cubic inches. *Solid contents*;—carbonate of soda 4 grs.; carbonate of magnesia 5; carbonate of lime 3; chloride of sodium 17. Total 29 grs. (*Bergmann.*)

Spa. In a wine pint. Carbonic acid 13 cubic inches. *Solid contents*;—carbonate of soda 1·5 grs.; carbonate of magnesia 4·5; carbonate of lime 1·5; chloride of sodium 0·2; oxide of iron 0·6. Total 8·3 grs. (*Bergmann.*)

Pyrmont. In a wine pint. Carbonic acid 26 cubic inches. *Solid contents*;—carbonate of magnesia 10 grs.; carbonate of lime 4·5; sulphate of magnesia 5·5; sulphate of lime 8·5; chloride of sodium 1·5; oxide of iron 0·6. Total 30·6 grs. (*Bergmann.*)

2. SULPHURETTED.

Aix la Chapelle. In a wine pint. Sulphuretted hydrogen 5·5 cubic inches. *Solid contents*;—carbonate of soda 12 grs.; carbonate of lime 4·75; chloride of sodium 5. Total 21·75 grs. (*Bergmann.*)

Harrogate old well. In a wine gallon. *Gaseous contents*;—sulphuretted hydrogen 14 cubic inches; carbonic acid 4·25; nitrogen 8; carburetted hydrogen 4·15. Total 30·4 cubic inches. *Solid contents*; chloride of sodium 752 grs.; chloride of calcium 65·75; chloride of magnesium 29·2; bicarbonate of soda 12·8. Total 859·75 grs. (*English West. Quart. Journ.*)

White sulphur. In a wine gallon. *Gaseous contents*;—sulphuretted hydrogen 2·5 cubic inches; carbonic acid 2; oxygen 1·448; nitrogen 3·552. Total 9·5. *Solid contents in a pint*;—sulphate of magnesia 5·588 grs.; sulphate of lime 7·744; carbonate of lime 1·150; chloride of calcium 0·204; chloride of sodium 0·180; oxide of iron a trace; loss 0·410. Total 15·276 grs. (*Prof. William B. Rogers.*)

3. CHALYBEATE.

Tunbridge. In a wine gallon. *Solid contents*;—chloride of sodium 2·46 grs.; chloride of calcium 0·39; chloride of magnesium 0·29; sulphate of lime 1·41; carbonate of lime 0·27; oxide of iron 2·22; traces of manganese, vegetable fibre, silica, &c. 0·44; loss 0·13. Total 7·61 grs. (*Scudamore.*)

Brighton. In a wine pint. Carbonic acid 2·5 cubic inches. *Solid contents*;—sulphate of iron 1·80 grs.; sulphate of lime 4·09, chloride of sodium 1·53; chloride of magnesium 0·75; silica 0·14; loss 0·19. Total 8·5 grs. (*Marcet.*)

Cheltenham, (chalybeate.) In a wine pint. *Gaseous contents*;—carbonic acid 2·5 cubic inches. *Solid contents*;—carbonate of soda 0·5 grs.; sulphate of soda 22·7; sulphate of magnesia 6; sulphate of lime 2·5; chloride of sodium 41·3; oxide of iron 0·8. Total 73·8 grs. (*Brande and Parkes.*)

Bedford. Anderson's Spring. In a wine gallon. Carbonic acid 74 cubic inches. *Solid contents*;—sulphate of magnesia 80 grs.; sulphate of lime 14·5; chloride of sodium 10; chloride of calcium 3, carbonate of iron 5; carbonate of lime 8. Total 120·5 grs. (*Church.*)

4. SALINE.

Seidlitz. In a wine pint. *Solid contents*;—carbonate of magnesia 2·5 grs.; carbonate of lime 0·8; sulphate of magnesia 180; sulphate of lime 5; chloride of magnesium 4·5. Total 192·8 grs. (*Bergmann.*)

Cheltenham, (pure saline.) In a wine pint. *Solid contents*;—sulphate of soda 15 grs.; sulphate of magnesia 11; sulphate of lime 4·5; chloride of sodium 50. Total 80·5 grs. (*Parkes and Brande.*)

Bath. In a wine pint. Carbonic acid 1·2 cubic inches. *Solid contents*;—

carbonate of lime 0·8 grs.; sulphate of soda 1·4; sulphate of lime 9·3; chloride of sodium 3·4; silica 0·2; oxide of iron a trace. Total 15·1 grs. (*Phillips*.)

Balston Spa. Sans Souci Spring. In a wine gallon. *Solid contents*;—chloride of sodium 143·733 grs.; bicarbonate of soda 12·66; bicarbonate of magnesia 39·1; carbonate of lime 43·407; carbonate of iron 5·95; iodide of sodium 1·3; silica 1. Total 247·15 grs. (*Steel*.)

Saratoga. Iodine Spring. In a wine gallon. *Gaseous contents*;—carbonic acid 336 cubic inches; atmospheric air 4. Total 340 cubic inches. *Solid contents*;—chloride of sodium 187 grs.; carbonate of magnesia 75; carbonate of lime 26; carbonate of soda 2; carbonate of iron 1; iodine 3·5. Total 294·5 grs. (*Prof. Emmons*.)

Saratoga. Pavilion Spring. In a wine gallon. *Gaseous contents*;—carbonic acid 359·05 cubic inches; atmospheric air 5·03. Total 364·08 cubic inches. *Solid contents*;—chloride of sodium 187·68 grs.; carbonate of soda 4·92; carbonate of lime 52·84; carbonate of magnesia 56·92; carbonate of iron 3·51; sulphate of soda 1·48; iodide of sodium 2·59; alumina 0·42; silica 1·16; phosphate of lime 0·19; bromide of potassium a trace. Total 311·71 grs. (*Dr. J. R. Chilton*.)

Saratoga. Union Spring. In a wine gallon. *Gaseous contents*;—carbonic acid 314·16 cubic inches; atmospheric air 4·62. Total 318·78 cubic inches. *Solid contents*;—chloride of sodium 243·620 grs.; carbonate of magnesia 84·265; carbonate of lime 41·600; carbonate of soda 12·800; carbonate of iron 5·452; iodide of sodium, or iodine 3·600; silica and alumina 1·570; bromide of potassium a trace. Total 392·907 grs. (*Dr. J. R. Chilton*.)

Saratoga. Congress Spring. In a wine gallon. *Gaseous contents*;—carbonic acid 311 cubic inches; atmospheric air 7. Total 318 cubic inches. *Solid contents*;—chloride of sodium 385 grs.; iodide of sodium 3·5; bicarbonate of soda 8·982; bicarbonate of magnesia 95·788; carbonate of lime 98·098; carbonate of iron 5·075; silica 1·5; bromide of potassium a trace. Total 597·943 grs. (*Steel*.)

Sea Water. English Channel. In a thousand grains. Water 964·744 grs.; chloride of sodium 27·059; chloride of potassium 0·765; chloride of magnesium 3·667; bromide of magnesium 0·029; sulphate of magnesia 2·296; sulphate of lime 1·407; carbonate of lime 0·033. Total 1000·000 grs. (*Schweitzer*.) It is perceived that bromine is present in very minute amount. 100 pounds of sea water yield only $3\frac{1}{2}$ grains of this element. According to Balard, iodine exists in the water of the Mediterranean.

Medical and Dietetic Properties of Water.—Water is a substance of the first necessity to animals and vegetables. In animals there exists an instinctive desire for it, to repair the waste of the fluids which is constantly taking place in the animal economy. It constitutes the basis of nearly all the secretions, and nine-tenths of the weight of the blood. In short, it is nature's agent for producing the liquid state, and is the only diluent proper in a state of health.

Water as a remedy is highly important, though we are apt to overlook its agency, on account of our familiarity with its use. When taken into the stomach, it acts by its temperature, by its bulk, and by being absorbed. When of the temperature of about 60°, it gives no positive sensation either of heat or cold; between 60° and 45°, it creates a cool sensation; and below 45°, a decidedly cold one. Between 60° and 100°, it relaxes the fibres of the stomach, and is apt to produce nausea, particularly if the effect of bulk be added to that of temperature. By its bulk and solvent powers, it

often allays irritation by diluting the acrid contents of the stomach and bowels, and favouring their final expulsion; and by its absorption, it promotes the secretion of urine and cutaneous transpiration. Indeed, its influence is so great in the latter way, that it may be safely affirmed, that sudorifics and diuretics will not produce their proper effect unless assisted by copious dilution.

Water, externally applied as a bath, is also an important remedy. It may act by its own specific effects as a liquid, or as a means of modifying the heat of the body. It acts in the latter way differently, according to the particular temperature at which it may be applied. When this is above 97° , it constitutes either the vapour or hot bath; when between 97° and 85° , the warm bath; between 85° and 65° , the tepid bath; and between 65° and 32° , the cold bath.

The general action of the *vapour bath* is to accelerate the circulation, and produce profuse sweating. It acts locally on the skin by softening and relaxing its texture. In stiffness of the joints, and various diseases of the skin, it has often proved beneficial. The late Dr. Duncan had seen scaly cutaneous diseases, which had resisted for years every other treatment, become quickly cured by its use.

The *hot bath*, like the vapour bath, is decidedly stimulant. By its use, the pulse becomes full and frequent, the veins turgid, the face flushed, the skin red, and the respiration quickened. If the temperature be high, and the constitution peculiar, its use is not without danger; as it is apt to produce a feeling of suffocation, violent throbbing in the temples, and vertigo, with tendency to apoplexy. When it acts favourably, it depletes actively from the skin by producing profuse sweating.

The *warm bath*, though below the animal heat, nevertheless produces a sensation of warmth; as its temperature is above that of the surface. It diminishes the frequency of the pulse, especially if previously accelerated, renders the respiration slower, lessens the heat of the body, and relaxes the skin. The warm bath cannot be deemed, strictly speaking, a stimulant. By relieving certain diseased actions and states, accompanied by morbid irritability, it often acts as a soothing remedy, producing a disposition to sleep. It is proper in febrile and exanthematous diseases, in which the pulse is frequent, and the skin preternaturally hot and dry, and where the general condition is characterized by restlessness. It is contra-indicated in diseases of the head and chest.

The *tepid bath*, from its temperature, is not calculated to have much modifying influence on the heat of the body. Its peculiar effects are to soften and cleanse the skin, and promote insensible perspiration.

The *cold bath* acts differently according to its temperature and manner of application, and the condition of the system to which it is applied. When of low temperature and suddenly applied, it acts primarily as a stimulant, by the sudden and rapid manner in which the caloric is abstracted, or made to pass out of the body; next, as a tonic, by condensing the living fibre; and finally, as a sedative. If the cold bath were applied at a temperature just sufficient to excite a cool sensation, and this temperature were gradually and imperceptibly lowered, it is probable that it would act exclusively as a sedative.

From the above explanations, it may be easily understood that the cold bath will act very differently under different circumstances. It is often useful in diseases of relaxation and debility, when practised by affusion or plunging. But it is essential to its efficacy and safety in these cases, that the stock of vitality should be sufficient to create, immediately after its use,

those general sensations of warmth and invigoration included under the term reaction. It has also been used with advantage by the late Dr. Currie of Liverpool, in the form of affusion, in certain febrile diseases, especially scarlatina. To make it safe, however, the heat must be steadily above the natural standard, and the patient must be free from all sense of chilliness, and not in a state of profuse perspiration.

Cold water is frequently applied as a sedative in local inflammations, and as a means of restraining hemorrhage. Its use, however, is inadmissible in inflammations of the chest.

Pharm. Uses. Water is the most extensive pharmaceutical agent that we possess. It is employed in a vast number of preparations, as a means of promoting chemical action by its solvent powers. It is more or less present in all the liquid forms of medicines, and is the sole menstruum in the medicated waters, decoctions, and infusions.

ARALIA NUDICAULIS. *U. S. Secondary.*

False Sarsaparilla.

“The root of *Aralia nudicaulis*.” *U. S.*

ARALIA. Sex. Syst. Pentandria Pentagynia.—*Nat. Ord.* Araliaceæ.

Gen. Ch. Flowers umbelled. *Calyx* five-toothed, superior. *Petals* five. *Stigma* sessile, subglobose. *Berry* five-celled, five-seeded. *Torrey.*

Aralia nudicaulis. Willd. *Sp. Plant.* i. 1521; Rafinesque, *Med. Flor.* i. 53. The false sarsaparilla, wild sarsaparilla, or small spikenard, as this plant is variously called, is an indigenous perennial, with one leaf and one flower-stem springing together from the root or from a very short stalk, and seldom rising two feet in height. The leaf, which stands upon a long foot-stalk, is twice ternate, or once and quinate, with oblong-oval, acuminate leaflets, rounded at the base, serrate on the margin, and smooth on both surfaces. The scape or flower-stem is naked, shorter than the leaf, and terminated by three small umbels, each consisting of from twelve to thirty small yellowish or greenish flowers. The fruit consists of small round berries, about as large as those of the common elder.

The plant grows throughout the United States, from Canada to Carolina, inhabiting shady and rocky woods, and delighting in a rich soil. It flowers in May and June. The root is the officinal portion.

This is horizontal, creeping, sometimes several feet in length, about as thick as the little finger, more or less twisted, externally of a yellowish-brown colour, of a fragrant odour, and a warm, aromatic, sweetish taste. It has not been analyzed.

Medical Properties and Uses. False sarsaparilla is a gentle stimulant and diaphoretic, and is thought to exert an alterative influence over the system analogous to that of the root from which it derived its common name. It is used in domestic practice, and by some practitioners in the country, as a remedy in rheumatic, syphilitic, and cutaneous affections, in the same manner and dose as the genuine sarsaparilla.

The root of the *Aralia racemosa* or *American spikenard*, though not officinal, is used for the same purposes as the *A. nudicaulis*, which it is said to resemble in medical properties. Dr. Peck strongly recommends the root of the *Aralia hispida*, called in Massachusetts *dwarf elder*, as a diuretic in dropsy. He uses it in the form of decoction, and finds it pleasanter to the taste and more acceptable to the stomach than most other medicines of the same class. (*Am. Journ. of Med. Sci.* xix. 117.)

W.

ARALIA SPINOSA. U. S. Secondary.

Angelica-tree Bark.

“The bark of *Aralia spinosa*.” U. S.

ARALIA. See ARALIA NUDICAULIS.

Aralia spinosa. Willd. *Sp. Plant.* i. 1520. This is an indigenous arborescent shrub, variously called *angelica-tree*, *toothach tree*, and *prickly ash*. The last name, however, should be dropped, as it belongs properly to the *Xanthoxylum fraxineum*, and if retained might lead to confusion. The stem is erect, simple, from eight to twelve feet high, armed with numerous prickles, and furnished near the top with very large bipinnate or tripinnate leaves, which are also prickly, and are composed of oval, pointed, slightly serrate leaflets. It terminates in an ample panicle, very much branched, and bearing numerous small hemispherical umbels, in each of which are about thirty white flowers.

This species of *Aralia* is found chiefly in the Southern and Western States, though cultivated in the gardens of the north as an ornamental plant. It flourishes in low, fertile woods, and flowers in August and September. The bark, root, and berries are medicinal; but the first only is directed by the Pharmacopœia.

The bark is thin, grayish externally, yellowish within, of an odour somewhat aromatic, and a bitterish, pungent, acrid taste. It yields its virtues to boiling water.

Medical Properties and Uses. The virtues of *Aralia spinosa* are those of a stimulant diaphoretic. According to Elliot, an infusion of the recent bark of the root is emetic and cathartic. The remedy is used in chronic rheumatism and cutaneous eruptions. Pursh states, that a vinous or spirituous infusion of the berries is remarkable for relieving rheumatic pains; and a similar tincture is said to be employed in Virginia with advantage in violent colic. The pungency of this tincture has also been found useful in relieving toothach.

The bark is most conveniently administered in decoction.

ARCTIUM LAPPA. Semina. Radix. Dub.

Seeds and Root of Burdock.

Bardane, Fr.; Gemeine Klette, Germ.; Bardana, Ital., Span.

ARCTIUM. *Sex. Syst.* Syngenesia Æqualis.—*Nat. Ord.* Compositæ-Cinareæ, De Cand. Cynaraceæ, Lindley.

Gen. Ch. Receptacle chaffy. *Calyx* globular; the scales at the apex with inverted hooks. *Seed-down* bristly, chaffy. Willd.

Arctium Lappa. Willd. *Sp. Plant.* iii. 1631; Woodv. *Med. Bot.* p. 32. t. 13.—*Lappa minor*. De Cand. *Prodrom.* vi. 661. The *burdock* is a biennial plant, with a simple spindle-shaped root, a foot or more in length, brown externally, white and spongy within, furnished with threadlike fibres, and having withered scales near the summit. The stem is succulent, pubescent, branching, and three or four feet in height, bearing very large cordate, denticulate leaves, which are green on their upper surface, whitish and downy on the under, and stand on long footstalks. The flowers are purple, globose, and arranged in terminal panicles. The calyx consists of imbricated scales, with hooked extremities, by which they adhere to clothes,

and the coats of animals. The seed-down is rough and prickly, and the seeds are quadrangular.

This plant is a native of Europe, and is abundant in the United States, where it grows on the roadsides, among rubbish, and in cultivated grounds. Pursh thinks that it was introduced. The root, which should be collected in spring, loses four-fifths of its weight by drying.

The odour of the root is weak and unpleasant, the taste mucilaginous and sweetish, with a slight degree of bitterness and astringency. Among its constituents, inulin has been found by Guibourt, and sugar by Fée.

The seeds are aromatic, bitterish, and somewhat acrid.

Medical Properties and Uses. The root is considered aperient, diaphoretic, and sudorific, without irritating properties; and has been recommended in gouty, scorbutic, venereal, rheumatic, scrofulous, leprosy, and nephritic affections. To prove effectual, its use must be persevered in for a long time. It is best administered in the form of decoction, which may be prepared by boiling two ounces of the recent bruised root in three pints of water to two, and given in the quantity of a pint during the day. The seeds are diuretic, and have been used in the same complaints in the form of emulsion or powder. The dose is a drachm. The leaves have also been employed both externally and internally in cutaneous eruptions and ulcerations.

W.

ARGENTUM. *U. S., Lond., Ed., Dub.*

Silver.

Argent, Fr.; Silber, Germ.; Argento, Ital.; Plata, Span.

Silver is occasionally found in the metallic state, sometimes pure and crystallized or in the form of vegetations, at other times combined with gold, antimony, arsenic, or mercury; but more usually it occurs in the state of sulphuret, either pure, or mixed with other sulphurets, such as those of copper, lead, and antimony. It is sometimes, though rarely, found as a chloride.

The most productive mines of silver are found on this continent, being those of Mexico and Peru; the richest in Europe are situated at Kongsberg in Norway, in Hungary, and in Transylvania. The principal ore which is worked is the sulphuret. The mineral containing silver which is most disseminated is argentiferous galena, which is a sulphuret of lead, associated with sulphuret of silver. No mines of silver have been found in the United States; but argentiferous galena exists in several localities.

Extraction. Silver is extracted from its ores by two principal processes, *amalgamation* and *cupellation*. At Freyberg in Saxony, the ore, which is principally the sulphuret, is mixed with a tenth of chloride of sodium (common salt), and roasted in a reverberatory furnace. The sulphur becomes acidified, and combines with sodium and oxygen, so as to form sulphate of soda, while the chlorine forms a chloride with the silver. The roasted mass is then reduced to very fine powder, mixed with half its weight of mercury, one-third of its weight of water, and about a seventeenth of iron in flat pieces, and subjected, for sixteen or eighteen hours, to constant agitation in barrels turned by machinery. The chlorine combines with the iron, and remains in solution as chloride of iron, while the silver forms an amalgam with the mercury. The amalgam is then subjected to pressure in leathern bags, through the pores of which the excess of mercury passes, a solid amalgam being left behind. This is then subjected to heat in a distillatory

apparatus, by means of which the mercury is separated from the pure silver, which remains behind in the form of a porous mass. In Peru and Mexico the process is somewhat similar to the above, common salt and mercury being used; but slaked lime and sulphuret of iron are also employed, with an effect which is not very obvious.

When argentiferous galenas are worked for the silver they contain, they are first reduced, and the argentiferous lead obtained is fused on a large shallow *cupel* called a test, and exposed to the blast of a bellows, whereby the lead is oxidized, half vitrified, and driven off the test in scales, forming the substance called *litharge*. By continuing the operation, the whole of the lead is separated, and the silver, not being oxidizable, remains behind as a brilliant fused mass. The time required for the separation is much abridged by the process of Mr. Pattinson of Newcastle. This consists in allowing the melted alloy to cool slowly, and separating the crystals which first form, and which are much richer in silver than the original mass, by means of a perforated ladle. The crystals are then subjected to cupellation, for the separation of the small proportion of lead which they still contain.

Properties Silver is a white metal, very brilliant, tenacious, malleable, and ductile. In malleability and ductility, it is inferior only to gold. It is harder than gold, but softer than copper. Its equivalent number is 108, and its sp. gr. about 10.4. Exposed to a full red heat, it enters into fusion, and exhibits a brilliant appearance. It is not oxidized in the air, but contracts a superficial tarnish of sulphuret of silver by the action of sulphuretted hydrogen, which always exists in minute quantity in the atmosphere. It is entirely soluble in diluted nitric acid. If any gold be present, it will remain undissolved as a dark-coloured powder. From the nitric solution, the whole of the silver may be thrown down by chloride of sodium, as a white precipitate of chloride of silver, characterized by being totally soluble in ammonia. If the remaining solution should contain copper or lead, it will be precipitated or discoloured by sulphuretted hydrogen.

Pharm. Uses. Silver has no action on the animal economy in the metallic state. The only officinal preparations containing it are the *nitrate* and *cyanuret*. The *oxide* and *chloride* have been proposed as medicines, and will be noticed in the Appendix.

ARMORACIA. *U. S., Lond., Ed.*

Horse-radish.

“The fresh root of *Cochlearia Armoracia*.” *U. S., Ed.* “*Cochlearia Armoracia. Radix recens.*” *Lond.*

Off. Syn. COCHLEARIA ARMORACIA. Radix. *Dub.*

Raifort sauvage, *Fr.*; Meerrettig, *Germ.*; Rafano rusticano, *Ital.*; Rabano rusticano, *Span.*

COCHLEARIA. *Sex. Syst.* Tetradynamia Siliculosa.—*Nat. Ord.* Brassicaceæ or Cruciferae.

Gen. Ch. *Silicula* emarginate, turgid, scabrous, with gibbous, obtuse valves. *Willd.*

Cochlearia Armoracia. Willd. *Sp. Plant.* iii. 451; Woodv. *Med. Bot.* p. 400. t. 145. The root of this plant is perennial, sending up numerous very large leaves, from the midst of which a round, smooth, erect, branching stem rises two or three feet in height. The radical leaves are lance-

shaped, waved, scalloped on the edges, sometimes pinnatifid, and stand upon strong footstalks. Those of the stem are much smaller, without footstalks, sometimes divided at the edges, sometimes almost entire. The flowers are numerous, white, peduncled, and form thick clusters at the ends of the branches. The calyx has four ovate, deciduous leaves, and the corolla an equal number of obovate petals, twice as long as the calyx, and inserted by narrow claws. The pod is small, elliptical, crowned with the persistent stigma, and divided into two cells, each containing from four to six seeds.

The horse-radish is a native of western Europe, growing wild on the sides of ditches and in other moist situations. It is cultivated for culinary purposes in most civilized countries, and is said to have become naturalized in some parts of the United States. Its flowers appear in June.

The root, which is officinal in its fresh state, is long, tapering, whitish externally, very white within, fleshy, of a strong pungent odour when scraped or bruised, and of a hot, biting, somewhat sweetish taste. Its virtues are imparted to water and alcohol. They depend upon a volatile oleaginous principle, which is dissipated by drying; the root becoming at first sweetish, and ultimately insipid and quite inert. Its acrimony is also destroyed by boiling. The volatile oil may be obtained by distillation with water. It is pale yellow, heavier than water, very volatile, excessively pungent, acrid, and corrosive, exciting inflammation and even vesication when applied to the skin. It exists in exceedingly small proportion in the root, constituting, according to Gutret, only 6 parts in 10,000. Besides this principle, the fresh root contains, according to the same chemist, a minute quantity of bitter resin, sugar, extractive, gum, starch, albumen, acetic acid, acetate and sulphate of lime, water, and lignin. (*Geiger*.) It may be kept for some time without material injury, by being buried in sand in a cool place.

Medical Properties and Uses. Horse-radish is highly stimulant, exciting the stomach when swallowed, and promoting the secretions, especially that of urine. Externally applied it is a rubefacient. Its chief use is as a condiment to promote appetite, and invigorate digestion; but it is also occasionally employed as a medicine, particularly in dropsical complaints attended with an enfeebled condition of the digestive organs, and of the system in general. It has, moreover, been recommended in palsy and chronic rheumatism, both as an internal and external remedy; and in scorbutic affections is highly esteemed. Cullen found advantage in cases of hoarseness from the use of a syrup prepared from an infusion of horse-radish and sugar, and slowly swallowed in the quantity of one or two teaspoonfuls, repeated as occasion demanded. The root may be given in the dose of half a drachm or more, either grated or cut into small pieces.

ARNICA. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ-Senecionidæ. *De Cand.* Asteracæ. *Lindley.*

Gen. Ch. Calyx with equal leaflets, in a double row. Seed-down hairy, sessile. Seeds both of the disk and ray furnished with seed-down. Receptacle hairy. Hayne.

Arnica montana. Willd. *Sp. Plant.* iii. 2106; Woodv. *Med. Bot.* p. 41. t. 17. This is a perennial, herbaceous plant, having a woody, brownish, horizontal root, ending abruptly, and sending forth numerous slender fibres of the same colour. The stem is about a foot high, cylindrical, striated, hairy, and terminating in one, two, or three peduncles, each bearing a flower. The radical leaves are ovate, entire, ciliated, and obtuse; those of the stem, which usually consist of two opposite pairs, are lance-shaped. Both are of a bright green colour, and somewhat pubescent on their upper surface. The flowers are very large, and of a fine orange-yellow colour. The calyx is greenish, imbricated, with lanceolate scales. The ray consists of about fourteen ligulate florets, twice as long as the calyx, striated, three-toothed, and hairy at the base; the disk, of tubular florets, with a five-lobed margin.

This plant is a native of the mountainous districts of Europe and Siberia, and is found, according to Nuttall, in the northern regions of this continent, west of the Mississippi. It has been introduced into England, and, were there a sufficient demand for it, might no doubt be cultivated in this country; but it is very little used, and in the U. S. Pharmacopœia has been placed with the medicines not considered strictly official. The flowers, leaves, and root have been employed in medicine; but the flowers are usually preferred.

Properties. The whole plant, when fresh, has a strong disagreeable odour, which is apt to excite sneezing, and is diminished by desiccation. The taste is acrid, bitterish, and durable. Water extracts its virtues. Chevallier and Lassaigne discovered in the flowers, gallic acid, gum, albumen, yellow colouring matter, an odorous resin, and a bitter principle which they considered identical with that discovered by them in the seeds of the *Cytisus Laburnum*, and hence named *cytisin*. This substance is yellow, of a bitter and nauseous taste, deliquescent, readily soluble in water and diluted alcohol, but with difficulty in strong alcohol, and insoluble in ether. In the dose of five grains it is powerfully emetic and cathartic, and is supposed to be the active principle of the plant. The flowers are said also to contain a small proportion of a blue volatile oil. According to Pfaff, the root contains volatile oil, an acrid resin, extractive, gum, and lignin.

Medical Properties and Uses. Leopard's-bane is a stimulant, directed with peculiar energy to the brain and whole nervous system, as manifested by the headach, spasmodic contractions of the limbs, and difficulty of respiration, which result from its use. It acts also as an irritant to the stomach and bowels, often producing an emetic and cathartic effect, and is said by Bergius to be diuretic, diaphoretic, and emmenagogue. It is much used by the Germans, who prescribe the flowers and root with advantage in amaurosis, paralysis, and other nervous affections. It is said to prove serviceable in that disordered condition which succeeds concussion of the brain from falls, blows, &c.; and from this circumstance has received the title of *panacea lupsorum*. It has also been recommended in intermittent fever, dysentery, diarrhœa, nephritis, gout, rheumatism, dropsy, chlorosis, and various other complaints, in most of which it seems to have been empirically prescribed. It seems to be peculiarly useful in diseases attended with a debilitated or typhoid state of the system, to which it is adapted by its stimulant properties. The powdered leaves are sometimes employed as a sternutatory; and the inhabitants of Savoy and the Vosges are said to substitute them for tobacco. The French practitioners occasionally use the

flowers of Arnica, though much less extensively than the German. In England and the United States the medicine is little known. It is best given in substance or infusion. The dose of the powder is from five to ten grains frequently repeated. The infusion may be prepared by digesting an ounce in a pint of water, of which from half a fluidounce to a fluidounce may be given every two or three hours. It should always be strained through linen, in order to separate the fine fibres, which might otherwise irritate the throat. The poisonous properties of the plant are said to be best counteracted by the free use of vinegar or other dilute vegetable acid.

W.

ARTEMISIA SANTONICA. Semina. Dub.

Seeds of Tartarian Southernwood.

Barbotine, Semencine, *Fr.*; Wurmsame, *Germ.*; Seme Santo, *Ital.*

ARTEMISIA. See ABSINTHIUM.

The wormseed of Europe is ascribed by the Dublin College, without sufficient authority, to the *Artemisia Santonica*, or Tartarian southernwood. It is of two kinds; one called the Aleppo, Alexandria, or Levant wormseed, the other Barbary wormseed.

The former is supposed to be the product of the *Artemisia Contra*, which grows in Persia, Asia Minor, and other parts of the East. It consists in fact not of the seeds, but of the small globular unexpanded flowers of the plant, mixed with their broken peduncles, and with minute, obtuse, smooth leaves. It has a greenish colour, a very strong aromatic odour increased by friction, and a very bitter disagreeable taste.

The Barbary wormseed is thought by some to be derived from the *Artemisia Judaica*, by others from the *A. glomerata* of Sieber, both of which grow in Palestine and Arabia. It consists of broken peduncles, having the calyx sometimes attached to their extremity. The calyx is also sometimes separate, consisting of very small linear obtuse leaflets. The flowers are wanting, or in the shape of minute globular buds. All these parts are covered with a whitish down, which serves to distinguish this variety from the wormseed of the Levant. It is moreover lighter and more coloured than the latter. Its smell and taste are the same.

These products contain a volatile oil and a resinous extractive matter, to which their virtues have been ascribed. A peculiar principle has also been discovered in them, which has received the name of *santonin*. It is crystallizable, colourless, tasteless, inodorous, soluble in ether and alcohol, and nearly insoluble in water. It may be obtained by treating wormseed with hydrate of lime and alcohol, evaporating the tincture to one-quarter, filtering the residue to separate the resin, and treating it while hot with concentrated acetic acid. The santonin is deposited in crystals as the liquor cools. In the dose of three or four grains twice a day, it is said to have been found useful as a vermifuge; but the fact is very doubtful. (*Journ. de Pharm.* xvii. 115, and xx. 44.)

Medical Properties and Uses. The products above described have long been celebrated as a vermifuge, and the title of *semen contra*, by which they are designated in many works on pharmacy, originated in their anthelmintic property. They may be given in powder or infusion. The dose in substance is from ten to thirty grains, which should be repeated morning and evening for several days, and then followed by a brisk cathartic. They are not used in this country, having been superseded by the seeds of the *Chenopodium anthelminticum*, which are universally known among us by the name of wormseed.

W.

ARUM. U.S. Secondary.

Dragon-root.

"The cormus of *Arum triphyllum*." U. S.

ARUM. *Sex. Syst.* Monœcia Polyandria.—*Nat. Ord.* Araceæ.

Gen. Ch. *Spathe* one-leaved, cowled. *Spadix* naked above, female below, staminate in the middle. *Willd.*

The root, or, as it is botanically called, the cormus of the *Arum maculatum*, is occasionally used as a medicine in Europe, and held a place in the Dublin Pharmacopœia previously to the last edition. Its medicinal properties are so precisely those of the *A. triphyllum* of this country, that the substitution of the latter in our Pharmacopœia was a matter of obvious propriety, independently of the consideration that the root is efficient only in the recent state.

Arum triphyllum. Willd. *Sp. Plant.* iv. 480; Bigelow, *Am. Med. Bot.* i. 52. The *dragon-root*, *Indian turnip*, or *wake-robin*, as this plant is variously called in common language, has a perennial root or cormus, which, early in the spring, sends up a large, ovate, acuminate, variously coloured spathe, convoluted at bottom, flattened and bent over at top like a hood, and supported by an erect, round, green or purplish scape. Within the spathe is a club-shaped spadix, green, purple, black, or variegated, rounded at the end, and contracted near the base, where it is surrounded by the stamens or germs in the diœcious plants, and by both in the monœcious, the female organs being below the male. The spathe and upper portion of the spadix gradually decay, while the germs are converted into a compact bunch of shining, scarlet berries. The leaves, which are usually one or two in number, and stand on long sheathing footstalks, are composed of three ovate acuminate leaflets, paler on their under than their upper surface, and becoming glaucous as the plant advances. There are three varieties of this species of *Arum*, distinguished by the colour of the spathe, which in one is green, in another dark purple, and in a third white.

The plant is a native of North and South America, and is common in all parts of the United States, growing in damp woods, in swamps, along ditches, and in other moist shady places. All parts of it are highly acrid, but the root only is officinal.

This is roundish, flattened, an inch or two in diameter, covered with a brown, loose, wrinkled epidermis, and internally white, fleshy, and solid. In the recent state, it has a peculiar odour, and is violently acrid, producing, when chewed, an insupportable burning and biting sensation in the mouth and throat, which continues for a long time, and leaves an unpleasant soreness behind. According to Dr. Bigelow, its action does not readily extend through the cuticle, as the bruised root may lie upon the skin till it becomes dry, without producing pain or redness. The acrid principle is extremely volatile, and is entirely driven off by heat. It is not imparted to water, alcohol, ether, or olive oil. By exposing the bruised root and stalks to a boiling heat under water, Dr. Bigelow obtained small quantities of an inflammable gas. The root loses nearly all its acrimony by drying, and in a short time becomes quite inert. It contains a large proportion of starch, which may be obtained from it as white and delicate as from the potato. In Europe, the dried root of the *A. maculatum* is said sometimes to be employed by the country people, in times of great scarcity, as a substitute for bread; and an amylaceous substance is prepared from it in England, called

Portland arrowroot or *Portland sago*. For medicinal use, the Indian turnip may be preserved fresh for a year, if buried in sand. (*Thacher*.)

Medical Properties and Uses. Arum in its recent state is a powerful local irritant, possessing the property of stimulating the secretions, particularly those of the skin and lungs. It has been advantageously given in asthma, pertussis, chronic catarrh, chronic rheumatism, and various affections connected with a cachectic state of the system. As immediately taken from the ground, it is too acrid for use. The recently dried root, which retains a portion of the acrimony, but not sufficient to prevent its convenient administration, is usually preferred. It may be given in the dose of ten grains, mixed with gum arabic, sugar, and water, in the form of emulsion, repeated two or three times a day, and gradually increased to half a drachm or more. The powder made into a paste with honey or syrup, and placed in small quantities upon the tongue, so as to be gradually diffused over the mouth and throat, is said to have proved useful in the aphthous sore-mouth of children. W.

ASARUM. *Lond.*

Asarabacca.

“*Asarum europæum. Folia.*” *Lond.*

Off. Syn. ASARUM EUROPÆUM. FOLIA. *Dub.*

Asaret, Cabaret, Fr.; Haselwurz, Germ.; Asaro, Ital., Span.

ASARUM. *Sex. Syst.* Dodecandria Monogynia.—*Nat. Ord.* Aristolochiaceæ.

Gen. Ch. Calyx three or four-cleft, sitting on the germen. *Corolla* none. *Capsule* coriaceous, crowned. *Willd.*

Asarum Europæum. Willd. *Sp. Plant.* ii. 838; Woodv. *Med. Bot.* p. 170. t. 66. The *asarabacca* has a perennial root or rhizoma, with a very short, round, simple, herbaceous, pubescent stem, which in general supports only two leaves and one flower. The leaves, which are opposite and stand on long footstalks, are kidney-shaped, entire, somewhat hairy, and of a shining deep green colour. The flower is large, of a dusky purple colour, and placed upon a short terminal peduncle. The calyx, which supplies the place of a corolla, is bell-shaped, greenish at the base, and divided at the mouth into three pointed purplish segments, which are erect, and turned inwards at their extremity. The filaments are twelve, and prolonged beyond the anthers into a small hook. The style is surmounted by a six-parted reddish stigma. The fruit is a six-celled coriaceous capsule, crowned with the persistent calyx.

This species of *Asarum* is a native of Europe, growing between 37° and 60° N. latitude, in woods and shady places, and flowering in May. All parts of the plant are acrid. The leaves only are directed by the London College, but the whole plant, including root, stem, leaves, and flowers, is usually kept in the shops. The root is about as thick as a goose-quill, of a grayish colour, quadrangular, knotted and twisted, and sometimes furnished with radicles at each joint. It has a smell analogous to that of pepper, an acrid taste, and affords a grayish powder. The leaves are nearly inodorous, with a taste slightly aromatic, bitter, acrid, and nauseous. Their powder is yellowish-green. Both parts rapidly lose their activity by keeping, and ultimately become inert. Geiger, however, asserts that they keep well if perfectly dry. Their virtues are imparted to alcohol and water, but are dissipated by decoction. According to MM. Feneulle and Lassaigne, the

root contains a concrete volatile oil, a very acrid fixed oil, a yellow substance analogous to *cytisin*, starch, albumen, mucilage, citric acid, and saline matters. The latest analysis is by Gräger, who found in the *root* a liquid volatile oil, two concrete volatile substances called respectively *asarum camphor* and *asarite*, a peculiar bitter principle called *asarin*, tannin, extractive, resin, starch, gluten, albumen, lignin, citric acid, and various salts; in the *leaves*, *asarin*, tannin, extractive, chlorophylle, albumen, citric acid, and lignin. The active principles appear to be the volatile oil, which is lighter than water, glutinous, yellow, of an acrid and burning taste, and a smell like that of valerian, and the *asarin*, which is soluble in alcohol and very bitter, and is probably the same as the *cytisin* of Feneulle and Lassaigue.

Medical Properties and Uses. The root and leaves of *asarabacca*, either fresh or carefully dried, are powerfully emetic and cathartic, and were formerly much used in Europe with a view to these effects. The dose is from thirty grains to a drachm. But as an emetic they have been entirely superseded by *ipeacacuanha*, and are now used chiefly, if not exclusively, as an *errhine*. The powdered root, snuffed up the nostrils in the quantity of one or two grains, produces much irritation, and a copious flow of mucus, which is said to continue sometimes for several days. The leaves are milder and generally preferred. They should be used in the quantity of three or four grains, repeated every night until the desired effect is experienced. They have been strongly recommended in headach, chronic ophthalmia, and rheumatic and paralytic affections of the face, mouth, and throat.

Off. Prep. Pulvis Asari Compositus, *Dub.* W.

ASARUM. U.S. Secondary.

Canada Snakeroot. Wild Ginger.

“The root of *Asarum Canadense*.” U. S.

ASARUM. See ASARUM.

Asarum Canadense. Willd. *Sp. Plant.* ii. 838; Bigelow, *Am. Med. Bot.* i. 149; Barton, *Med. Bot.* ii. 85. This species of *Asarum* very closely resembles the *A. Europæum*, or *asarabacca*, in appearance and botanical character. It has a long, creeping, jointed, fleshy, yellowish root or rhizoma, furnished with radicles of a similar colour. The stem is very short, dividing, before it emerges from the ground, into two long round hairy leaf-stalks, each of which bears a broad kidney-shaped leaf, pubescent on both surfaces, of a rich shining light green above, veined and pale or bluish beneath. A single flower stands in the fork of the stem, upon a hairy pendulous peduncle. The flower is often concealed by the loose soil or decayed vegetable matter; so that the leaves with their petioles are the only parts that appear above the surface of the ground. There is no corolla. The calyx is very woolly, and divided into three broad concave acuminate segments, with the ends reflexed, of a deep brownish-purple colour on the inside, and of a dull purple inclining to greenish externally. The filaments, which are twelve in number, and of unequal length, stand upon the germ, and rise with a slender point above the anthers attached to them. Near the divisions of the calyx are three filamentous bodies, which may be considered as nectaries. The pistil consists of a somewhat hexagonal germ, and a conical grooved style, surmounted by six revolute stigmas. The capsule is six-celled, coriaceous, and crowned with the adhering calyx.

Canada snakeroot, or wild ginger, is an indigenous plant, inhabiting woods and shady places from Canada to Carolina. Its flowering period is

from April to July. All parts of the plant have a grateful aromatic odour, which is most powerful in the root. This is the officinal portion.

As we have seen it in the shops, it is in long, more or less contorted pieces, of a thickness from that of a straw to that of a goose-quill, brownish and wrinkled externally, whitish within, hard and brittle, and frequently furnished with short fibres. Its taste is agreeably aromatic and slightly bitter, said to be intermediate between that of ginger and serpentaria, but in our opinion bearing a closer resemblance to that of cardamom. The taste of the petioles, which usually accompany the root, is more bitter and less aromatic.

Among its constituents, according to Dr. Bigelow, are a light coloured, pungent, and fragrant essential oil, a reddish bitter resinous matter, starch, and gum; in addition to which Mr. Rushton found fatty matter, chlorophylle, and salts of potassa, lime, and iron. Mr. Procter found the resin to be acrid as well as bitter, and without aromatic properties. The root imparts its virtues to alcohol, and less perfectly to water.

Medical Properties and Uses. Wild ginger is an aromatic stimulant tonic, with diaphoretic properties, applicable to similar cases with serpentaria, which it resembles in its effects. It is said to be sometimes used by the country people as a substitute for ginger. From the close botanical analogy of the plant with the European *Asarum*, it might be supposed, like that, to possess emetic and cathartic properties: but such does not appear to be the case, at least with the dried root. It would form an elegant adjuvant to tonic infusions and decoctions. It may be given in powder or tincture. The dose in substance is twenty or thirty grains. W.

ASCLEPIAS INCARNATA. U.S. Secondary.

Flesh-coloured Asclepias.

“The root of *Asclepias incarnata*.” U. S.

ASCLEPIAS. See ASCLEPIAS TUBEROSA.

Asclepias incarnata. Willd. *Sp. Plant.* i. 1267. This species has an erect downy stem, branched above, two or three feet high, and furnished with opposite, nearly sessile, lanceolate, somewhat downy leaves. The flowers are red, sweet-scented, and disposed in numerous crowded erect umbels, which are generally in pairs. The nectary is entire, with its horn exerted. In one variety the flowers are white.

The plant grows in all parts of the United States, preferring a wet soil, and flowering from June to August. Upon being wounded it emits a milky juice. The root is the officinal portion. Its properties are probably similar to those of the *A. Syriaca*; but they have not, so far as we know, been fully tested. Dr. Griffith states that it has been employed by several physicians, who speak of it as a useful emetic and cathartic. (*Journ. of the Phil. Col. of Pharm.* iv. 283.) W.

ASCLEPIAS SYRIACA. U.S. Secondary.

Common Silk-weed.

“The root of *Asclepias Syriaca*.” U. S.

ASCLEPIAS. See ASCLEPIAS TUBEROSA.

A. Syriaca. Willd. *Sp. Plant.* i. 1265. The silk-weed has simple stems, from three to five feet high, with opposite, lanceolate-oblong, petiolate

leaves, downy on their under surface. The flowers are large, of a pale purple colour, sweet-scented, and arranged in nodding umbels, which are two or three in number. The nectary is bidentate. The pod or follicle is covered with sharp prickles, and contains a large quantity of silky seed-down, which has been sometimes used as a substitute for fur in the manufacture of hats, and for feathers in beds and pillows.

This species of *Asclepias* is very common in the United States, growing in sandy fields, on the road sides, and on the banks of streams from New England to Virginia. It flowers in July and August. Like the preceding species, it gives out a white juice when wounded, and has hence received the name of *milk-weed*, by which it is frequently called.

Dr. Richardson of Massachusetts found the root possessed of anodyne properties. He gave it with advantage to an asthmatic patient, and in a case of typhus fever attended with catarrh. In both instances it appeared to promote expectoration, and to relieve pain, cough, and dyspnœa. He gave a drachm of the powdered bark of the root, in divided doses, during the day; and employed it also in strong infusion. W.

ASCLEPIAS TUBEROSA. U.S. Secondary.

Butterfly-weed.

"The root of *Asclepias tuberosa*." U. S.

ASCLEPIAS. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Asclepiadaceæ.

Gen. Ch. Calyx small, five-parted. Corolla rotate, five-parted, mostly reflexed. Staminal crown (or nectary) simple, five-leaved; leaflets opposite the anthers, with a subulate averted process at the base. Stigmas with the five angles (corpuscles) opening by longitudinal chinks. Pollinia five distinct pairs. Torrey.

Asclepias tuberosa. Willd. *Sp. Plant.* i. 1273; Bigelow, *Am. Med. Bot.* ii. 59; Barton, *Med. Bot.* i. 239. The root of the *butterfly-weed* or *pleurisy-root* is perennial, and gives origin to numerous stems, which are erect, ascending or procumbent, round, hairy, of a green or reddish colour, branching at the top, and about three feet in height. The leaves are scattered, oblong-lanceolate, very hairy, of a deep rich green colour on their upper surface, paler beneath, and supported usually on short footstalks. They differ, however, somewhat in shape according to the variety of the plant. In the variety with decumbent stems, they are almost linear, and in another variety cordate. The flowers are of a beautiful reddish-orange colour, and disposed in terminal or lateral corymbose umbels. The fruit is an erect lanceolate follicle, with flat ovate seeds connected to a longitudinal receptacle by long silky hairs.

This plant differs from other species of *Asclepias* in not emitting a milky juice when wounded. It is indigenous, growing throughout the United States from Massachusetts to Georgia, and when in full bloom in the months of June and July, exhibiting a splendid appearance. It is most abundant in the Southern States. The root is the only part used in medicine.

This is large, irregularly tuberous, branching, often somewhat fusiform, fleshy, externally brown, internally white and striated, and in the recent state of a sub-acrid nauseous taste. When dried it is easily pulverized, and has a bitter but not otherwise unpleasant taste. It yields its virtues readily to boiling water.

Medical Properties and Uses. The root of the *Asclepias tuberosa* is diaphoretic and expectorant, without being stimulant. In large doses it is

often also cathartic. In the Southern States it has long been employed by regular practitioners in catarrh, pneumonia, pleurisy, consumption, and other pectoral affections; and appears to be decidedly useful if applied in the early stages, or, after sufficient depletion, when the complaint is already formed. Its popular name of *pleurisy-root* expresses the estimation in which it is held as a remedy in this disease. It has also been used advantageously in acute rheumatism, and might probably prove beneficial in our autumnal remittents. Dr. Eberle found it highly useful in dysentery. (*Eberle's Practice*, i. 216.) Much testimony might be advanced in proof of its possessing very considerable diaphoretic powers. It is said also to be gently tonic, and has been popularly employed in pains of the stomach arising from flatulence and indigestion.

From twenty grains to a drachm of the root in powder may be given several times a day; but as a diaphoretic it is best administered in decoction or infusion, made in the proportion of an ounce to the quart of water, and given in the dose of a teacupful every two or three hours till it operates.

W.

ASSAFÆTIDA. *U.S., Lond., Ed., Dub.*

Assafetida.

"The concrete juice of the root of *Ferula Assafætida*." *U.S.* "*Ferula Assafætida. Gummi-resina.*" *Lond., Dub.* "Gummy-resinous exudation of *Ferula Assafætida*, and probably *Ferula persica*." *Ed.*

FERULA. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Apiaceæ or Umbelliferae.

Gen. Ch. Fruit oval, compressed plane, with three streaks on each side. *Willd.*

Ferula Assafætida. Willd. *Sp. Plant.* i. 1413; Kœmpfer, *Amœnitat. Exotic.* 535. t. 536. The following description of the plant which yields assafetida is derived from that by Kœmpfer, who wrote from actual observation. The root is perennial, fleshy, tapering, when of full size as large as a man's leg, beset with many strong fibres near the top, externally blackish, internally white, and abounding in an excessively fetid, opaque, milky juice. The leaves, all of which spring immediately from the root, are six or seven in number, nearly two feet long, bipinnate, with the leaflets alternate, smooth, variously sinuated and lobed, sometimes lanceolate, of a deep green colour and fetid smell. From the midst of the leaves rises a luxuriant, herbaceous stem, from six to nine feet in height, two inches in diameter at the base, simple, erect, round, smooth, striated, and terminating in large plano-convex umbels with numerous radii. The flowers are pale yellow; the seeds oval, flat, foliaceous, and of a reddish-brown colour. The plant is said to differ greatly both in the shape of its leaves, and the character of its fetid product, according to the situation and soil in which it grows.

It is a native of Persia and perhaps other countries of the East; and flourishes most abundantly in the mountainous provinces of Laar and Chorrassan, where its juice is collected. Burns, in his travels into Bokhara, states that the plant is eaten with relish by the people, and that sheep crop it greedily. Some suppose that other species of *Ferula* contribute to the production of the assafetida of commerce; and the *F. persica* is admitted among its probable sources by the Edinburgh College. This plant grows also in Persia, and has a strong odour of the drug.

The oldest plants are most productive, and those under four years old are not considered worth cutting. At the season when the leaves begin to fade, the earth is removed from about the top of the root, and the leaves and stem being twisted off near their base, are thrown with other vegetable matters over the root, in order to protect it from the sun. After some time the summit of the root is cut off transversely, and the juice which exudes having been scraped off, another thin slice is removed, in order to present a fresh surface for exudation. This process is repeated at intervals till the root ceases to afford juice, and perishes. During the whole period of collection, which occupies nearly six weeks, the solar heat is as much as possible excluded. The juice collected from numerous plants is put together, and allowed to harden in the sun.

Assafetida is brought to this country either from India, whither it is conveyed from Bushire, or by the route of Great Britain. It sometimes comes in mats, but more frequently in cases, the former containing eighty or ninety, the latter from two hundred to four hundred pounds. It is sometimes also imported in casks.

As found in the shops it is in irregular masses, of a softish consistence when not long exposed, of a yellowish or reddish-brown colour externally, exhibiting when broken an irregular whitish, somewhat shining surface, which soon becomes red on exposure to the air, and ultimately passes into a dull yellowish-brown. This change of colour is characteristic of assafetida; and is ascribed to the influence of air and light upon its resinous ingredient. The masses appear as if composed of distinct portions intermingled and agglutinated together, sometimes of white, almost pearly tears, embedded in a darker, softer, and more fetid paste. Occasionally the *tears* are found in a separate state, though very rarely in the commerce of this country. They are roundish, oval, or irregular, and generally flattened, from the size of a pea to that of a large almond, yellowish or brownish externally and white within, and not unlike ammoniac tears, for which they might be mistaken except for their odour, which, however, is weaker than that of the masses. (*Pereira*.) The odour of assafetida is alliaceous, extremely fetid, and tenacious; the taste, bitter, acrid, and durable. The effect of time and exposure is to render it more hard and brittle, and to diminish the intensity of its smell and taste, particularly the former. Kœmpfer assures us that one drachm of the fresh juice diffuses a more powerful odour through a close room than one hundred pounds of the drug as usually kept in the stores. Assafetida softens by heat without melting, and is of difficult pulverization. Its sp. gr. is 1.327. (*Berzelius*.) It is inflammable, burning with a clear, lively flame. It yields all its virtues to alcohol, and forms a clear tincture, which becomes milky on the addition of water. Macerated in water it produces a turbid red solution, and triturated with that fluid gives a white or pink-coloured milky emulsion of considerable permanence. In one hundred parts, Pelletier found 65 parts of resin, 19.44 of gum, 11.66 of bassorin, 3.60 of volatile oil, with traces of supermalate of lime. Brandes, the German chemist, obtained 4.6 parts of volatile oil, 47.25 of a bitter resin soluble in ether, 1.6 of a tasteless resin insoluble in ether, 1.0 of extractive, 19.4 of gum containing traces of potassa and lime united with sulphuric, phosphoric, acetic, and malic acids, 6.4 of bassorin, 6.2 of sulphate of lime, 3.5 of carbonate of lime, 0.4 of oxide of iron and alumina, 0.4 of malate of lime with resin, 6.0 of water, and 4.6 of impurities consisting chiefly of sand and woody fibre. The odour of the gum-resin depends on the *volatile oil*, which may be obtained separate by distillation with water or alcohol. It is lighter than water, colourless when first distilled, but becoming yellow with

age, of an exceedingly offensive odour, and of a taste at first flat, but afterwards bitter and acrid. It is said to contain a small portion of sulphur. The volatile oil and the bitter resin are the active principles.

Impurities and Adulterations. Assafœtida is probably not often purposely adulterated, but it frequently comes of inferior quality, and mixed with various impurities, such as sand and stones. Portions which are very soft, dark brown or blackish, with few or no tears, and indisposed to assume a red colour when freshly broken, should be rejected. We have been informed that a case seldom comes without more or less of this inferior assafœtida, and of many it forms the larger proportion. It is sold chiefly for horses.

Medical Properties and Uses. The effects of assafœtida on the system are those of a moderate stimulant, powerful antispasmodic, efficient expectorant, and feeble laxative. Its volatile oil is undoubtedly absorbed; as its peculiar odour may be detected in the breath and the secretions. As an antispasmodic simply, it is employed in the treatment of hysteria, hypochondriasis, convulsions of various kinds, spasm of the stomach and bowels unconnected with inflammation, and in those numerous irregular nervous disorders which accompany derangement of the different organs, or result from mere debility of the nervous system. From the union of expectorant with antispasmodic powers, it is highly useful in spasmodic pectoral affections, such as hooping-cough, asthma, and certain infantile coughs and catarrhs, complicated with disorder of the nervous apparatus, or with a disposition of the system to sink. In these last cases it was employed with great success by the late Dr. Jos. Parrish of Philadelphia.* In catarrhus senilis; the secondary stages of peripneumonia notha, croup, measles, and catarrh; in pulmonary consumption; in fact, in all cases of disease of the chest in which the lungs do not perform their office from want of due nervous energy, and in which inflammation is absent or has been sufficiently subdued, assafœtida may occasionally be prescribed with advantage. In the form of enema it may be beneficially employed in typhoid diseases attended with inordinate accumulation of air in the bowels, and in other cases of tympanitic abdomen. The same form will be found most convenient in the hysteric paroxysm, and other kinds of convulsion. In most cases its laxative tendency adds to its advantages; but in some instances must be counteracted by the addition of laudanum. It may often be usefully combined with purgative medicines in constipation of the bowels with flatulence.

It appears to have been known in the East from very early ages, and notwithstanding its repulsive odour, is at present much used in India and Persia as a condiment. Persons soon habituate themselves to its smell, which they even learn to associate pleasantly with the agreeable effects experienced from its internal use. Children with hooping-cough sometimes become fond of it; and older persons may be found, without going so far as India, who employ it habitually.

The medium dose is ten grains, which may be given in pill or emulsion. (See *Mistura Assafœtidæ*.) The tincture is officinal, and is frequently used. When given by injection it should be prepared by trituration with warm water. From half a drachm to two drachms may be administered at once in this way. As assafœtida is not apt to affect the brain injuriously, it may be given very freely when not contra-indicated by the existence of inflammatory action.

CITRUS. Sex. Syst. Polyadelphia Icosandria.—*Nat. Ord.* Aurantiaceæ.

Gen. Ch. *Calyx* five-cleft. *Petals* five, oblong. *Anthers* twenty, the filaments united into different parcels. *Berry* nine-celled. *Willd.*

This very interesting genus is composed of small evergreen trees, with ovate, or oval-lanceolate, and shining leaves, odoriferous flowers, and fruits which usually combine beauty of colour with a fragrant odour and grateful taste. They are all natives of warm climates, and where the winters are severe require the aid of artificial heat. Though the species are not numerous, great diversity exists in the character of the fruit; and many varieties, founded upon this circumstance, are noticed by writers. In the splendid work on the natural history of the *Citrus* by Risso and Poiteau, 169 varieties are described under the eight following heads:—1. sweet oranges, 2. bitter and sour oranges, 3. bergamots, 4. limes, 5. shaddocks, 6. limes, 7. lemons, and 8. citrons. Of these it is difficult to decide which have just claims to the rank of distinct species, and which must be considered merely as varieties. Those employed in medicine may be arranged in two sets, of which the orange, *C. Aurantium*, and the lemon, *C. Medica*, are respectively the types, the former characterized by a winged, the latter by a naked or nearly naked petiole. The form and character of the fruit which are not entirely constant, serve as the basis of the subdivisions. The *C. Decumana*, which yields the shaddock, agrees with the *C. Aurantium* in the form of its petiole; but its fruit is not officinal.

Citrus Aurantium. *Willd. Sp. Plant.* iii. 1427; *Woodv. Med. Bot.* p. 523. t. 188. The orange tree grows to the height of about fifteen feet. Its stem is round, very much branched, sometimes even from the base, and covered with a smooth, shining, greenish-brown bark. In the wild state, and before inoculation, it is often furnished with axillary spines. The leaves are ovate, pointed, entire, smooth, and of a shining pale green colour. When held between the eye and the light, they exhibit numerous small transparent vesicles, filled with essential oil; and when rubbed between the fingers, are highly fragrant. Their footstalks are about an inch long, and are furnished with wings or lateral appendages. The flowers, which have a delightful odour, are large, white, and attached by short peduncles, singly

or in clusters, to the smaller branches. The calyx is saucer-shaped, with pointed teeth. The petals are oblong, concave, white, and beset with numerous small glands. The filaments are united at their base in three or more distinct portions, and support yellow anthers. The germen is roundish, and bears a cylindrical style, which is terminated by a globular stigma. The fruit is a spherical berry, often somewhat flattened at its base and apex, rough, of a yellow or orange colour, and divided internally into nine vertical cells, in each of which are from two to four seeds, surrounded by a pulpy matter. The rind of the fruit is double, consisting of a thin exterior layer which abounds in vesicles filled with a fragrant essential oil, and of an interior one which is thick, white, fungous, insipid, and inodorous. There are two varieties of the *C. Aurantium*, considered by some as distinct species. They differ chiefly in the character of the fruit, which in one is sweet, in the other sour and bitterish. The first retains the original botanical title, the second is called *Citrus vulgaris* by Risso and others. The Seville orange is the product of the latter.

This beautiful evergreen, in which the fruit is mingled, in every stage of its growth, with the blossoms and foliage, is one of those productions of the tropics which have been applied to the most numerous purposes both of utility and ornament. A native of China and India, it was introduced into Europe at a very early period, was transplanted to America soon after the first settlement of this continent, and is now found in every civilized country where the climate is favourable to its cultivation. In colder countries, it is one of the most cherished ornaments of the hot-house, though in this situation its beauties are not fully developed, and its fruit does not attain perfection. It flourishes in the most southern portion of our own country, particularly in the neighbourhood of St. Augustine in Florida, whence we annually derive a considerable supply of very fine oranges. The tree also grows in the gardens about New Orleans, but is sometimes destroyed by the frosty winters which are incident to that climate. The fruit is brought to us chiefly from the South of Europe and the West Indies. The Havana oranges have the sweetest and most pleasant flavour.

Various parts of the orange-tree are used in medicine. The leaves, which are bitter and aromatic, are employed in some places in the state of infusion as a gently stimulant diaphoretic. The fresh flowers impart to water distilled from them their peculiar fragrance; and the preparation thus obtained is much esteemed in the South of Europe for its antispasmodic virtues. The distilled water of orange-flowers is recognised as officinal by all the British Colleges. An oil is also obtained from the flowers by distillation, which is called *neroli* in France, and is much used in perfumery, and in the composition of *liqueurs*. It is an ingredient of the famous Cologne water. That obtained from the flowers of the Seville or bitter orange (*C. vulgaris*), is deemed the sweetest. It was introduced into the London and Edinburgh Pharmacopœias, with the title of *Aurantii Oleum*, to serve for the preparation of orange-flower water. The fruit is applied to several purposes. Small unripe oranges, about the size of a cherry or less, previously dried, and rendered smooth by a turning lathe, are sometimes employed to maintain the discharge from issues. They are preferred to peas on account of their agreeable odour, and by some are thought to swell less with the moisture; but this is denied by others, and it is asserted that they require to be renewed at the end of twenty-four hours. These fruits are sometimes kept in the shops under the name of *orange berries*. They are of a grayish or greenish-brown colour, a fragrant odour, and bitter taste, and are said to be used for flavouring cordials. An essential oil is obtained from them by

distillation, known to the French by the name of *essence de petit grain*, and employed for similar purposes with that of the flowers. The oil, however, which now goes by this name, is said to be distilled chiefly from the leaves, and those of the bitter orange yield the best. The unripe fruit is also among the Dublin officiala. The London College recognises the ripe fruit, the Dublin the juice of the fruit. The juice of the Seville orange is sour and bitterish, and forms with water a refreshing and grateful drink in febrile diseases. It is employed for the same purposes with the juice of the lemon, which it resembles in containing citric acid, though in much smaller proportion. The sweet orange is much more pleasant to the taste, and is very extensively used as a light refrigerant article of diet in inflammatory diseases, care being taken to reject the membranous portion, and to swallow only the pulp. The rind of the mature fruit is the only part directed by the U. S. Pharmacopœia. The outer portion is that considered official, as the inner is wholly destitute of useful properties, and by its affinity for moisture produces a disposition in the peel to become mouldy. The best mode of separating the outer rind, when its desiccation and preservation are desired, is to pare it from the orange in narrow strips with a sharp knife, exactly as we pare an apple. When the object is to apply the fresh rind to certain pharmaceutic purposes, as, for instance, to the preparation of the *confection of orange peel*, it is best separated by a grater. The dried peel, sold in our drug stores, is usually that of the Seville orange, and is chiefly brought from the Mediterranean.

Properties. Orange peel has a grateful aromatic odour, and a warm bitter taste, which depend upon the essential oil contained in its vesicles. The rind of the Seville orange is much more bitter than that of the other variety. Both yield their sensible properties to water and alcohol. The essential oil may be obtained by simple expression from the fresh grated rind, or by distillation with water. It has properties closely resembling those of the oil of lemons, and may be used for similar purposes.

Medical Properties and Uses. Orange peel is a mild tonic, carminative, and stomachic, but is seldom used alone. It is chiefly employed to communicate a pleasant flavour to other medicines, to correct their nauseating properties, and to assist their stimulant impression upon the stomach. It is a frequent and very useful addition to bitter infusions and decoctions, as those of gentian, quassia, columbo, and especially Peruvian bark. It is obviously improper to subject orange peel to long boiling; as the essential oil on which its virtues chiefly depend is thus driven off. The dose in substance is from half a drachm to a drachm three times a day. Large quantities are sometimes productive of mischief, especially in children, in whom violent colic and even convulsions are sometimes induced by it. We have known the case of a child, in which death resulted from eating the rind of an orange.

When the object in the use of orange peel is simply to obtain its agreeable flavour, the rind of the sweet orange is preferable; as a tonic, that of the Seville orange.

| AVENÆ FARINA. U.S.

Oatmeal.

“Meal prepared from the seeds of *Avena sativa*.” U.S.

Off. Syn. AVENA. *Avena sativa*. *Semina integumentis nudata*. Lond.; AVENA. Seeds of *Avena sativa*. Ed.; AVENA SATIVA. Farina ex seminibus. Dub.

Farine d'avoine, Fr.; Hafermehl, Germ.; Farina dell'avena, Ital.; Harina de avena, Span.

AVENA. *Sex. Syst.* Triandria Digynia.—*Nat. Ord.* Graminaceæ.

Gen. Ch. Calyx two-valved, many flowered, with a twisted awn on the back. Willd.

Avena sativa. Willd. *Sp. Plant.* i. 446. The common oat is so well known that a minute description would be superfluous. It is specifically distinguished by its “loose panicle, its two-seeded glumes, and its smooth seeds, one of which is awned.” It was known to the ancients, and is now cultivated in all civilized countries; but its original locality has not been satisfactorily ascertained. It grows wild in Sicily, and is said to have been seen by Anson in the Island of Juan Fernandez, on the coast of Chili.

This grain, though cultivated chiefly for horses, is very nourishing, and is largely consumed as food by the inhabitants of Scotland, the North of Ireland, Brittany, and some other countries. The seeds deprived of their husk are called *groats*, and are directed by the British Colleges; but are not officinal on this side of the Atlantic. It is only the meal, prepared by grinding the seeds, that is kept in our shops.

Oatmeal contains, according to Vogel, in 100 parts, 59 of starch, 4·30 of a grayish substance resembling rather coagulated albumen than gluten, 8·25 of sugar and a bitter principle, 2·50 of gum, 2 of fixed oil, and 23·95 of fibrous matter including loss. It has no smell, is very slightly but not unpleasantly bitter, and yields most of its nutritive matter with facility to boiling water.

Gruel made with oatmeal affords a nutritious, bland, and easily digested aliment, admirably adapted to inflammatory diseases; and from its somewhat laxative tendency, preferable in certain cases to the purely mucilaginous or amylaceous preparations. It is very often administered after brisk cathartics, in order to render them easier and at the same time more efficient in their action. It is sometimes also used in the form of enema, and the meal, boiled with water into a thick paste, forms an excellent emollient cataplasm. *Oatmeal gruel* may be prepared by boiling an ounce of the meal with three pints of water to a quart, straining the decoction, allowing it to stand till it cools, and then pouring off the clear liquor from the sediment. Sugar and lemon-juice may be added to improve its flavour; and raisins are not unfrequently boiled with the meal and water for the same purpose.

AZEDARACH. U.S. Secondary.

Azedarach.

“The bark of the root of *Melia Azedarach*.” U.S.

MELIA. *Sex. Syst.* Decandria Monogynia. *Nat. Ord.* Meliaceæ.

Gen. Ch. Calyx five-toothed. Petals five. Nectary cylindrical, toothed, bearing the anthers in the throat. Drupe with a five-celled nut. Willd.

Melia Azedarach. Willd. *Sp. Plant.* ii. 558; Michaux, *N. Am. Sylv.* iii. 4. This is a beautiful tree, rising thirty or forty feet in height, with a trunk fifteen or twenty inches in diameter. When standing alone, it attains less elevation, and spreads itself out into a capacious summit. Its leaves are large, and doubly pinnate, consisting of smooth, acuminate, denticulate, dark green leaflets, which are disposed in pairs with an odd one at the end. The flowers, which are of a lilac colour and delightfully fragrant, are disposed in beautiful axillary clusters near the extremities of the branches. The fruit is a round drupe, which, when ripe, is about as large as a cherry, and of a yellowish colour.

This species of *Melia* is variously called *pride of India*, *pride of China*, and *common bead tree*. It is a native of Syria, Persia, and the North of India, and is cultivated for ornamental purposes in various parts of the eastern and western continents. It is abundant in our Southern States, where it lines the streets of cities, and adorns the environs of dwellings, and in some places has become naturalized. North of Virginia it does not flourish, though small trees may sometimes be seen in sheltered situations. Its flowers appear early in the spring. The fruit is sweetish to the taste, and, though said by some to be poisonous, is eaten by children at the South without inconvenience, and is even reputed to be powerfully vermifuge. But the bark of the root is the part chiefly employed. It is preferred in the recent state, and is therefore scarcely to be found in the shops at the North. It has a bitter, nauseous taste, and yields its virtues to boiling water.

Medical Properties and Uses. This bark is cathartic and emetic, and in large doses is said to produce narcotic effects similar to those of *Spigelia*, especially if gathered at the season when the sap is mounting. It is considered in the Southern States an efficient anthelmintic, and appears to enjoy, in some places, an equal degree of confidence with the pink-root. It is thought also to be useful in those infantile remittents which resemble verminose fevers, without being dependent on the presence of worms. The form of decoction is usually preferred. A quart of water is boiled with four ounces of the fresh bark to a pint, of which the dose for a child is a table-spoonful every two or three hours, till it affects the stomach or bowels. Another plan is to give a dose morning and evening for several successive days, and then to administer an active cathartic. W.

BARIUM.

Barium.

This is the metallic radical of the earth baryta, and is the basis of several officinal compounds. It was first obtained in 1808, by Sir H. Davy, who describes it as a difficultly fusible metal, of a dark gray colour, effervescing violently with water, and considerably heavier than sulphuric acid. When exposed to the air, it instantly becomes covered with a crust of baryta, and, when gently heated, burns with a deep red light. The only officinal preparations of barium are the chloride, and the carbonate and sulphate of the protoxide of barium (baryta). The carbonate and sulphate are found as mineral substances, and are not used as medicines, but as the materials from which the chloride may be prepared.

Baryta may be obtained from the native carbonate by intense ignition with carbonaceous matter; or from the native sulphate by ignition with charcoal, which converts it into sulphuret of barium, subsequent solution of the sulphuret in nitric acid, and strong ignition of the nitrate formed to

dissipate the acid. As thus obtained it is an anhydrous solid, caustic, alkaline, difficultly fusible, and of a grayish-white colour. Its sp. gr. is about 4. It acts on the animal economy as a poison. When sprinkled with water it slakes like lime, becomes hot, and is reduced to the state of a white pulverulent hydrate, containing one eq. of water. The same hydrate is formed in mass, when the anhydrous earth is made into a paste with water, and exposed to a red heat in a platinum crucible. The excess of water is expelled, and the hydrate, undergoing fusion, may be poured out and allowed to congeal. Baryta dissolves in water, and forms the test called *barytic water*. A boiling saturated solution, as it cools, yields crystals of baryta, containing much water of crystallization.

Baryta consists of one eq. of barium 68.7, and one eq. of oxygen 8=76.7. Its symbol is BaO. B.

BARYTÆ CARBONAS. U.S., Lond., Ed.

Carbonate of Baryta.

Carbonate de baryte, *Fr.*; Kohlensaurer Baryt, *Germ.*; Barite carbonata, *Ital.*; Carbonato de barito, *Span.*

The officinal carbonate of baryta is the native carbonate, a mineral discovered in 1783, by Dr. Withering, in honour of whom it is called *Witherite*. It is rather a rare mineral. It is found in Sweden and Scotland, but most abundantly in the lead-mines of the North of England. It occurs usually in grayish, or pale yellowish-gray, fibrous masses, but sometimes crystallized. Its sp. gr. varies from 4.2 to 4.4. Generally it is strongly translucent, but sometimes opaque. It effervesces with acids, and, before the blowpipe, melts into a white enamel without losing its carbonic acid. It is distinguished from the carbonate of strontia, with which it is most liable to be confounded, by its greater specific gravity, and by the absence of a reddish flame upon burning alcohol impregnated with its nitric solution. On the animal economy, it acts as a poison.

When pure, carbonate of baryta is entirely soluble in muriatic acid. If any sulphate of baryta be present, it will be left undissolved. If neither ammonia nor sulphuretted hydrogen produce discoloration or a precipitate in the muriatic solution, the absence of alumina, iron, copper, and lead is shown. Lime may be detected by adding to the muriatic solution an excess of sulphuric acid, which will throw down the baryta as a sulphate, but retain the lime in solution, discoverable by a precipitate being produced by carbonate of soda.

Carbonate of baryta consists of one eq. of carbonic acid 22.12, and one of baryta 76.7=98.82. Its only officinal use is to make the chloride of barium. (See *Barii Chloridum*.)

Off. Prep. Barii Chloridum, U. S., Lond., Ed. B.

BARYTÆ SULPHAS. Ed., Dub.

Sulphate of Baryta.

Heavy spar, Baroselenite; Sulfate de baryte, *Fr.*; Schwefelsaurer Baryt, *Germ.*; Barite solfata, *Ital.*

The native sulphate of baryta is used in Pharmacy with the same view as the native carbonate; namely, to obtain the chloride of barium. The U. S. and London Pharmacopœias direct for this purpose the carbonate of baryta,

and the Dublin College the sulphate; while the Edinburgh College retains both, giving a separate formula for the use of each, according to the option of the operator. (See *Barii Chloridum*.)

Sulphate of baryta is a heavy lamellar, brittle mineral, varying in sp. gr. from 4.4 to 4.6. It is generally translucent, but sometimes transparent or opaque, and its usual colour is white or flesh-red. When crystallized, it is usually in the form of a very flat rhombic prism. Before the blowpipe, it strongly decrepitates, and melts into a white enamel, which, in the course of ten or twelve hours, falls to powder. By this treatment, it is partially converted into sulphuret of barium, and, if applied to the tongue, will give a taste like that of putrid eggs, which arises from the formation of sulphuretted hydrogen. This salt, on account of its great insolubility, is not poisonous. When ground to fine powder, it is sometimes mixed with white lead; but it impairs the quality of that pigment. It consists of one equivalent of acid 40.1, and one of baryta $76.7 = 116.8$.

BELLADONNA. U.S., Lond., Ed.

Belladonna.

“The leaves of *Atropa Belladonna*.” *U. S.*, *Ed.* “*Atropa Belladonna. Folia.*” *Lond.*

Off. Syn. ATROPA BELLADONNA. *Folia et radix. Dub.*

Belladone, Fr.; *Gemeine Tollkirsche, Wolfskirsche, Germ.*; *Belladonna, Ital.*; *Belladonna, Belladama, Span.*

ATROPA. Sex. Syst. Pentandria Monogynia.—*Nat. Ord.* Solanaceæ.

Gen. Ch. Corolla bell-shaped. *Stamens* distant. *Berry* globular, two-celled. *Willd.*

Atropa Belladonna. Willd. *Sp. Plant.* i. 1017; Woodv. *Med. Bot.* p. 230. i. 82. The belladonna or *deadly nightshade* is an herbaceous perennial plant, with a fleshy creeping root, from which rise several erect, round, purplish, branching stems, to the height of about three feet. The leaves, which are attached by short footstalks to the stem, are in pairs of unequal size, oval, pointed, entire, of a dusky green colour on their upper surface, and paler beneath. The flowers are large, bell-shaped, pendent, of a dull reddish colour, and supported upon solitary peduncles, which rise from the axils of the leaves. The fruit is a roundish berry with a longitudinal furrow on each side, at first green, afterwards red, ultimately of a deep purple colour, bearing considerable resemblance to a cherry, and containing, in two distinct cells, numerous seeds, and a sweetish violet-coloured juice. The calyx adheres to the base of the fruit.

The plant is a native of Europe, where it grows in shady places, along walls, and amidst rubbish, flowering in June and July, and ripening its fruit in September. The leaves are the only part directed by the United States, London, and Edinburgh Pharmacopœias; the root also is ordered by the Dublin College. The former should be collected in June or July, the latter in the autumn or early in the spring, and from plants three years old or more.

Properties. The *dried leaves* are of a dull greenish colour, with a very faint narcotic odour, and a sweetish, subacid, slightly nauseous taste. The *root* is long, round, from one to several inches in thickness, branched and fibrous, externally when dried of a reddish-brown colour, internally whitish, of little odour, and a feeble sweetish taste. Both the leaves and root, as

well as all other parts of the plant, impart their active properties to water and alcohol. By the researches of the German chemist Brandes, it was rendered probable that these properties resided in a peculiar alkaline principle, which he supposed to exist in the plant combined with an excess of malic acid, and appropriately named *atropia*. Besides the malate of atropia, Brandes found in the dried herb two azotized principles, a green resin (*chlorophylle*), wax, gum, starch, albumen, lignin, and various saline ingredients. The alkaline principle was afterwards detected by M. Runge; and the fact of its existence was established beyond question by the experiments of Geiger and Hesse, who obtained it from an extract prepared with the stems and leaves of the plant. It was first, however, procured in a state of purity by Mein, a German apothecary, who extracted it from the root.* *Atropia* crystallizes in white, silky prisms; is inodorous and of a bitter taste; dissolves easily in absolute alcohol and ether, but very slightly in water, and more freely in all these liquids hot than cold; melts at a temperature above 212° , and is volatilized unchanged; restores the colour of litmus paper reddened by the acids; forms soluble salts with the sulphuric, nitric, muriatic, and acetic acids; and, in a very dilute solution, produces, when applied to the eye, a speedy and durable dilatation of the pupil. Like the other vegetable alkalies, it consists of carbon, hydrogen, oxygen, and nitrogen—its formula being $C_{34} H_{23} NO_6$. Lübekind has described, under the name of *belladonnin*, a volatile alkaline principle, wholly distinct from atropia, which he obtained from belladonna; but it yet remains to be seen whether this was not the product of the process. (See *Am. Journ. of Pharm.* xiii. 127.)

Medical Properties and Uses. The action of belladonna is that of a powerful narcotic, possessing also diaphoretic and diuretic properties, and somewhat disposed to operate upon the bowels. Orfila infers from his experiments, and from known facts, that it has little intensity of local action, but is absorbed, and entering the circulation, exercises its influence upon the nervous system, especially upon the brain. Among the first obvious

* The following is the process employed by Mein. The roots of plants two or three years old were selected. Of these, reduced to an extremely fine powder, 24 parts were digested, for several days, with 60 parts of alcohol of 86 or 90 per cent. The liquid having been separated by strong expression, the residue was treated anew with an equal quantity of alcohol; and the tinctures, poured together and filtered, were mixed with one part of hydrate of lime, and frequently shaken for twenty-four hours. The copious precipitate which now formed was separated by filtering; and diluted sulphuric acid was added drop by drop to the filtered liquor, till slightly in excess. The sulphate of lime having been separated by a new filtration, the alcoholic liquid was distilled to one-half, then mixed with 6 or 8 parts of pure water, and evaporated with a gentle heat till the whole of the alcohol was driven off. The residual liquid was filtered, cautiously evaporated to one-third, and allowed to cool. A concentrated aqueous solution of carbonate of potassa was then gradually added, so long as the liquid continued to be rendered turbid; and the mixture was afterwards suffered to rest some hours. A yellowish resinous substance which opposes the crystallization of the atropia was thus precipitated. From this the liquid was carefully decanted, and a small additional quantity of the solution of the carbonate was dropped into it, till it no longer became turbid. A gelatinous mass now gradually formed, which, at the end of twelve or twenty-four hours, was agitated in order to separate the mother waters, then thrown upon a filter, and dried by folds of unsized paper. The substance thus obtained, which was atropia in an impure state, was dissolved in five times its weight of alcohol; and the solution, having been filtered, was mixed with six or eight times its bulk of water. The liquor soon became milky, or was rendered so by evaporating the excess of alcohol, and, in the course of twelve or twenty-four hours, deposited the atropia in the form of light yellow crystals, which were rendered entirely pure and colourless by washing with a few drops of water, drying on blotting paper, and again treating with alcohol as before. From twelve ounces of the root, Mein obtained by this process twenty grains of the pure alkali. (*Journ. de Pharm.* xx. 87.)

effects which it produces when taken in the usual dose, and continued for some time, are dryness and stricture of the fauces and neighbouring parts, with slight uneasiness or giddiness of the head, and more or less dimness of vision. The practitioner should watch for these effects as signs of the activity of the medicine, and should gradually increase the dose till some one of them is experienced in a slight degree, unless the object at which he aims should be previously attained; but so soon as they occur the dose should be diminished, or the use of the narcotic suspended for a time. When taken in too large a quantity, belladonna is capable of producing the most deleterious effects. It is in fact a powerful poison, and many instances are recorded in which it has been accidentally swallowed or purposely administered with fatal consequences. All parts of the plant are poisonous. It is not uncommon, in countries where the belladonna grows wild, for children to pick and eat the berries, allured by their fine colour and sweet taste. Soon after the poison has been swallowed, its peculiar influence is experienced in dryness of the mouth and fauces, great thirst, difficult deglutition, nausea and ineffectual retching, vertigo, intoxication or delirium, attended with violent gestures, and sometimes with fits of laughter, and followed by a comatose state. The pupil is dilated and insensible to light, the face red and tumid, the mouth and jaws spasmodically affected, the stomach and bowels insusceptible of impressions, in fact the whole nervous system prostrate and paralyzed. A feeble pulse, cold extremities, subsultus tendinum, deep coma or delirium, and sometimes convulsions, precede the fatal termination. Dissection discloses appearances of inflammation in the stomach and intestines; and it is said that the body soon begins to putrefy, swells, and becomes covered with livid spots, while dark blood flows from the mouth, nose, and ears. To obviate the poisonous effects of belladonna, the most effectual method is to evacuate the stomach as speedily as possible, either by means of emetics, or the stomach-pump, and afterwards to cleanse the bowels by purgatives and enemata. It is not probable that vinegar, which has been recommended, can be of any essential service as an antidote. The infusion of galls might possibly be useful, and, if the experiments of M. Runge can be relied on, lime-water or the alkaline solutions would render the poisonous matter which remained in the stomach inert.

Notwithstanding the tremendous energy of this narcotic when taken in very large doses, it has been used as a medicine, even from very early times. The leaves were first employed externally to discuss scirrhus tumours, and heal cancerous and other ill-conditioned ulcers; and were afterwards administered internally for the same purpose. Much evidence of their beneficial influence in these affections is on record, and even Dr. Cullen has spoken in their favour; but this application of the remedy has fallen into disuse. It is at present more esteemed in nervous diseases. The German practitioners are much in the habit of using it in whooping-cough, in the advanced stages of which it is undoubtedly sometimes beneficial. In neuralgia it is one of the most effectual remedies in our possession; and we ourselves can bear testimony to its usefulness in this complaint. Hufeland recommends it in the convulsions dependent on scrofulous irritation. It has been prescribed also in chorea, epilepsy, hydrophobia, mania, paralysis, amaurosis, rheumatism, gout, obstinate intermittents, dropsy, and jaundice; and in such of these affections as have their seat chiefly in the nervous system, it may sometimes do good. It is said to have been effectually employed in several cases of strangulated hernia. In Germany it has within a few years acquired great credit as a preventive of scarlatina—an application of the remedy first suggested by the famous author of the *homœopathic doc-*

trine,* and founded upon the idea, that, as the symptoms produced by scarlatina in the nervous system closely resemble those which result from large doses of belladonna, the former might be prevented, or at least moderated, by establishing the latter, as small-pox is prevented by vaccination, or rendered milder if the system has already come partially under its influence.

Applied to the eye, belladonna has the property of dilating the pupil exceedingly, and for this purpose is sometimes employed by European oculists previously to the operation for cataract. In cases of partial opacity of the crystalline lens, confined to the centre of that body, vision is temporarily improved by a similar use of the remedy; and it may also perhaps be beneficially used, when, from inflammation of the iris, there is danger of a permanent closure of the pupil. For these purposes, a strong infusion of the plant, or a solution of the extract, may be dropped into the eye, or a little of the extract itself rubbed upon the eyelids. The same application of the remedy has been recommended in cases of morbid sensibility of the eye. The decoction or extract of belladonna applied to the neck of the uterus, is asserted to have hastened tedious labour dependent on rigidity of the os tinæ; and spasmodic stricture of the urethra, neck of the bladder, and sphincter ani, and painful uterine affections have been relieved by the local use of the extract, either smeared upon bougies, or administered by injection. In the latter mode it has sometimes relieved strangulated hernia. The inhalation of the vapour from a decoction of the leaves or extract has been highly recommended in spasmodic asthma. For this purpose, two drachms of the leaves, or fifteen grains of the aqueous extract are employed to the pint of water. Relief is said to have been obtained in phthisis by smoking the leaves, infused when fresh in a strong solution of opium, and then dried.

Belladonna may be given in substance, infusion, or extract. The dose of the powdered leaves is for children from the eighth to the fourth of a grain, for adults one or two grains, repeated daily, or twice a day, and gradually increased till the peculiar effects of the medicine are experienced. An infusion may be prepared by adding a scruple of the dried leaves to ten fluidounces of boiling water, of which from one to two fluidounces is the dose for an adult. The extract is more used in the United States than any other preparation. (See *Extractum Belladonnæ*.)

Benjoin, Fr.; Benzoe, Germ.; Belzoino, Ital.; Benjui, Span.

The botanical source of benzoin was long uncertain. At one time it was generally supposed in Europe to be derived from the *Laurus Benzoin* of this country. This error was corrected by Linnæus, who, however, committed another, in ascribing the drug to the *Croton Benzoë*, a shrub which he afterwards described under the name of *Terminalia Benzoin*. Mr. Dry-

* Hahnemann of Leipsick.

ander was the first who ascertained the true benzoin tree to be a *Styrax*; and his description, published in the 77th vol. of the English Philosoph. Transact., has been copied by most subsequent writers. The specimen by which Mr. Dryander decided the generic character, was obtained by Sir Jos. Banks from Mr. Marsden at Sumatra.

STYRAX. Sex. Syst. Decandria Monogynia.—*Nat. Ord. Styracæ.*

Gen. Ch. Calyx inferior. Corolla funnel-shaped. Drupe two-seeded. Willd. .

Styrax Benzoin. Willd. Sp. Plant. ii. 623; Woodv. Med. Bot. p. 294. t. 102. This is a tall tree of quick growth, sending off many strong round branches, covered with a whitish downy bark. Its leaves are alternate, entire, oblong, pointed, smooth above, and downy beneath. The flowers are in compound, axillary clusters, nearly as long as the leaves, and usually hang all on the same side upon short slender pedicels.

The benzoin, or benjamin tree as it is sometimes called, is a native of Sumatra, Java, Borneo, Laos, and Siam. (*Ainslie.*) By wounding the bark near the origin of the lower branches, a juice exudes, which hardens upon exposure, and constitutes the *benzoin* of commerce. A tree is thought of a proper age to be wounded at six years, when its trunk is about seven or eight inches in diameter. The operation is performed annually, and the product on each occasion from one tree never exceeds three pounds. The juice which first flows is the purest, and affords the whitest and most fragrant benzoin. It is exported chiefly from Acheen in Sumatra, and comes into the western markets in large masses packed in chests and casks, and presenting externally the impression of the reed mats in which they were originally contained.

Two kinds of benzoin are distinguishable in the market, one consisting chiefly of whitish tears united by a reddish brown connecting medium, the other of brown or blackish masses, without tears. The first is the most valuable, and has been called *benzoë amygdaloides*, from the resemblance of the white grains to fragments of blanched almonds; the second is sometimes called *benzoë in sortis*—benzoin in sorts—and usually contains numerous impurities. Between these two kinds there is every gradation. We have seen specimens of this balsam consisting exclusively of yellowish-white homogeneous fragments, which, when broken, presented a perfectly smooth, clear, white, shining surface. These were no doubt identical in constitution with the tears of the larger masses.

Properties. Benzoin has an agreeable and fragrant odour, with very little taste; but when chewed for some time, leaves a sense of irritation in the mouth and fauces. It breaks with a resinous fracture, and presents a mottled surface of white and brown or reddish-brown; the white spots being smooth and shining, while the remainder, though sometimes shining and even translucent, is usually more or less rough and porous, and often exhibits impurities. In the inferior kinds, the white spots are very few or entirely wanting. Benzoin is easily pulverized, and while in the process of being powdered is apt to excite sneezing. Its sp. gr. is from 1.063 to 1.092. When heated, it melts and emits thick, white, pungent fumes, which excite cough when inhaled, and consist chiefly of benzoic acid. It is wholly soluble, with the exception of impurities, in alcohol; and is precipitated by water from the solution, rendering the liquor milky like the gum-resins. It imparts to boiling-water a notable proportion of benzoic acid. Lime-water and the alkaline solutions partially dissolve it, forming benzoates, from which the acid may be precipitated by the addition of another, having stronger affinity for the base. Its chief constituents are resin and benzoic acid; and

it therefore belongs to the balsams. The white tears, and the brownish connecting medium, are said by Stolze to contain very nearly the same proportion of acid, which, according to Bucholz, is 12·5 per cent., to Stolze 19·8 per cent. The resin is of three different kinds, one extracted from the balsam along with the benzoic acid by a boiling solution of carbonate of potassa in excess, another dissolved by ether from the residue, and the third affected by neither of these solvents. Besides benzoic acid and resin, the balsam contains a minute proportion of extractive, and traces of volatile oil.

Medical Properties and Uses. Benzoin, like the other balsams, is stimulant and expectorant, and was formerly employed in various pectoral affections; but, except as an ingredient of the compound tincture of benzoin, it has fallen into almost entire disuse. Trousseau and Pidoux recommended it strongly, in the way of fumigation, in chronic laryngitis. Either the air of the chamber may be impregnated with its vapour by placing a small portion upon some live coals, or the patient may inhale the vapour of boiling water to which the balsam has been added. It is employed in pharmacy for the preparation of benzoic acid (see *Acidum Benzoicum*); and the milky liquor resulting from the addition of water to its alcoholic solution, is sometimes used as a cosmetic, under the impression that it renders the skin soft and tender. In the East Indies it is burnt by the Hindoos as a perfume in their temples.

BISMUTHUM. *U. S., Lond., Ed., Dub.*

Bismuth.

Tinglass; Etain de glace, Bismuth, *Fr.*; Wissmuth, *Germ.*; Bismutte, *Ital.*; Bismut, *Span.*

Bismuth is a peculiar metal, occurring usually in the metallic state, occasionally as a sulphuret, and rarely as an oxide. It is by no means generally diffused, being principally found in Saxony. It occurs also in Cornwall, and has been found at Monroe, Conn., seventeen miles west of New-Haven. It is obtained almost entirely from the native bismuth, which is heated by means of wood or charcoal, whereby the metal is fused and separated from its gangue. Almost all the bismuth of commerce comes from Saxony.

Bismuth was first distinguished as a metal by Agricola in 1520. Before that period it was confounded with lead. It is a brittle, pulverizable, brilliant metal, of a crystalline texture, and of a white colour with a slight reddish tint. Its crystals are in the form of cubes. It undergoes but a slight tarnish in the air. Its sp. gr. is 9·8, and its melting point 476°. At a high temperature, in close vessels, it volatilizes, and may be distilled over. When heated in the open air to a full red heat, it takes fire, and burns with a faint blue flame, forming an oxide of a yellow colour. This is the *protoxide*, and consists of one equivalent of bismuth 71, and one of oxygen 8 = 79. Besides this oxide, bismuth forms a *sesquioxide* of a brown colour, very like the deutoxide of lead, and consisting of two equiv. of metal 142, and three of oxygen 24 = 166. Bismuth is acted on feebly by muriatic acid, but violently by nitric acid, which dissolves it with a copious extrication of red fumes. Sulphuric acid when cold has no action on it, but at a boiling heat effects its solution with the extrication of sulphurous acid. As it occurs in commerce, it is generally contaminated with a little arsenic, the presence of which may be detected by its not being completely

soluble in an excess of nitric acid. It may be purified from all contaminating metals, by dissolving the bismuth of commerce in diluted nitric acid, precipitating the clear solution by adding it to water, and reducing the white powder thus obtained (subnitrate of bismuth) with black flux. The same precipitate is obtained by adding ammonia to the nitric solution; and if the supernatant liquor should be blue, the presence of copper is indicated. If the precipitate is yellowish, iron is present.

Pharmaceutical Uses, &c. Bismuth, in an uncombined state, is not used in medicine, but is employed pharmaceutically to obtain the subnitrate of bismuth, the only medicinal preparation formed from this metal. In the arts, it is used to form a white paint for the complexion, called *pearl white*; and as an ingredient of the best pewter. Its consumption is limited by the small quantity of the metal which is supplied to commerce, this being computed not to exceed annually eleven or twelve thousand pounds.

BROMINUM. *U.S. Secondary.*

Bromine.

Off. Syn. BROMINIUM. *Lond.*

Brome, *Fr.*; Brom, *Germ.*; Bromo, *Ital.*

Bromine is an elementary body, possessing many analogies with chlorine and iodine. It was discovered in 1826 by Balard, a chemist of Montpellier, in the bittern of sea-salt works, in which it exists as a bromide of magnesium. Since then it has been discovered in the waters of the ocean, in certain marine animals and vegetables, in numerous salt springs, both in Europe and America, and, in two instances, in the mineral kingdom—in an ore of zinc, and in the cadmium of Silesia. In the United States it was first discovered by Professor Silliman, who found it in the bittern of the salt works at Salina, in the state of New York, where it exists apparently in considerable quantities. It has been detected also in the waters of the Saratoga Springs, and was found by the late Professor Emmet, of the University of Virginia, in the Kenhawa water.

Preparation. Bromine is prepared by passing a current of chlorine through bittern, and then agitating it strongly with a portion of ether. The chlorine decomposes the bromide of magnesium present in the bittern, forming a chloride of magnesium; and the disengaged bromine dissolves in the ether, to which it communicates a hyacinth-red colour. The ethereal solution of bromine is next decanted, and treated with a concentrated solution of caustic potassa, whereby the bromine is converted into bromide of potassium, and bromate of potassa. In the mean time the ether loses its colour and becomes pure, and may be again employed in dissolving fresh portions of bromine. Having in this way obtained a sufficient quantity of the salts above mentioned, their solution is evaporated to dryness, and the dry mass calcined at a red heat, in order to convert the bromate of potassa into bromide of potassium. The bromide is next decomposed by distilling it, with sulphuric acid and deutoxide of manganese, from a retort furnished with a bent tube plunging into water contained in a bottle. The acid combines with potassium and oxygen, so as to form sulphate of potassa, and the liberated bromine distils over, and condenses under the water.

Properties. Bromine is a volatile liquid, of a dark red colour when viewed in mass, but hyacinth-red in thin layers. Its taste is very caustic, and its smell strong and disagreeable, having some resemblance to that of chlorine.

Its density is very nearly 3. At 4° below zero it becomes a hard, brittle, crystalline solid, having a dark leaden colour, and a lustre nearly metallic. It boils at about 117°, forming a reddish vapour resembling that of nitrous acid, and of the sp. gr. 5·39. It evaporates readily, a single drop being sufficient to fill a large flask with its peculiar vapour. This vapour extinguishes flame, but previously communicates to it a greenish colour at its base, and a red one above.

Bromine is sparingly soluble in water to which it communicates an orange colour, more soluble in alcohol, and still more so in ether. The alcoholic and ethereal solutions lose their colour in a few days, and become acid from the generation of hydrobromic acid. It bleaches vegetable substances like chlorine, and decomposes organic matters, such as wood, cork, resins, volatile oils, &c. Its combination with starch has a yellow colour. It corrodes the skin and gives it a deep yellow stain.

Bromine is intermediate in its affinities between chlorine and iodine; since its combinations are decomposed by chlorine, while, in its turn, it decomposes those of iodine. Its equiv. number is 78·4 and its symbol Br. It forms acids with both oxygen and hydrogen, called bromic and hydrobromic acids, which are analogous both in properties and composition to the corresponding compounds of chlorine and iodine. In testing for bromine in mineral or saline waters, the water is evaporated in order to crystallize most of the salts. The solution, after having been filtered, is placed in a narrow tube, and a few drops of strong liquid chlorine are added. If this addition produces an orange colour, bromine is present. The water, in order that the test may succeed, must be free from organic matter, and the chlorine not added in excess.

Medical Properties. Bromine, from its analogy to iodine, was early tried as a remedy, and the result has demonstrated its value as a therapeutic agent in certain forms of disease. It acts, like iodine, by stimulating the lymphatic system and promoting absorption, but is generally supposed to possess more energy. It has been employed in bronchocele and other tumours, scrofula, amenorrhœa, chronic diseases of the skin, and hypertrophy of the ventricles. Magendie recommends its employment in cases in which iodine does not operate with sufficient activity, or has lost its effect by habit. The form in which it is employed is aqueous solution, the dose of which, containing one part of bromine to forty of distilled water, is about six drops taken several times a day. Of its compounds, the bromides of potassium, iron, and mercury have been chiefly tried in medicine. The former has been introduced as a new officinal in the last London Pharmacopœia. (See *Potassii Bromidum*.) The *bromide of iron* and the *two bromides of mercury* will be noticed in the Appendix.

Bromine, when given in an overdose, acts as an irritant poison.

CALAMUS. U.S. Secondary.

Sweet Flag.

“The rhizoma of *Acorus Calamus*.” U. S.

Off. Syn. ACORUS. *Acorus Calamus.* *Rhizoma.* Lond.; CALAMUS AROMATICUS. *Rhizoma of Acorus Calamus, var. a, vulgaris.* Ed.

Acorus vrai, Acorus odorant, Fr.; Kalmuswurzel, Germ.; Calamo aromatico, Ital., Span.

ACORUS. Sex. Syst. Hexandria Monogynia.—Nat. Ord. Acoraceæ.

Gen. Ch. Spadix cylindrical, covered with florets. Corolla six-petalled, naked. Style none. Capsule three-celled. Willd.

Acorus Calamus. Willd. *Sp. Plant.* ii. 199; Barton, *Med. Bot.* ii. 63. The sweet flag, or calamus, has a perennial, horizontal, jointed, somewhat compressed root (rhizome), from half an inch to an inch thick, sometimes several feet in length, sending off numerous round and yellowish or whitish fibres from its base, and bunches of brown fibres resembling coarse hair from its joints, internally white and spongy, externally whitish with a tinge of green, variegated with triangular shades of light brown and rose colour. The leaves are all radical, sheathing at the base, long, sword-shaped, smooth, green above, but of a red colour variegated with green and white near their origin from the root. The scape or flower-stem resembles the leaves, but is longer, and from one side, near the middle of its length, sends out a cylindrical spadix, tapering at each end, about two inches in length, and crowded with greenish-yellow flowers. These are without calyx, and have six small, concave, membranous, truncated petals. The fruit is an oblong capsule, divided into three cells, and containing numerous oval seeds.

This is an indigenous plant, growing abundantly throughout the United States, in low, wet, swampy places, and along the sides of ditches and streams, and flowering in May and June. It is also a native of Europe and Western Asia; and a variety of the same species is found in India. The European plant differs from the American in some unimportant particulars. The leaves as well as root have an aromatic odour; but the latter only is used in medicine. It should be collected late in the autumn or in the spring. After removal from the ground, the roots are washed, freed from their numerous fibres, and dried with a moderate heat. By the process of drying they lose nearly one-half their diameter, but are improved in odour and taste.

Properties. The roots, as found in the shops, are in pieces of various lengths, somewhat flattened, externally wrinkled and of a yellowish-brown colour, and presenting on their under surface numerous minute circular spots, indicating the points at which the fibres were inserted. Their texture is light and spongy, their colour internally whitish or yellowish-white, and their fracture short and rough. Sometimes pieces are brought into the market consisting exclusively of the interior portion of the root. They are usually long, slender, irregularly quadrangular, and of a grayish-white colour; and are prepared by paring off the outer coat with a knife. The odour of calamus is strong and fragrant; its taste warm, bitterish, pungent, and aromatic. Its active principles are taken up by boiling water. From one hundred parts of the fresh root of the European plant, Trommsdorff obtained 0.1 part of volatile oil, 2.3 of a soft resin, 3.3 of extractive with a little chloride of potassium, 5.5 of gum with some phosphate of potassa, 1.6 of starch, analogous to inulin, 21.5 of lignin, and 65.7 of water. Sixteen ounces of the dried root afforded to Neumann about two scruples of volatile oil. The oil is at first yellow, but ultimately becomes red, and has the smell and taste of calamus. The extractive matter has an acrid and sweetish taste. The root is sometimes attacked by worms, and deteriorates by keeping.

The root of the Indian variety is said to be less thick than the European, and to have a stronger and more pleasant taste and smell. It is supposed by some to be the true calamus of the ancients, though the claims of either variety to this honour have not been certainly established.

Medical Properties and Uses. Calamus is a stimulant tonic, possessing the ordinary virtues of the aromatics. It may be taken with advantage in pain or uneasiness of the stomach or bowels arising from flatulence, and

forms a useful adjuvant to tonic or purgative medicines, in cases of torpor or debility of the alimentary canal. It was probably known to the ancients; but the *calamus aromaticus* of Dioscorides was a different product, having been derived, according to Dr. Royle, from a species of *Andropogon*. The medicine is at present much neglected, though well calculated to answer as a substitute for more costly aromatics. The dose in substance is from a scruple to a drachm. An infusion, made in the proportion of an ounce of the root to a pint of boiling water, is sometimes given in the dose of a wine-glassful or more.

CALCII CHLORIDUM. U.S., Lond.

Chloride of Calcium.

Off. Syn. CALCIS MURIAS. Ed., Dub.

Muriate of lime, Hydrochlorate of lime; Chlorure de calcium, Hydrochlorate de chaux, *Fr.*; Chlorkalcium, Salzsaurer Kalk, *Germ.*

Chloride of calcium is a compound of chlorine and calcium, the metallic radical of lime. It is placed in the list of the *Materia Medica* in the United States Pharmacopœia, but processes for preparing it are given by the London, Edinburgh and Dublin Colleges. It may be readily formed by saturating muriatic acid with chalk or marble, evaporating to dryness, and heating to redness. The muriatic acid, by reacting with the lime, forms chloride of calcium and water, the latter of which is dissipated at a red heat. The London College forms the chloride from chalk in the following manner. "Take five ounces of chalk, and ten fluidounces, each, of hydrochloric acid and distilled water. Having mixed the acid and water together, add the chalk gradually to the mixture to perfect saturation. After the effervescence shall have ceased, filter the liquor, and evaporate it to dryness. Put the dry salt in a crucible, and having fused it, pour it out upon a clean stone slab. When it has cooled, break it into pieces, which must be kept in bottles well stopped." The Edinburgh process is substantially the same with the London. The only differences are that the Edinburgh College uses white marble in fragments, and obtains the chloride in crystals, by evaporating the solution resulting from the saturation to one-half, and setting it aside in a cold place.

In making chloride of calcium, the Dublin College uses the residuum of their process for obtaining water of ammonia. The latter preparation being procured by the action of lime on muriate of ammonia, the residuum is a solution of chloride of calcium; but it generally contains adhering ammonia and an excess of lime. Any quantity of this residuum is taken, and, after being filtered, is evaporated to dryness. The excess of lime may be saturated with muriatic acid, or converted into an insoluble carbonate by exposing the solution for some time to the air.

Properties. Chloride of calcium, in the fused or anhydrous state, as it is directed or understood to be in the U. S., London and Dublin Pharmacopœias, is a colourless, slightly translucent, hard and friable solid, of an acrid, bitter, saline taste, extremely deliquescent, very soluble in water, and readily soluble in rectified spirit. On account of its avidity for water, the fused salt is used for drying gases, and for bringing alcohol to its highest degree of concentration. It is employed for the latter purpose by the London and Dublin Colleges. The crystallized salt, as directed by the Edinburgh College, is also very deliquescent, and has the form of colourless, transparent, striated, six-sided prisms. The crystals, on exposure to heat,

first dissolve in their water of crystallization, and, after this has evaporated, undergo the igneous fusion. With ice or snow they form a powerful freezing mixture. Solution of chloride of calcium, when pure, yields no precipitate with ammonia, chloride of barium, or ferrocyanuret of potassium dissolved in a large quantity of water. The non-action of these tests severally shows the absence of magnesia, sulphuric acid, and iron.

Chloride of calcium exists in solution in the water of the ocean and of many springs. It is usually associated with common salt and chloride of magnesium, from which it is separated with difficulty.

Composition. Chloride of calcium consists of one eq. of chlorine 35.42, and one of calcium 20.5=55.92. When crystallized, it contains six eqs. of water=54.

Chloride of calcium is used medicinally in solution only. In this state it is officinal under the name of *Liquor Calcii Chloridi*, under which title its medicinal properties will be given.

CALCIS HYDRAS. *Lond.*

Hydrate of Lime.

“Calx recèns usta aquà resoluta.” *Lond.*

Slaked lime; Hydrate de chaux, Chaux éteinte, *Fr.*; Gelöschter Kalk, *Germ.*

The London College has introduced hydrate of lime as a new officinal in their revised Pharmacopœia of 1836. It is readily prepared by adding water to quicklime by small quantities at a time, until the earth falls into powder. During the operation, which is called the *slaking of lime*, a great deal of heat is evolved, and the water forms with the earth a solid compound, called *hydrate of lime*. It is white, pulverulent, and much less caustic than lime. Exposed to the air it attracts carbonic acid, and when subjected to a high temperature, abandons the water which it contains, and returns to the state of lime. When perfectly formed, the hydrate contains nearly one-fourth of its weight of water, corresponding to one eq. of the earth and one of water. Its only officinal use is to form chlorinated lime, or bleaching powder. (See *Calx Chlorinata*.) The tests for hydrate of lime are the same as for lime. (See *Calx*.)

Lime.

“Lime recently prepared by calcination.” *U. S.* “Calx recèns usta.” *Lond.*

Quicklime; Chaux, Chaux vive, *Fr.*; Kalk, *Germ.*; Calce, *Ital.*; Calviva, *Span.*

Lime, which ranks among the alkaline earths, is a very important pharmaceutical agent, and forms the principal ingredient in several standard preparations. The London and Edinburgh Colleges give processes for its preparation; but in the United States and Dublin Pharmacopœias, it is placed exclusively in the list of the *Materia Medica*.

Lime is a very abundant natural production. It is never found pure, but mostly combined with acids, as with carbonic acid in chalk, marble, calcareous spar, limestone, and shells; with sulphuric acid in the different species of gypsum or plaster of Paris; with phosphoric acid in the bones of animals, and with silica in a great variety of minerals.

Preparation. Lime is prepared by calcining, with a strong heat, some form of the native carbonate. The carbonic acid is thus expelled, and the lime remains behind. When the lime is intended for nice chemical operations, it should be obtained from pure white marble, or from oyster shells. For the purposes of the arts, it is procured from common limestone, by calcining it in kilns of peculiar construction. When obtained in this way, it is generally impure, being of a grayish colour, and containing alumina, silica, sesquioxide of iron, and occasionally a little magnesia and oxide of manganese.

The officinal lime of the United States and Dublin Pharmacopœias is the lime of commerce, and, therefore, impure. That obtained by the processes of the London and Edinburgh Colleges is purer. The London College takes a pound of chalk, and exposes it, broken into small pieces, to a very strong fire for an hour. The Edinburgh directions are to heat white marble, broken into small fragments, in a covered crucible, at a full red heat for three hours, or till the residuum, when slaked and suspended in water, no longer effervesces with muriatic acid.

Properties. Lime is a grayish-white solid, having a strong, caustic, alkaline taste, and the sp. gr. 2·3. It is very refractory in the fire, having been fused only by the compound blowpipe of Dr. Hare. Exposed to the air, it absorbs moisture and carbonic acid, and falls into a white powder. In this state, it is a mixture of carbonate and hydrate. On account of its liability to change by being kept, lime, intended for pharmaceutical purposes, should be recently burnt. It acts upon vegetable colours as a strong alkaline base. Upon the addition of water, it cracks and falls into powder, with the evolution of heat. (See *Calcis Hydras*, Lond.) If it dissolve in muriatic acid without effervescence, the fact shows the absence of carbonic acid, and that the lime has been well burnt. If any silica be present, it will be left undissolved by the muriatic acid. If the solution give no precipitate with ammonia, the absence of iron and alumina is shown.

Lime is but sparingly soluble in water, requiring, at the temperature of 60°, about seven hundred times its weight of that liquid for complete solution. Contrary to the general law, it is less soluble in hot than in cold water. The solution formed is called lime-water.

Lime is the oxide of a peculiar metal, called calcium, and consists of one eq. of calcium 20·5, and one of oxygen 8=28·5. It is distinguished from the other alkaline earths by forming a very deliquescent salt with muriatic acid (*chloride of calcium*), and a sparingly soluble one with sulphuric acid. All acids, acidulous, ammoniacal, and metallic salts, borates, alkaline carbonates, and astringent vegetable infusions, are incompatible with it.

Medical Properties. Lime acts externally as an escharotic, and was formerly applied to ill-conditioned ulcers. Mixed with caustic potassa, it forms the *Potassa cum Calce*. As an internal remedy, it is always administered in solution. (See *Liquor Calcis*.)

Economical Uses. The uses of lime in the arts are numerous. It is employed in the fabrication of soap, to render the fixed alkalies caustic; as a manure for fertilizing fields; and mixed with sand and water, as the ordinary cement of buildings.

Lime is used to prepare Alcohol, *Ed.*, not *Lond.*; Liquor Ammonia, *U. S.*, *Lond.*, *Ed.*, *Dub.*; Liquor Potassæ, *U. S.*, *Lond.*, *Ed.*, *Dub.*; Quiniæ Sulphas, *U. S.*; Spiritus Ammonia, *U. S.*, *Ed.*; Strychnia, *U. S.*, *Ed.*; Sulphur Præcipitatum, *U. S.*

CALX CHLORINATA. U.S., Lond., Ed.

Chlorinated Lime.

"A compound resulting from the action of chlorine on hydrate of lime."
U. S.

Chloride of lime, Hypochlorite of lime, Oxymuriate of lime, Bleaching powder; *Chlorure de chaux, Fr.; Chlorkalk, Germ.; Cloruro de calce, Ital.*

This substance was originally prepared, and brought into notice as a bleaching agent, in 1798, by Mr. Tennant of Glasgow. Subsequently it was found to have valuable properties as a medicine and disinfectant, and, accordingly, it has been successively introduced into the London, Edinburgh, and United States Pharmacopœias. The London College only has given a process for its preparation, which is as follows: "Take of Hydrate of Lime a pound; Chlorine as much as may be sufficient. Pass the chlorine over the lime, spread in a proper vessel, until it is saturated. Chlorine is very readily evolved from Hydrochloric [muriatic] Acid added to Bin-oxide [deutoxide] of Manganese, with a gentle heat."

This process of the London College is unnecessary; as chlorinated lime is made in large quantities, and of excellent quality, by the manufacturing chemist, for the use of the bleacher, dyer, and paper-maker. The following is the process pursued on the large scale. A chamber is constructed eight or nine feet high, built of siliceous sandstone, the joints being secured by a cement of pitch, rosin, and dry gypsum. At one end it is furnished with an air-tight door, and on each side with a glass window, to enable the operator to inspect the process during its progress. The slaked or hydrated lime is sifted and placed on wooden trays, eight or ten feet long, two broad, and one inch deep. These are piled within the chamber to the height of five or six feet on cross-bars, which, by keeping them about an inch asunder, favour the circulation of the gas over the lime.

The chlorine is generated in a leaden vessel nearly spherical, the lower portion of which is surrounded with an iron case, leaving an interstice two inches wide, intended to receive steam for the purpose of producing the requisite heat. In the leaden vessel are five apertures. The first is in the centre of the top, and receives a tube which descends nearly to the bottom, and through which a vertical stirrer passes, intended to mix the materials, and furnished, at the lower end, with horizontal cross-bars of iron, or of wood sheathed with lead. The second is for the introduction of the common salt and manganese. The third admits a syphon-shaped funnel, through which the sulphuric acid is introduced; the fourth is connected with a pipe to lead off the gas; and the fifth, which is near the bottom, receives a discharge pipe, passing through the iron case, and intended for drawing off the residuum of the operation.

The pipe passing from the leaden vessel terminates under water contained in a leaden chest or cylinder, where the gas is washed from muriatic acid. From this intermediate vessel, the chlorine finally passes, by means of a pretty large leaden pipe, through the ceiling of the chamber containing the lime. The process of impregnation generally lasts four days, in order to form a good bleaching powder. If the process be hastened, heat will be generated, which will favour the production of chloride of calcium, attended with a proportional diminution of chloride of lime.

The proportions of the materials employed for generating chlorinated lime vary in different manufactories. Those generally adopted are 10 cwt.

of the salt, mixed with from 10 to 14 cwt. of deutoxide of manganese; to which are added, in successive portions, from 12 to 14 cwt. of strong sulphuric acid, diluted before being used until its sp. gr. is reduced to about 1.65, which will be accomplished by adding about one-third of its weight of water. In manufactories in which sulphuric acid is also made, the acid intended for this process is brought to the sp. gr. of 1.65 only, whereby the expense of further concentration is saved.

Properties. Chlorinated lime is a dry or slightly moist, grayish-white, pulverulent substance, possessing an acrid, hot, bitter, astringent taste, and a feeble odour resembling that of chlorine. It possesses powerful bleaching properties. When perfectly saturated with chlorine, it dissolves almost entirely in water; but as ordinarily prepared, a large portion is insoluble, consisting of hydrate of lime. When exposed to heat, it gives off oxygen and some chlorine, and is converted into chloride of calcium. It is incompatible with the mineral acids, with carbonic acid, and the alkaline carbonates. The acids evolve chlorine copiously, and the alkaline carbonates cause a precipitate of carbonate of lime. (See *Liquor Sodæ Chlorinatæ*.)

Composition. Although the bleaching powder has been studied by a number of able chemists, its composition is still involved in doubt. Dr. Ure believes that it consists of hydrate of lime and chlorine, united in variable proportions, not correspondent to equivalent quantities. According to Brande, Grouvelle, and Phillips, the compound obtained when chlorine ceases to be absorbed, consists of one eq. of chlorine and two of hydrate of lime, resolvable, by water, into one eq. of hydrated chloride of lime which dissolves, and one of hydrate of lime which is left. Dr. Thomson, however, asserts that the substance has been so much improved in quality of late years, that good samples consist of single equivalents of chlorine and lime, and are almost entirely soluble in water. It thus appears that all the best authorities agree in considering the bleaching powder to contain lime and water, or their elements, together with chlorine. From the statement of Dr. Thomson, it may be assumed as probable that the essential part of the compound is the portion soluble in water. Hence, its ultimate constituents, exclusive of the elements of water, are one eq. of chlorine, one of calcium, and one of oxygen; the excess of lime found by Phillips and others, being a portion of the earth imperfectly hydrated, and, therefore, in an unfit state to be acted on by the chlorine. Three views are taken of the manner in which these elements are united to form the bleaching powder. The first makes it a chloride of lime, the second hypochlorite of lime with chloride of calcium, and the third, oxychloride of calcium. By doubling the elements present, it is easily shown by symbols, that the several views taken do not change the ultimate composition of the compound; for $2\text{CaO} + 2\text{Cl} = \text{CaO}, \text{ClO} + \text{CaCl} = 2\text{CaOCl}$.

The simplest view of the nature of the bleaching powder is that which supposes it a compound of chlorine and lime. The view which makes it a hypochlorite is that of Balard and Berzelius, and is supported by the fact that the compound smells of hypochlorous acid. On the other hand, if it contains chloride of calcium, it ought to deliquesce, unless it can be shown that the metallic chloride is in such a state of combination as to prevent this result. The third view, that it is an oxychloride, which assimilates its nature to that of the deutoxide of calcium, is held by Millon. According to this chemist, the quantity of chlorine taken up by a metallic protoxide, is regulated by the nature of its peroxide. The peroxide of calcium is a deutoxide (CaO_2); and Millon contends that, in the bleaching powder, by the replacement of the second equivalent of oxygen in the deutoxide, we

have the compound CaOCl . Again, the peroxide of potassium is represented by KO_2 , and Millon states that the bleaching compound which potassa (KO) makes with chlorine, is KOCl_2 . If further observation should show that the number of equivalents of chlorine, necessary to convert a protoxide into a bleaching compound, is always equal to the number of equivalents of oxygen required to convert it into a peroxide, it will go far to prove the correctness of Millon's views.

On the supposition that the bleaching powder is a hypochlorite of lime, with chloride of calcium, the mode of its formation is thus explained. Two eqs. of chlorine, by uniting separately with the elements of one eq. of lime, form one eq. of chloride of calcium, and one of hypochlorous acid, which latter combines with an additional eq. of lime, to form hypochlorite of lime. Upon the whole, considering the uncertainty as to the real nature of the compound under consideration, the name of *chlorinated lime*, adopted by the Pharmacopœias, is a judicious one, as involving no decision of its exact composition.

Impurities and Tests. Chlorinated lime may contain a great excess of lime, from imperfect impregnation with the gas. This defect will be shown by the large proportion insoluble in water. If it contain much chloride of calcium, it will be quite moist, which is always a sign of inferior quality. If long and insecurely kept, it deteriorates from the gradual formation of chloride of calcium and carbonate of lime. Several methods have been proposed for determining its bleaching and disinfecting power, which depends solely on the quantity of chlorine it contains. Welter proposed to add a solution of the bleaching powder to a standard solution of sulphate of indigo, in order to ascertain its decolorizing power; but the objection to this test is that the indigo of commerce is very variable in its amount of colouring matter. Dr. Ure has proposed muriatic acid to disengage the chlorine over mercury; but this test is liable to the fallacy that it will disengage carbonic acid as well as chlorine; and it has been shown by some unpublished experiments of Mr. Procter of this city, that the amount of disengaged gaseous matter is not in proportion to the decolorizing power. Mr. Dalton has proposed as a test, to add a solution of the bleaching powder to one of the sulphate of protoxide of iron, until the odour of chlorine is perceived. Chlorine is not disengaged until the iron is sesquioxidized, and the stronger the bleaching powder, the sooner this will be accomplished. Dr. Thomson and Professor Graham consider this test the best yet proposed.

The Pharmacopœias have given no satisfactory test of the value of chlorinated lime. The character given in the London and United States Pharmacopœias of entire solubility in dilute muriatic acid, with the evolution of chlorine, applies equally to good and bad samples. Assuming the chlorinated lime to be dry, and, therefore, free from chloride of calcium, it would follow that the quantity of oxalate of lime, thrown down by oxalic acid from the part of the powder soluble in water, would be proportional to the lime present, and, therefore, to the chlorine combined with it. This test is given by the Edinburgh College, with directions for measuring the bulk, after rest, of the precipitated oxalate of lime; but the plan is not practically convenient.

Medical Properties and Uses. Chlorinated lime, externally applied, is a desiccant and disinfectant, and has been used with advantage in solution as an application to ill-conditioned ulcers, burns, chilblains, and cutaneous eruptions, especially itch; as a gargle in putrid sorethroat; and as a wash for the mouth to disinfect the breath, and for ulcerated gums. Internally, it is a stimulant and astringent. It has been employed by Dr. Reid in the epi-

demic typhoid fever of Ireland; by the same practitioner, in dysentery, both by the mouth and injection, with the effect of correcting the fetor, and improving the appearance of the stools; by Cima, both internally and externally in scrofula; and by Dr. Varlez of Brussels in ophthalmia. Dr. Pereira has used a weak solution very successfully in the purulent ophthalmia of infants. In the febrile cases Dr. Reid found it to render the tongue cleaner and moister, to check diarrhœa, and induce sleep. The dose internally is from three to six grains, dissolved in one or two fluidounces of water, filtered, and sweetened with syrup. As it occurs of variable quality, and must be used in solution more or less dilute according to the particular purpose to which it is to be applied, it is impossible to give any very precise directions for its strength as an external remedy. From one to four drachms of the powder added to a pint of water, and filtered, will constitute a solution within the limits of strength ordinarily required. For the cure of itch, M. Derheims has recommended a much stronger solution—three ounces of the chloride to a pint of water, the solution being filtered, and applied several times a day as a lotion, or constantly by wet cloths. When applied to ulcers, their surface may be covered with lint dipped in the solution. When used as an ointment, to be rubbed upon scrofulous enlargements of the lymphatic glands, it may be made of a drachm of the chloride to an ounce of lard. Chlorinated lime acts, without doubt, by the chlorine which it contains; but it is not so eligible for some purposes as the solution of chlorinated soda. (See *Liquor Sodæ Chlorinatæ*.)

In consequence of its powers as a disinfectant, chlorinated lime is a very important substance in its application to medical police. It possesses the property of preventing or arresting animal and vegetable putrefaction, and, perhaps, of destroying pestilential and infectious miasms. It is consequently applicable to a great variety of purposes, more or less connected with the health or comfort of communities. It may be used with advantage for preserving bodies from exhaling an unpleasant odour before interment in the summer season. In juridical exhumations its use is indispensable, as it effectually removes the disgusting and insupportable fetor of the corpse. The mode in which it is applied in these cases, is to envelope the body with a sheet completely wet with a solution, made by adding about a pound of the chloride to a bucketful of water. It is employed also for disinfecting dissecting rooms, privies, common sewers, docks, and other places which exhale offensive effluvia. In destroying contagion and infection, it also appears to be highly useful. Hence hospitals, alms-houses, jails, ships, &c., may be purified by its means. In short, all places which may be deemed infectious, from having been the receptacle of cases of virulent disease, may be more or less disinfected by its use, after they have undergone the ordinary processes of cleansing.

The way in which chlorinated lime acts, is exclusively by its chlorine, which, being loosely combined, is disengaged by the slightest affinities. All acids, even the carbonic, disengage it; and as this acid is a product of animal and vegetable decomposition, noxious effluvia furnish the means, to a certain extent, of their own disinfection by this chloride. But the stronger acids disengage the chlorine far more readily, and among these, sulphuric acid is the cheapest and most convenient. Accordingly, the powder may be dissolved in a very dilute solution of sulphuric acid, or a small quantity of this acid may be added to an aqueous solution ready formed, in case a more copious evolution of chlorine is desired than that which takes place from the mere action of the carbonic acid of the atmosphere.

Chloride of lime may be advantageously applied to the purpose of puri-

ifying offensive water, a property which makes it invaluable on long voyages. When used for this purpose, from one to two ounces of the chloride may be mixed with about sixty-five gallons of the water. After the purification is effected, the water must be exposed for some time to the air and allowed to settle, before it is fit to drink. B.

CAMPHORA. U.S., Lond., Ed., Dub.

Camphor.

"A peculiar concrete substance derived from *Laurus Camphora*, and purified by sublimation." U.S. "*Laurus Camphora. Concretum sui generis, sublimatione purificatum.*" Lond. "Camphor of *Camphora officinarum.*" Ed. "*Laurus Camphora. Dryobalanops Camphora. Camphora.*" Dub.

Camphre, Fr.; Kampher, Germ.; Canfora, Ital; Alcanfor, Span.

The name of camphor has been applied to various concrete, white, odorous, volatile products, found in different aromatic plants, and resulting probably from some chemical change in their volatile oil. But commercial camphor is derived exclusively from two plants, the *Camphora officinarum* of Nees or *Laurus Camphora* of Linnæus, and the *Dryobalanops Camphora*; the former of which yields our officinal camphor, the latter, a product much valued in the East, but unknown in the commerce of this country and of Europe. The following observations apply to the officinal camphor.

CAMPHORA. Sex. Syst. Enneandria Monogynia.—Nat. Ord. Lauraceæ.

Gen. Ch. Flowers hermaphrodite, panicle, naked. Calyx six-cleft, papery, with a deciduous limb. Fertile stamens nine, in three rows; the inner with two stalked, compressed glands at the base; anthers four-celled; the outer turned inwards, the inner outwards. Three sterile stamens shaped like the first, placed in a whorl alternating with the stamens of the second row; three others stalked, with an ovate glandular head. Fruit placed on the obconical base of the calyx. Leaves triple-nerved, glandular in the axils of the principal veins. Leaf buds scaly. (Lindley, *Flora Medica*, 332.)

Among the species composing the genus *Laurus* of Linn., such striking differences have been observed in the structure of the flower and fruit, that botanists have been induced to arrange them in new genera. The camphor, cinnamon, and sassafras trees have been separated from the proper laurels by the German botanist Nees, and made the types of distinct genera, which have been adopted by Lindley and most other recent writers, and may be considered as well established. The United States Pharmacopœia virtually recognises the new arrangement by adopting the genus *Cinnamomum*, though it still attaches the two other plants to the *Laurus*.

Camphora officinarum. Nees, *Laurin*. 88.—*Laurus Camphora*. Willd. *Sp. Plant.* ii. 478; Woodv. *Med. Bot.* p. 681. t. 236.—*Persea Camphora*. Sprengel. The camphor tree is an evergreen of considerable size, having the aspect of the linden, with a trunk straight below, but divided above into many branches, which are covered with a smooth greenish bark. Its leaves, which stand alternately upon long footstalks, are ovate lanceolate, entire, smooth and shining, ribbed, of a bright yellowish-green colour on their upper surface, paler on the under, and two or three inches in length. The flowers are small, white, pedicelled, and collected in clusters, which are supported by long axillary peduncles. The fruit is a red berry resembling that of the cinnamon. The tree is a native of the most eastern parts of

Asia, and is found abundantly in China and Japan. It has been introduced into the botanical gardens of Europe, and is occasionally met with in the hotheuses of our own country.

The leaves have when bruised the odour of camphor, which is diffused through all parts of the plant, and is obtained from the root, trunk, and branches by sublimation. The process is not precisely the same in all places. The following is said to be the one pursued in Japan. The parts mentioned, particularly the roots and smaller branches, are cut into chips, which are placed, with a little water, in large iron vessels, surmounted by earthen capitals, furnished with a lining of rice-straw. A moderate heat is then applied, and the camphor, volatilized by the steam of the boiling water, rises into the capital, where it is condensed upon the straw. In China, the comminuted plant is said to be first boiled with water until the camphor adheres to the stick used in stirring, when the strained liquor is allowed to cool; and the camphor which concretes, being alternated with layers of earth, is submitted to sublimation.

Commercial History. Camphor, in the *crude* state, is brought to this country chiefly from Canton. It comes also from Batavia, Singapore, Calcutta, and very frequently from London. All of it is probably derived originally from the dominions of China and Japan. Two commercial varieties are found in the market. The cheapest and most abundant is the *Chinese camphor*, the greater part of which is produced in the island of Formosa, and thence taken to Canton. It comes in chests lined with lead, each chest containing about 130 pounds. It is in small grains or granular masses, which are of a dirty white colour, and frequently mixed with impurities. The other variety is variously called *Japan*, *Dutch*, or *tub* camphor, the first name being derived from the place of its origin, the second from the people through whom it is introduced into commerce, and the third from the recipient in which it is often contained. It comes usually from Batavia, to which port it is brought from Japan. Like the former variety, it is in grains or granular masses, but the grains are larger and of a pinkish colour, and there are fewer impurities, so that it yields a larger product when refined.

Crude camphor, as brought from the East, is never found in the shop of the apothecary. It must be refined before it can be used for medicinal purposes. The process for refining camphor was first practised in Europe by the Venetians, who probably derived it from the Chinese. It was afterwards transferred to the Dutch, who long enjoyed a monopoly of this business; and it is only within a few years, that the process has been generally known. It is now practised largely in this country, and the camphor refined in our domestic establishments is equal to any that was formerly imported. Crude camphor is mixed with a small proportion of quicklime,* and exposed, in a glass or earthenware vessel placed in a sand-bath, to a gradually increasing heat, by which it is melted, and ultimately converted into vapour, which condenses in a suitable recipient. Refined in this manner, it is usually in the form of large circular cakes, one or two inches thick, convex on one side, concave on the other, and perforated in the centre.

Properties. Camphor has a peculiar, strong, penetrating, fragrant odour; and a bitter, pungent taste, attended with a slight sense of coolness. It is beautifully white and pellucid, somewhat unctuous to the touch, friable, and yet possessed of a degree of tenacity which renders its reduction to a fine

* Six drachms of lime to two pounds and a half of camphor, French weight, or about 1 part to 50, is the proportion employed in the process of M. Clemandot, which enjoys some reputation in France. (*Journ. de Pharm.* ii. 321.)

powder very difficult, unless the cohesion of its particles be overcome by the addition of a minute proportion of alcohol, or other volatile liquid for which it has an affinity. It has a shining fracture, and a crystalline texture. Its sp. gr. varies from 0.9857 to 0.996. It therefore floats upon water, on the surface of which, if thrown in small fragments, it assumes very singular circulatory movements, which cease upon the addition of a drop of oil. Its volatility is so great, that even at ordinary temperatures it is wholly dissipated if left exposed to the air. When it is confined in bottles, the vapour condenses upon the inner surface, and, when allowed to stand for a long time in large bottles, partially filled, sometimes forms large and beautiful crystals. It melts at 288° F. and boils at 400°. (Turner.) In close vessels it may be sublimed unchanged. When allowed to concrete slowly from the state of vapour, it assumes the form of hexagonal plates. It is not altered by air and light. It readily takes fire, and burns with a brilliant flame, giving out much smoke, and leaving no residue. Water triturated with camphor dissolves a very minute proportion, not more, according to Berzelius, than the thousandth part of its weight; which, however, is sufficient to impart a decided odour and taste to the solvent. By the intervention of sugar or magnesia, particularly of the latter, a much larger proportion of the camphor is dissolved. (See *Aqua Camphoræ*.) Carbonic acid also increases the solvent power of water. Alcohol will take up seventy-five per cent. of its weight of camphor, which is precipitated upon the addition of water. Berzelius states, that 100 parts of alcohol of the sp. gr. 0.806, dissolve 120 parts at 50° F. It is soluble also without change in ether, the volatile and fixed oils, strong acetic acid, and the diluted mineral acids. By means of the spirit of nitric ether, it is rendered somewhat more soluble in water. By the action of strong sulphuric and nitric acids it is decomposed, the former carbonizing and converting it into artificial tannin; the latter, by the aid of repeated distillation, into a peculiar acid called the *camphoric*. The alkalies produce very little effect upon it. The resins unite with it, forming a soft tenacious mass, in which the odour of the camphor is sometimes almost extinguished and frequently diminished; and a similar softening effect results when it is triturated with the concrete oils.* Exposed to a strong heat in close vessels, camphor is decomposed, being resolved into a volatile oil and charcoal. It is closely analogous in character to the essential oils. Berzelius considers it a stearoptene entirely free from any mixture of eleoptene. (See *Olæa Volatilia*.) According to M. Dumas, it consists of a peculiar radical called *camphene* united with oxygen. Camphene, which is represented by pure oil of turpentine, is composed of eight equiv. of hydrogen 8, and ten equiv. of

* As this property of camphor may have a strong bearing injuriously or otherwise on pharmaceutical processes, it is desirable that the operator, as well as prescriber, should be aware of the degree of effect produced by different resinous substances which may be mixed with camphor. M. Planché has found that mixtures formed by triturating powdered camphor with powdered *dragon's blood*, *guaiac*, *assafetida*, or *galbanum*, assume and preserve indefinitely the pilular consistence; with *benzoin*, *tolu*, *ammoniack*, and *mastic*, though at first of a pilular consistence, afterwards become soft by exposure to the air; with *sagapenum* and *anime*, assume a permanently semi-liquid form; with *olibanum*, *opopanax*, *gamboge*, *euphorbium*, *bdellium*, *myrrh*, and *amber*, remain pulverulent though somewhat grumous; and with *tacamahac*, *resin of jalap*, *sandarac*, and *resinoid matter of cinchona*, preserve the form of powder indefinitely. The same experimenter observed, that camphor loses its odour entirely when mixed with *assafetida*, *galbanum*, *sagapenum*, *anime*, and *tolu*; retains a feeble odour with *dragon's blood*, *olibanum*, *mastic*, *benzoin*, *opopanax*, *tacamahac*, *guaiac*, and *ammoniack*; while, with the other resinous substances above mentioned, it either has its odour increased, or retains it without material change. (*Journ. de Pharm.* xxiv. 226.)

carbon $61.2 = 69.2$. With one equiv. of oxygen it forms camphor, with four equiv. of the same body hydrated camphoric acid, and with half an equiv. of hydrochloric acid, artificial camphor.*

Medical Properties and Uses. Camphor does not seem to have been known to the ancient Greeks and Romans. Europe probably derived it from the Arabians, by whom it was employed as a refrigerant. Much difference of opinion has prevailed as to its mode of action, some maintaining its immediate sedative influence, others considering it as a direct and decided stimulant. Its operation appears to be primarily and chiefly directed to the cerebral and nervous systems; and the circulation, though usually affected to a greater or less extent, is probably involved, for the most part, through the agency of the brain. It acts also, to a certain extent, as a direct irritant of the mucous membranes with which it is brought into contact, and may thus in some measure secondarily excite the pulse. The effects of the medicine vary with the quantity administered. In moderate doses it produces, in a healthy individual, mental exhilaration, increased heat of skin,

* *Sumatra Camphor. Borneo Camphor. Dryobalanops Camphor.* It has long been known that an excellent variety of camphor is produced in the islands of Sumatra and Borneo, by a forest tree which was thought by some to belong to the genus *Laurus*, by others was considered wholly distinct, but which, not having been seen by botanists, remained until a recent period undetermined. It was at length, however, described by Colebrooke, and is now recognised in systematic works as the *Dryobalanops Camphora*, or *D. aromatica*. It is a very large tree, sometimes attaining the height of one hundred feet, with a trunk six or seven feet in diameter, and ranking among the tallest and largest trees of the luxuriant regions where it grows. It is found both in Sumatra and Borneo, and is abundant on the N. W. coast of the former island. The camphor exists in concrete masses, which occupy longitudinal cavities or fissures in the heart of the tree, from a foot to a foot and a half long, at certain distances apart. The younger trees are generally less productive than the old. The only method of ascertaining whether a tree contains camphor is by incision. A party proceeds through the forest, wounding the trees till they find one which will answer their purpose, and hundreds may be examined before this object is attained. When discovered, the tree is felled and cut into logs, which are then split, and the camphor removed by means of sharp-pointed instruments. The masses are sometimes as thick as a man's arm; and the product of a middling sized tree is nearly eleven pounds; of a large one, double the quantity. The trees which have been wounded and left standing, often produce camphor seven or eight years afterwards. The *Dryobalanops* yields also a fragrant liquid, called in the East Indies *oil of camphor*, and highly valued as an external application in rheumatism and other painful affections. It is said to be found in trees too young to produce camphor, and is supposed to constitute the first stage in the developement of this substance; as it occupies the same cavities in the trunk, which are afterwards filled with the camphor. It holds, in fact, a large portion of this principle in solution, and may be made to yield an inferior variety by artificial concretion. The whole tree is pervaded more or less by the camphor or the oil; as the wood retains a fragrant smell, and, being on this account less liable to the attacks of insects, is highly esteemed for carpenter's work. The camphor-wood trunks occasionally brought to this country from the East Indies, are probably made out of the wood of the *Dryobalanops*.

It has been supposed that this variety of camphor is occasionally brought into the markets of Europe and America. But this is a mistake; as the whole produce of the islands is engrossed by the Chinese, by whom it is so highly valued, that it commands at Canton, according to Mr. Crawford, seventy-eight times, according to Mr. Reeves, one hundred times the price of ordinary camphor. A specimen, in our possession, which was sent to this country from Canton, as a curiosity, and kindly presented to us by Dr. Joseph Carson, is in tabular plates, of a foliaceous crystalline texture, white, somewhat translucent, of an odour analogous to that of common camphor, and yet decidedly distinct, and less agreeable. It has also a camphorous taste. It is more compact and brittle than ordinary camphor, but does not sink in water, and is easily pulverized without the addition of alcohol. It is, moreover, much less disposed to rise in vapour, and to condense on the inside of the bottle containing it. Like ordinary camphor, it is fusible, volatilizable, very slightly soluble in water, and freely soluble in alcohol and in ether. We have never met with it in the drug stores.

and occasional diaphoresis. The pulse is usually increased in fulness, but little, if at all, in force or frequency. According to the experiments of certain Italian physicians, it appears to have a tendency to the urinary and genital organs, producing a burning sensation along the urethra, and exciting voluptuous dreams.* Cullen, however, states that he has employed it fifty times, even in large doses, without having ever observed any effect upon the urinary passages. By many it is believed to allay irritations of the urinary and genital apparatus, and to possess antaphrodisiac properties. In its primary operation it allays nervous irritation, quiets restlessness, and produces a general placidity of feeling, which renders it highly useful in certain forms of disease attended with derangement of the nervous functions. In larger doses it displays a more decided action on the brain, producing more or less giddiness and mental confusion, with a disposition to sleep; and, in morbid states of the system, relieving pain and allaying spasmodic action. In immoderate doses it occasions nausea, vomiting, anxiety, faintness, vertigo, delirium, insensibility, coma, and convulsions, which may end in death. The pulse, under these circumstances, is at first reduced in frequency and force;† but as the action advances, it sometimes happens that symptoms of strong sanguineous determination to the head become evident, in the flushed countenance, inflamed and fiery eyes, and highly excited pulse.‡ There can be no doubt that it is absorbed; as its odour is observed in the breath and perspiration, though, as is asserted, not in the urine.

By its moderately stimulating powers, its diaphoretic tendency, and its influence over the nervous system, it is admirably adapted to the treatment of all diseases of a typhoid character, which combine with the enfeebled condition of the system, a frequent irritated pulse, a dry skin, and much nervous derangement, indicated by restlessness, watchfulness, tremors, subsultus, and low muttering delirium. Nor are its beneficial effects confined to typhoid diseases. With a view to its anodyne and narcotic influence, it is often used in those of an inflammatory character, as in our ordinary remittents, and the phlegmasiæ, particularly rheumatism, when the increased vascular action is complicated with derangement of the nervous system. In such cases, however, it should never be used until after proper depletion, and even then should be combined with such medicines as may obviate the slight stimulation it produces, and give it a more decided tendency to the skin; as, for instance, tartarized antimony, ipecacuanha, or nitre. In a great number of spasmodic and nervous disorders, and complaints of irritation, camphor has been very extensively employed. The cases of this nature to which experience has proved it to be best adapted, are dysmenorrhœa, puerperal convulsions and other nervous affections of the puerperal state, and certain forms of mania, particularly nymphomania, and that arising from the abuse of spirituous liquors. In some of these cases advantage may be derived from combining it with opium. Camphor has also been employed internally to allay that irritation of the urinary organs which is apt to be produced by cantharides.

It is much used externally as a local anodyne, generally dissolved in alcohol, oil, or acetic acid, and frequently combined with laudanum. In rheumatic and gouty affections, and various internal spasmodic and inflammatory complaints, it often yields relief when applied in this way. The ardor urinæ of gonorrhœa may be alleviated by injecting an oleaginous solution of camphor into the urethra; and the tenesmus from ascarides and

* N. Am. Med. and Surg. Journ. vol. ix. p. 442.

† Alexander, Experimental Essays, p. 227.—Orfila.

‡ Quarin, quoted by Woodville, Med. Bot., 2d ed., vol. iv. p. 687.

dysentery, by administering the same solution in the form of enema. A scruple or half a drachm of camphor in substance, added to a poultice, and applied to the perineum, allays the chordee, which is a painful attendant upon gonorrhœa.

The vapour of camphor has been inhaled into the lungs with benefit in cases of spasmodic cough; and a lump of it held to the nose is said to relieve that unpleasant fulness of the nostrils and coryza which attend a commencing catarrh.

Camphor may be given in substance in the form of bolus or pill, or diffused in water by trituration with various substances. The form of pill is objectionable; as in this state the camphor is with difficulty dissolved in the gastric liquors, and floating on the top, is apt to excite nausea, or pain and uneasiness at the upper orifice of the stomach. Orfila states, that when given in the solid form it is capable of producing ulceration in the gastric mucous membrane. The emulsion is almost always preferred. This is made by rubbing up the camphor with loaf sugar, gum Arabic, and water; and the suspension will be rendered more complete and permanent by the addition of a little myrrh. Milk is sometimes used as a vehicle, but is objectionable, as it is apt to become sour very speedily. The aqueous solution is often employed where only a slight impression is desired. For this purpose, the *Aqua Camphoræ* of the United States Pharmacopœia is preferable to the solution effected by simply pouring boiling water upon a lump of camphor, which is sometimes prescribed under the name of *camphor tea*.

The medium dose of camphor is from five to ten grains; but to meet various indications it may be diminished to a single grain or extended to a scruple. The injurious effects of an overdose are said to be best counteracted, after clearing out the stomach, by the use of opium.

CANELLA. *U. S., Lond., Ed.*

Canella.

“The bark of *Canella alba*.” *U. S., Ed.* “*Canella alba. Cortex.*” *Lond.*

Off. Syn. CANELLA ALBA. Cortex. *Dub.*

Canelle blanche, *Fr.*; Weisser Zimmt, *Canell, Germ.*; Cannella bianca, *Ital.*; Canela blanca, *Span.*

CANELLA. *Sex. Syst.* Dodecandria Monogynia.—*Nat. Ord.* Meliaceæ. *De Cand.* Canelleæ. *Lindley.*

Gen. Ch. Calyx three-lobed. Petals five. Anthers sixteen, adhering to an urceolate nectary. Berry one-celled with two or four seeds. *Willd.*

Canella was first made a distinct genus by the celebrated Professor Murray. It had previously been confounded, under the name of *Winterania*, with that to which the tree that produces the Winter's bark belongs. The latter is now recognised as a distinct genus with the title of *Drymis* or *Wintera*.

Canella alba. Willd. *Sp. Plant.* ii. 851; Woodv. *Med. Bot.* p. 694. t. 237. This is the only species of the genus. It is an erect tree, rising sometimes to the height of fifty feet, branching only at the top, and covered with a whitish bark, by which it is easily distinguished from other trees in the woods where it grows. The leaves are alternate, petiolate, oblong, obtuse, entire, of a dark green colour, thick and shining like those of the laurel, and of a similar odour. The flowers are small, of a violet colour, and grow in clusters upon divided footstalks, at the extremities of the branches. The fruit is an oblong berry, containing one, two, or three black and shining seeds.

The *Canella alba* is a native of Jamaica and other West India islands. The bark of the branches, which is the part employed in medicine, having been removed by an iron instrument, is deprived of its epidermis, and dried in the shade. It comes to us in pieces partially or completely quilled, occasionally somewhat twisted, of various sizes, from a few inches to two feet in length, from half a line to two or even three lines in thickness, and in the quill from half an inch to an inch and a half in diameter.

Properties. Canella has a pale orange-yellow colour, usually much lighter on the inner surface, an aromatic odour somewhat resembling that of cloves, and a warm, bitterish, very pungent taste. It is brittle, breaking with a short fracture, and yielding when pulverized a yellowish-white powder. Boiling water extracts nearly one-fourth of its weight; but the infusion, though bitter, has comparatively little of the warmth and pungency of the bark. It yields all its virtues to alcohol, forming a bright yellow tincture, which is rendered milky by the addition of water. By distillation with water it affords a large proportion of a yellow or reddish, fragrant, and very acrid essential oil. It contains, moreover, according to the analysis of MM. Petroz and Robinet, a saccharine substance resembling mannite, a peculiar very bitter extractive, resin, gum, starch, albumen, and various saline substances in small proportion. Canella has been sometimes confounded with Winter's bark, from which, however, it differs both in sensible properties and composition. It contains, for instance, no tannin or oxide of iron, both of which are ingredients in the latter. (See *Winters*.)

Medical Properties and Uses. Canella is possessed of the ordinary properties of the aromatics, acting as a local stimulant and gentle tonic, and producing upon the stomach a warming cordial effect, which renders it useful as an addition to tonic or purgative medicines in debilitated states of the digestive organs. It is scarcely ever prescribed except in combination. In the West Indies it is employed by the negroes as a condiment, and has some reputation as an antiscorbutic.

CANNA. *Ed.*

Canna Starch.

“Fecula of the root of an imperfectly determined species of *Canna*.” *Ed.*

Under the French name of *tous les mois*, a variety of fecula has recently been introduced into the markets of Europe and this country. It is said to be prepared, in the West India island of St. Kitts, by a tedious and troublesome process, from the root or rhizome of the *Canna coccinea*, although this botanical origin is altogether uncertain.

Canna starch is in the form of a light, beautifully white powder, of a shining appearance, very unlike the ordinary forms of fecula. Its granules are said to be larger than those of any other variety of starch in use, being from the 300th to the 200th of an inch in length. Under the microscope they appear ovate or oblong, with numerous regular unequally distant rings; and the circular hilum, which is sometimes double, is usually situated at the smaller extremity. (*Pereira*.) This fecula has the ordinary chemical properties of starch, and forms, when prepared with boiling water, a nutritious and wholesome food for infants and invalids. It may be prepared in the same manner as *Arrow-root*, and is said to form even a stiffer jelly with boiling water. (See *Maranta*.) W.

CANTHARIS. U. S., Lond., Ed.

Spanish Flies.

“*Cantharis vesicatoria*.” U. S., Lond., Ed.

Off. Syn. CANTHARIS VESICATORIA. Dub.

Cantharide, Fr.; Spanische Fliege, Kantharide, Germ.; Cantarelle, Ital.; Cantharidas, Span.

The term *Cantharis* was employed by the ancient Greek writers to designate many coleopterous insects. Linnæus conferred the title upon a genus in which the officinal blistering fly was not included, and placed this insect in the genus *Meloë*. This latter, however, has been divided by subsequent naturalists into several genera. Geoffroy made the Spanish fly the prototype of a new one which he called *Cantharis*, substituting *Cicindela* as the title of the Linnæan genus which he had thus deprived of its original designation. Fabricius made some alteration in the arrangement of Geoffroy, and substituted *Lytta* for *Cantharis* as the generic title. The former was adopted by the London College, and at one time was in extensive use; but the latter, having been restored by Latreille, is now recognised in the European and American Pharmacopœias, and is universally employed. By this naturalist the vesicating insects were grouped in a small tribe corresponding very nearly with the Linnæan genus *Meloë*, and distinguished by the title *Cantharidæ*. This tribe he divided into eleven genera, among which is the *Cantharis*. Two others of these genera, the *Meloë* properly so called, and the *Mylabris*, have been employed as vesicatories. The *Mylabris cichorii* is thought to be one of the insects described by Pliny and Dioscorides under the name of *Cantharides*; and is to this day employed in Italy, Greece, the Levant, and Egypt: and another species, the *M. pustulata*, is applied to the same purpose in China. The *Meloë proscarabæus* and *M. majalis* have been occasionally substituted for cantharides in Europe, and the *M. trianthemæ* is used to a considerable extent in the upper provinces of Hindostan. Several species of *Cantharis*, closely analogous to each other in medical properties, are found in various parts of the world; but the *C. vesicatoria* is the only one recognised by the Pharmacopœias of France and Great Britain. The *C. vittata* has been introduced into that of the United States, and will be noticed under a distinct head. At present we shall confine our observations to the *C. vesicatoria*, or common Spanish fly.

CANTHARIS. Class Insecta. Order Coleoptera. Linn.—Family Tracheilides. Tribe Cantharidæ. Latreille.

Gen. Ch. Tarsi entire; nails bifid; head not produced into a rostrum; elytra flexible, covering the whole abdomen, linear semicylindric; wings perfect; maxillæ with two membranaceous lacinix, the external one acute

within, subuncinate; *antennæ* longer than the head and thorax, rectilinear; first joint largest, the second transverse, very short; *maxillary palpi* larger at tip. *Say.*

Cantharis vesicatoria. Latreille, *Gen. Crust. et Insect.*, tom. ii. p. 220. This insect is from six to ten lines in length, by two or three in breadth, and of a beautiful shining golden-green colour. The head is large and heart-shaped, bearing two thread-like, black, jointed feelers; the thorax short and quadrilateral; the wing-sheaths long and flexible, covering brownish membranous wings. When alive, the Spanish flies have a strong, penetrating, fetid odour, compared to that of mice, by which swarms of them may be detected at a considerable distance. They attach themselves preferably to certain trees and shrubs, such as the white poplar, privet, ash, elder, and lilac, upon the leaves of which they feed. The countries in which they most abound are Spain, Italy, and the South of France; but they are found to a greater or less extent in all the temperate parts of Europe, and in the West of Asia. In the state of larva, they live in the ground and gnaw the roots of plants. They usually make their appearance in swarms upon the trees in the months of May and June, at which period they are collected. The time preferred for the purpose is in the morning at sun-rise, when they are torpid from the cold of the night, and easily let go their hold. Persons with their faces protected by masks and their hands by gloves, shake the trees, or beat them with poles; and the insects are received as they fall upon linen cloths spread underneath. They are then plunged into vinegar diluted with water, or exposed in sieves to the vapour of boiling vinegar, and having been thus deprived of life, are dried either in the sun, or in apartments heated by stoves. This mode of killing the flies by the steam of vinegar is as ancient as the times of Dioscorides and Pliny. In some places they are gathered by smoking the trees with burning brimstone. When perfectly dry, they are introduced into casks or boxes, lined with paper and carefully closed, so as to exclude as much as possible the atmospheric moisture.

Cantharides come chiefly from Spain, Italy, and other parts of the Mediterranean. Considerable quantities are also brought from St. Petersburg, derived originally, in all probability, from the southern provinces of Russia, where the insect is very abundant. The Russian flies are more esteemed than those from other sources. They may be distinguished by their greater size, and their colour approaching to that of copper.

Properties. Dried Spanish flies preserve the form and colour, and, to a certain extent, the disagreeable odour of the living insect. They have an acrid, burning, and urinous taste. Their powder is of a grayish-brown colour, interspersed with shining particles, which are the fragments of the feet, head, and wing-cases. If kept perfectly dry, in well-stopped glass bottles, they will retain their activity for a great length of time. A portion which had been preserved by Van Swieten for thirty years in a glass vessel, was found still to possess vesicating properties. But exposed to a damp air, they quickly undergo putrefaction; and this change takes place most speedily in the powder; hence the insects should either be kept whole, and powdered as they are wanted for use, or, if kept in powder, should be well dried immediately after pulverization, and preserved in air-tight vessels. They should never be purchased in powder, as, independently of the consideration just mentioned, they may in this state be more easily adulterated. But, however carefully managed, cantharides are apt to be attacked by mites, which feed on the interior soft parts of the body, reducing them to powder, while the harder exterior parts are not affected. An idea was at one time

prevalent, that the vesicating property of the insect was not injured by the worm, which was supposed to devour only the inactive portion. But this has been proved to be a mistake. M. Farines, an apothecary of Perpignan, has satisfactorily shown, that though the hard parts left by these mites possess some vesicating power, and the powder produced by them still more, yet the sound flies are much stronger than either. Camphor, which has been recommended as a preservative, does not prevent the destructive agency of the worm.* It is also stated by M. Farines, that when the flies are destroyed by the vapour of pyroligneous acid instead of common vinegar, they acquire an odour which contributes to their preservation. Cantharides will bear a very considerable heat without losing the brilliant colour of their elytra; nor is this colour extracted by water, alcohol, ether, or the oils; so that the powder might be deprived of all its active principles, and yet retain the exterior characters unaltered. The wing cases also resist putrefaction for a long time, and the shining particles have been detected in the human stomach months after interment.

So early as 1778, Thouvenel attempted to analyze cantharides, and the attempt was repeated by Dr. Beaupoil in 1803; but no very interesting or valuable result was obtained till the year 1810, when Robiquet discovered in them a crystalline substance, which appears to be the vesicating principle of the insect, and to which Dr. Thomson gave the name of *cantharidin*. The constituents, according to Robiquet, are, 1. a green oil, insoluble in water, soluble in alcohol, and inert as a vesicatory; 2. a black matter, soluble in water, insoluble in alcohol, and inert; 3. a yellow viscid matter, soluble in water and alcohol, and without vesicating powers; 4. *cantharidin*; 5. a fatty matter insoluble in alcohol; 6. phosphates of lime and magnesia, acetic acid, and in the fresh insect a small quantity of uric acid. Orfila has since discovered a volatile principle, upon which the fetid odour of the fly depends. It is separable by distillation with water. *Cantharidin* is a white substance in the form of crystalline scales, of a shining micaceous appearance, insoluble in water and cold alcohol, but soluble in ether, the oils, and in boiling alcohol which deposits it upon cooling. It is fusible and volatilizable by heat without decomposition, and its vapours condense in acicular crystals. It is obtained by submitting the watery extract of cantharides to the action of boiling alcohol, which extracts the yellow matter and the cantharidin. The alcoholic solution is evaporated, and the residue treated repeatedly with sulphuric ether, which dissolves the cantharidin with a small quantity of the yellow matter, and deposits them when allowed to evaporate spontaneously. The yellow matter is separated by cold alcohol; and the cantharidin, being thus left pure, is dried between folds of bibulous paper.†

* It appears from the experiments of M. Nivet, that, though camphor does not preserve the entire fly from the attacks of the larvæ of the *Anthrenus*, it actually destroys the mites of the *Cantharis* so often found in the powder, and may, therefore, be introduced with advantage, in small lumps, into bottles containing powdered cantharides. (*Journ. de Pharm.* xix. 604.) Pereira has found that a few drops of strong acetic acid added to the flies are the best preservative. Perhaps, however, a more effectual means of preserving them, whether whole or in powder, would be the application of the process of Apert, which consists in exposing them, for half an hour, confined in glass bottles, to the heat of boiling water, which destroys the eggs of the insect, without impairing the virtues of the flies. (*Ibid.* xxii. 246.) Of course, the access of water to the flies should be carefully avoided.

† In the *Journal de Pharmacie* for January 1835, a much simpler and more productive method of obtaining cantharidin is described by M. Thierry. It consists in macerating powdered flies in ether for several days; introducing the mixture into an apparatus for filtering by displacement; adding, after the liquid has ceased to flow out, fresh portions of ether, till it comes away nearly colourless; displacing the whole of the menstruum still

Notwithstanding the insolubility of this principle in water and cold alcohol, the decoction and tincture of cantharides have the peculiar medicinal properties of the insect; and Lewis ascertained that both the aqueous and alcoholic extracts acted as effectually in exciting vesication as the flies themselves, while the residue was in each case inert. The cantharidin consequently exists in the insect so combined with the yellow matter as to be rendered soluble in water and cold alcohol. It has been found also in the *Cantharis vittata*, and *Mylabris cichorii*, and probably exists in other vesicating insects.

Adulterations. These are not common. Occasionally other insects are added, purposely, or through carelessness. These may be readily distinguished by their different shape or colour. An account has been published of considerable quantities of variously coloured glass beads having been found in a parcel of flies; but this would be too coarse a fraud to be extensively practised. Pereira states that powdered flies are sometimes adulterated with euphorbium.

Medical Properties and Uses. Internally administered, cantharides are a powerful stimulant, exercising a peculiar influence over the urinary and genital organs. In moderate doses, this medicine sometimes acts as a diuretic, and generally excites some irritation in the urinary passages, which, if its use be persevered in, or the dose increased, often amounts to violent strangury, attended with excruciating pain, and the discharge of bloody urine. In still larger quantities, it produces, in addition to these effects, obstinate and painful priapism, vomiting, bloody stools, severe pains in the whole abdominal region, excessive salivation, with a fetid cadaverous breath, hurried respiration, a hard and frequent pulse, burning thirst, exceeding difficulty of deglutition, sometimes a dread of liquids, frightful convulsions, tetanus, delirium, and death. Orfila has known twenty-four grains of the powder prove fatal. Dissection reveals inflammation and ulceration of the mucous coat of the whole intestinal canal. Notwithstanding their exceeding violence, cantharides have been long and beneficially used in medicine. Either these or other vesicating insects appear to have been given by Hippocrates in cases of dropsy and amenorrhœa, in the latter of which complaints, when properly prescribed, they are a highly valuable remedy. In dropsy they sometimes prove beneficial when the system is in an atonic condition, and the vessels of the kidneys feeble. Dr. Ferriar considers them peculiarly useful in the anasarcaous swellings which occasionally succeed scarlet fever. They are also useful in obstinate gleet, leucorrhœa, and seminal weakness; and afford one of the most certain means of relief in incontinence of urine arising from debility or partial paralysis of the sphincter of the bladder. A case of diabetes is recorded in the *N. Am. Archives*, (vol. ii. p. 175,) in which a cure was effected under the use of tincture of cantharides. They are used also in certain cutaneous eruptions, especially those of a scaly character, and in chronic eczema. Their unpleasant effects upon the urinary passages are best obviated by the free use of diluent drinks; and, when not consequent upon great abuse of the medicine, may almost always be relieved by an anodyne injection composed of laudanum

remaining in the mass by pouring water upon it; distilling the filtered liquor so as to recover the ether; then allowing the residue to cool; and finally purifying the cantharidin which is deposited, by treating it with boiling alcohol and animal charcoal. Alcohol of 34°, or a mixture of alcohol and ether, may be substituted for the ether itself; but the last mentioned fluid is preferable, as it dissolves less of the green oil, the separation of which from the cantharidin is the most difficult part of the process. M. Thierry obtained from 1000 parts of powdered flies, 4 parts of pure cantharidin.

with a small quantity of mucilaginous fluid. The dose of Spanish flies is one or two grains of the powder, which may be given twice a day in the form of pill. The tincture, however, is more frequently employed.

Externally applied, cantharides excite inflammation in the skin, which terminates in a copious secretion of serum under the cuticle. Even thus applied, they not unfrequently give rise to strangury or tenesmus; and this in fact is one of the most troublesome attendants upon their operation. It probably results from the absorption of the active principle of the fly; and is not prevented by any of the various modes of combination in which the epispastic substance has been applied. Camphor given internally, or mixed with the flies previously to their application, was at one time in much repute as a preventive of strangury, but has lost its credit. The most certain method of obviating this unpleasant effect, is to allow the epispastic application to continue no longer than is necessary to its full rubefacient operation; and afterwards to favour vesication by the use of an emollient poultice. (See *Unguentum Cantharidis*.)

The blistering fly may be employed either as a rubefacient, or with a view to the production of a blister. In the former capacity it is seldom used, except in low states of disease, where external stimulation is required to support the system; but as an epispastic, it is preferred to all other substances, and in the extent of its employment is surpassed by few articles of the *Materia Medica*.

Blisters are calculated to answer numerous indications. Their local effect is attended with a general excitement of the system, which renders them valuable auxiliaries to internal stimulants in low or typhoid conditions of disease; and they may sometimes be safely resorted to with this view when the latter remedies are inadmissible. The powerful impression they make on the system is sufficient in many instances to subvert morbid associations, and thus to allow the re-establishment of healthy action. Hence their application to the cure of remittent and intermittent fevers, in which they often prove effectual, when so employed as to be in full operation at the period for the recurrence of the paroxysm. On the principle of revulsion, they prove useful in a vast variety of complaints. Drawing both the nervous energy and the circulating fluid to the seat of their own immediate action, they relieve irritations and inflammations of internal parts; and are employed for this purpose in every disease attended with these derangements. In such cases, however, arterial excitement should always be reduced by direct depletion before the remedy is resorted to. Blisters are also capable of substituting their action for one of a morbid nature existing in the part to which they are directly applied. Hence their use in tinea capitis, obstinate herpes, and various cutaneous eruptions. Their local stimulation renders them useful in some cases of threatened gangrene, and in partial paralysis. From the serous discharge they occasion, much good results in erysipelas and various other local inflammations, in the immediate vicinity of which their action can be established; and the effects of an issue may be obtained by the continued application of irritants to the blistered surface. Perhaps the pain produced by blisters may be useful in some cases of nervous excitement or derangement, in which it is desirable to withdraw the attention of the patient from subjects of agitating reflection. On some constitutions they produce a poisonous impression, attended with frequent pulse, dryness of the mouth and fauces, heat of skin, subsultus tendinum, and even convulsions; and some physicians have been so much alarmed by the occasional occurrence of these symptoms as to induce them to employ the remedy with great hesitation. What is the precise condition

of system in which these effects result, it is impossible to determine. They probably arise from the absorption of the active principle of cantharides; and depend on idiosyncrasies of constitution, by which the system of certain individuals is susceptible of impressions different from those usually produced by the same cause. In this respect the Spanish flies are analogous to mercury; and any argument drawn from this source against the use of the one would equally apply to the other. The general good which results from their use far overbalances any partial and uncertain evil. For some rules relative to the application of blisters, the reader is referred to the article *Ceratum Cantharidis*.

CANTHARIS VITTATA. U.S.

Potato Flies.

“*Cantharis vittata.*” *U. S.*

Within the limits of the United States are several species of *Cantharis*, which have been employed as substitutes for the *C. vesicatoria*, and found to be equally efficient. Of these, only the *C. vittata* has been adopted as officinal; but as others may be more abundant in particular districts, or in certain seasons, and are not inferior in vesicating powers, we shall briefly notice all which have been submitted to experiment.

1. *Cantharis vittata*. Latreille, *Gen. Crust. et Insect.*; Durand, *Journ. of the Phil. Col. of Pharm.* ii. 274. fig. 4. The *potato fly* is rather smaller than the *C. vesicatoria*, which it resembles in shape. Its length is about six lines. The head is of a light red colour, with dark spots upon the top; the feelers are black; the elytra or wing cases are black, with a yellow longitudinal stripe in the centre, and with a yellow margin; the thorax is also black, with three yellow lines; and the abdomen and legs, which have the same colour, are covered with a cinereous down. It inhabits chiefly the potato vine, and makes its appearance about the end of July or beginning of August, in some seasons, in great abundance. It is found on the plant in the morning and evening, but during the heat of the day descends into the soil. The insects are collected by shaking them from the plant into hot water; and are afterwards carefully dried in the sun. They are natives of the Middle and Southern States.

This species of *Cantharis* was first described by Fabricius in the year 1781; and was introduced to the notice of the profession by Dr. Isaac Chapman of Bucks county, Pennsylvania, who found it equal if not superior to the Spanish fly as a vesicatory. The testimony of Dr. Chapman has been corroborated by that of many other practitioners, some of whom have even gone so far as to assert, that the potato fly is not attended in its action with the inconvenience of producing strangury. But this statement has been ascertained to be incorrect, and as the vesicating property of all these insects probably depends upon the same proximate principle, their operation may be considered as identical in other respects. If the potato fly has been found more speedy in its effects than the *Cantharis* of Spain, the result is perhaps attributable to the greater freshness of the former. It may be applied to the same purposes, treated in the same manner, and given in the same dose as the foreign insect.

2. *Cantharis cinerea*. Latreille, *Gen. Crust. et Insect.*; Durand, *Journ. of the Phil. Col. of Pharm.* i. 274. fig. 5. The ash-coloured cantharis closely resembles the preceding species in figure and size; but differs from it in colour. The elytra and body are black, without the yellow stripes that characterize the *C. vittata*, and are entirely covered with a short and dense ash-coloured down, which conceals the proper colour of the insect. The feelers are black, and the first and second joints are very large in the male. This species also inhabits the potato vine, and is occasionally found on other plants, as the English bean and wild indigo. It is a native of the Northern and Middle States. All the remarks before made upon the potato fly, as to the mode of collection, properties, and medical use, apply equally well to that at present under consideration. Illiger in 1801 first discovered its vesicating properties; but to Dr. Gorham is due the credit of calling public attention particularly to the subject, in a communication addressed, in the year 1808, to the Medical Society of Massachusetts. This species is often confounded with the *C. vittata*.

3. *Cantharis marginata*. Latreille, *Gen. Crust. et Insect.*; Durand, *Journ. of the Phil. Col. of Pharm.* ii. 274. fig. 6. This is somewhat larger than the *C. vittata*, and of a different shape. The elytra are black, with the suture and margin ash-coloured. The head, thorax, and abdomen are black, but nearly covered with an ash-coloured down; and on the upper part of the abdomen, under the wings, are two longitudinal lines of a bright clay colour. This species is usually found, in the latter part of summer, upon the different plants belonging to the genus *Clematis*, and frequents especially the lower branches which trail along the ground. Professor Woodhouse of Philadelphia first ascertained the vesicating properties of this insect; but it had previously been described by Fabricius as a native of the Cape of Good Hope. Dr. Harris of Massachusetts found it equally efficient as a vesicatory with any other species of this genus.

4. *Cantharis atrata*. Latreille, *Gen. Crust. et Insect.*; Durand, *Journ. of the Phil. Col. of Pharm.* ii. 274. fig. 7. The black cantharis is smaller than the indigenous species already described; but resembles the *C. marginata* in figure. Its length is only four or five lines. It is distinguished by its size, and by its uniform black colour. It frequents more especially the different species of *Aster* and *Solidago*, though it is found also on the *Prunella vulgaris*, *Ambrosia trifida*, and some other plants. Mr. Durand met with considerable numbers of this insect in the neighbourhood of Philadelphia in the month of September, and they continued to appear till the middle of October. They are common in the Northern and Middle States, but are not confined exclusively to this country, being found also in Barbary. Drs. Oswood and Harris of New-England have experimented with them, and satisfactorily ascertained their vesicating powers. They are probably identical with the insect noticed as vesicatory by Professor Woodhouse, under the name of *Meloë niger*.

Several other species have been discovered in the United States, but not yet practically employed. Among these are the *C. æneas*, a native of Pennsylvania, discovered by Mr. Say; the *C. politus* and *C. aszelianus*, which inhabit the Southern States; the *C. Nuttalli*, a large and beautiful insect of Missouri, first noticed by Mr. Nuttall, and said to surpass the Spanish fly in magnitude and splendour; and the *C. albida*, another large species, found by Mr. Say near the Rocky Mountains. Of these, the *C. Nuttalli** bids fair, at some future period, to be an object of some importance in the

* *Lytta Nuttalli*, Say, Amer. Entomol. vol. i. fig. 3.

western section of this country. The head is of a deep greenish colour, with a red spot in front; the thorax is of a golden green; the elytra, red or golden purple and somewhat rugose on their outer surface, green and polished beneath; the feet black; the thighs, blue or purplish. The exploring party under Major Long ascertained the vesicating powers of this insect. It was found in the plains of the Missouri, feeding on a scanty grass, which it sometimes covered to a considerable extent. In one place it was so numerous and troublesome, as to be swept away by bushels, in order that a place might be cleared for encamping. W.

CAPSICUM. U. S., Lond.

Cayenne Pepper.

“The fruit of *Capsicum annum*.” U. S. “*Capsicum annum*. *Baccæ*.” Lond. “Fruit of *Capsicum annum* and other species.” Ed.

Off. Syn. CAPSICUM ANNUUM. *Capsulæ cum seminibus*. Dub.
Poivre de Guinee, Poivre d'Inde, Fr; Spanischer Pfeffer, Germ.; Pepperone, Ital.; Pimiento, Span.

CAPSICUM. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solanaceæ.

Gen. Ch. Corolla wheel-shaped. Berry without juice. Willd.

Numerous species of *Capsicum*, inhabiting the East Indies and tropical America, are enumerated by botanists, the fruit of which, differing simply in the degree of pungency, may be indiscriminately employed. The *C. baccatum* or bird pepper, and the *C. frutescens* are said to yield most of the Cayenne pepper brought from the West Indies and South America; and Ainslie informs us that the latter is chiefly employed in the East Indies. The species most extensively cultivated in Europe and this country, is that recognised as officinal by the Pharmacopœias, namely, the *C. annum*. The first two are shrubby plants, the last is annual and herbaceous.

Capsicum annum. Willd. *Sp. Plant.* i. 1052; Woodv. *Med. Bot.* p. 226. t. 80. The stem of the annual capsicum is thick, roundish, smooth, and branching; rises two or three feet in height; and supports ovate, pointed, smooth, entire leaves, which are placed without regular order on long foot-stalks. The flowers are solitary, white, and stand on long peduncles at the axils of the leaves. The calyx is persistent, tubular, and five-cleft; the corolla, monopetalous and wheel-shaped, with the limb divided into five spreading, pointed, and plaited segments; the filaments, short, tapering, and furnished with oblong anthers; the germen, ovate, supporting a slender style which is longer than the filaments, and terminates in a blunt stigma. The fruit is a pendulous, pod-like berry, light, smooth and shining, of a bright, scarlet, orange, or sometimes yellow colour, with two or three cells, containing a dry loose pulp, and numerous flat, kidney-shaped, whitish seeds.

The plant is a native of the warmer regions of Asia and America, and is cultivated in almost all parts of the world. It is abundantly produced in this country, both for culinary and medicinal purposes. The flowers appear in July and August, and the fruit ripens in October. Several varieties are cultivated in our gardens, differing in the shape of the fruit. The most abundant is probably that with a large irregularly ovate berry, depressed at the extremity, which is much used in the green state for pickling. The medicinal variety is that with long, conical, generally pointed, recurved fruit, usually not thicker than the finger. Sometimes we meet with small, spherical, slightly compressed berries, not greatly exceeding a large cherry in size.

When perfectly ripe and dry, the fruit is ground into powder, and brought into market under the name of red or Cayenne pepper. Our markets are also partly supplied by importation from the West Indies. A variety of capsicum, consisting of very small, conical, exceedingly pungent berries, has recently been imported from Liberia. In England the fruit of the *C. annum* is frequently called *chillies*.

Powdered capsicum is usually of a more or less bright red colour, which fades upon exposure to light, and ultimately disappears. The odour is peculiar and somewhat aromatic, stronger in the recent than in the dried fruit. The taste is bitterish, acrid, and burning, producing a fiery sensation in the mouth, which continues for a long time. The pungency appears to depend on a peculiar principle, which was obtained, though probably not in a perfectly isolated state, by Braconnot, and named *capsicin*. The fruit, freed from the seeds, was submitted to the action of alcohol, and the resulting tincture evaporated. During the evaporation a red-coloured wax separated, and the residuary liquor by further evaporation afforded an extract, from which ether dissolved the capsicin. This was obtained by evaporating the ether. It resembles an oil or soft resin, is of a yellowish-brown or reddish-brown colour, and when tasted, though at first balsamic, soon produces an insupportably hot and pungent impression over the whole interior of the mouth. Exposed to heat it melts, and at a higher temperature, emits fumes which, even in very small quantity, excite coughing and sneezing. It is slightly soluble in water and vinegar, and very soluble in alcohol, ether, oil of turpentine, and the caustic alkalies, which it renders reddish-brown. It constitutes, according to Braconnot, 1.9 per cent. of the fruit. The other ingredients, as ascertained by the same chemist, are colouring matter, an azotized substance, gum, pectic acid (probably pectin), and saline matters. It is said that the red oxide of lead is sometimes added to the powdered capsicum sold in Europe. It may be detected by digesting the suspected powder in diluted nitric acid, filtering, and adding a solution of sulphate of soda, which will throw down a white precipitate if there be any oxide of lead present.

Medical Properties and Uses. Cayenne pepper is a powerful stimulant, producing when swallowed a sense of heat in the stomach, and a general glow over the body, without any narcotic effect. Its influence over the circulation, though considerable, is not in proportion to its local action. It is much employed as a condiment, and proves highly useful in correcting the flatulent tendency of certain vegetables, and bringing them within the digestive powers of the stomach. Hence the advantage derived from it by the natives of tropical climates who live chiefly on vegetable food. In the East Indies it has been used from time immemorial. From a passage in the works of Pliny, it appears to have been known to the Romans. As a medicine it is useful in cases of enfeebled and languid stomach, and is occasionally prescribed in dyspepsia and atonic gout, particularly when attended with much flatulence, or occurring in persons of intemperate habits. It has also been given as a stimulant in palsy and certain lethargic affections. To the sulphate of quinia it forms an excellent addition in some cases of intermittents, in which there is a great want of gastric susceptibility. It acts by exciting the stomach, and rendering it sensible to the influence of the tonic. Upon the same principle it may prove useful in low forms of fever as an adjuvant to tonic or stimulant medicines. Its most important application, however, is to the treatment of malignant sore throat and scarlet fever, in which it is used both internally and as a gargle. No other remedy has obtained equal credit in these complaints. The following formula was em-

ployed in malignant scarlatina with great advantage in the West Indies, where this application of the remedy originated. Two tablespoonfuls of the powdered pepper, with a teaspoonful of common salt, are infused for an hour in a pint of a boiling liquid composed of equal parts of water and vinegar. This is strained when cool through a fine linen cloth, and given in the dose of a tablespoonful every half hour. The same preparation is also used as a gargle. It is, however, only to the worst cases that the remedy is applied so energetically. In milder cases of scarlatina with inflamed or ulcerated throat, much relief and positive advantage often follow the employment of the pepper in a more diluted state. Capsicum has also been advantageously used in sea-sickness, in the dose of a teaspoonful given in some convenient vehicle on the first occurrence of nausea.

Applied externally, capsicum is a powerful rubefacient, very useful in local rheumatism, and in low forms of disease, where a stimulant impression upon the surface is demanded. It has the advantage, under these circumstances, of acting speedily without endangering vesication. It may be applied in the form of cataplasm, or more conveniently and efficiently as a lotion mixed with heated spirit. The powder or tincture, brought into contact with a relaxed uvula, often acts very beneficially.

The dose of the powder is from five to ten grains, which may be most conveniently given in the form of pill. Of an infusion prepared by adding two drachms to half a pint of boiling water, the dose is about half a fluidounce. A gargle may be prepared by infusing half a drachm of the powder in a pint of boiling water, or adding half a fluidounce of the tincture to eight fluidounces of rose-water.

CARBO.

Carbon.

Pure charcoal; *Carbone, Fr., Ital.*; *Kohlenstoff, Germ.*; *Carbon, Span.*

Carbon is an elementary substance of great importance, and very extensively diffused in nature. It exists in large quantity in the mineral kingdom, and forms the most abundant constituent of animal and vegetable matter. In a state of perfect purity and crystallized, it constitutes the diamond, and more or less pure, it forms the substances known under the names of plumbago or black lead, anthracite, bituminous coal, coke, animal charcoal, and vegetable charcoal. Combined with oxygen, it constitutes *carbonic acid*, which is a constituent of the atmosphere, and present in many natural waters, especially those which have an effervescing quality. United with oxygen and a base, it forms the carbonates, and of course *carbonate of lime*, which is one of the most abundant combinations of the mineral kingdom.

The *diamond*, or crystallized carbon, is found principally in India and Brazil. It is perfectly transparent, and the hardest and most brilliant substance in nature. Its sp. gr. is about 3.5. It is perfectly fixed and unalterable in the fire, provided air be completely excluded; but it is combustible in air or oxygen, the product being the same as when charcoal is burned, namely carbonic acid.

Next to diamond, plumbago and anthracite are the purest natural forms of carbon. *Plumbago* is the substance of which black lead crucibles and pencils are made. It is found in greatest purity, perhaps, in the mine of Borrowdale, in England; but it also occurs very pure in this country, especially

near Bustleton, in Pennsylvania. It was formerly supposed to be a carburet of iron; but in very pure specimens it is nearly free from iron, which must, therefore, be deemed an accidental impurity. *Anthracite* occurs in different parts of the world, but particularly in the United States. Immense beds of it exist in Pennsylvania. *Bituminous coal* is a form of the carbonaceous principle, in which the carbon is associated with volatile matter of a bituminous nature. When this is driven off by the process of charring, as in the manufacture of coal gas, a kind of mineral charcoal, called *coke*, is obtained, very useful in the arts as a fuel.

Carbon may be obtained artificially, in a state approaching to purity, by several processes. One method is to expose lampblack to a full red heat in a close vessel. It may also be obtained in a very pure state by passing the vapour of volatile oils through an ignited porcelain tube; whereby the hydrogen and oxygen of the oil will be dissipated, and the charcoal left in the tube. A very pure charcoal is procured by exposing sugar, or other vegetable substances which leave no ashes when burnt, to ignition in close vessels.

Properties. Carbon in its crystallized form has already been described as diamond. In its uncrystallized state it is an insoluble, infusible solid, generally of a black colour, and without taste or smell. It burns when sufficiently heated, uniting with the oxygen of the air, and generating a gaseous acid, called carbonic acid. Its sp. gr. in the solid state, apart from the pores which it contains when in mass, is 3.5; but with the pores included, it is only 0.44. In a state of vapour, its density is 0.4215, as obtained by calculation. It is a very unalterable and indestructible substance, and has great power in resisting and correcting putrefaction in other bodies. When in a state of extreme division, it possesses the remarkable property of destroying the colouring and odorous principles of most liquids. The conditions, under which this property is most powerfully developed, will be explained under the head of animal charcoal. (See *Carbo Animalis*.) Its other physical properties differ according to its source and peculiar state of aggregation. Its equivalent number is 6.12, and its symbol C. As a chemical element, it enjoys a very extensive range of combination. It combines in five proportions with oxygen, forming carbonic oxide, and carbonic, oxalic, mellitic, and croconic acids. (See *Aqua Acidi Carbonici*, and *Oxalic Acid*.) It unites also with chlorine, iodine, and bromine. With hydrogen it forms a number of compounds, called *carbo-hydrogens*, of which the most interesting, excluding hypothetical radicals, are light carburetted hydrogen, or fire damp, olefiant gas, the light and concrete oils of wine, and certain purified volatile oils. With nitrogen it constitutes cyanogen, the compound radical of hydrocyanic or prussic acid; and united with iron in minute proportion it forms steel. It is thus perceived, that as a chemical agent it performs an important part in the economy of nature.

To notice all the forms of the carbonaceous principle would be out of place in this work. We shall, therefore, restrict ourselves to the consideration of those which are officinal, namely, *animal charcoal*, and *wood charcoal*. These will be described in the two following articles. B.

CARBO ANIMALIS. U.S., Lond., Ed.

Animal Charcoal.

“Charcoal prepared from bones.” U. S. “Carbo. *Ex carne et ossibus coctus.*” Lond. “Impure animal charcoal obtained commonly from bones.” Ed.

Charbon animal, *Fr.*; Thierische Kohle, *Germ.*; Carbone animale, *Ital.*; Carbon animal, *Span.*

The animal charcoal employed in pharmacy and the arts, is obtained from bones, by subjecting them to a red heat in close vessels, and is chiefly employed as a decolorizing agent. The residue of the ignition is a black matter, which, when reduced to powder, forms the substance properly called *bone-black*, but familiarly known under the incorrect name of *ivory-black*. Ivory by carbonization will furnish a black, which, on account of its fineness and intensely black colour, is more esteemed than the ordinary bone-black; but it is much more expensive.

Animal charcoal, in the form of bone-black, is extensively manufactured for the use of sugar refiners and others; and an ammoniacal liquor, called *bone spirit*, is obtained as a secondary product, and sold to the makers of sal ammoniac. The bones are subjected to destructive distillation in iron retorts or cylinders, and when the bone spirit ceases to come over, the residuum is charred bone, or bone-black. Bone consists of animal matter with phosphate and carbonate of lime. In consequence of a new arrangement of the elements of the animal matter, the hydrogen and nitrogen united as ammonia, and a part of the charcoal as carbonic acid, distil over; while the remainder of the charcoal is left in the retort, intermingled with the calcareous salts. In this form, therefore, of animal charcoal, the carbon is mixed with phosphate and carbonate of lime; and the same is the case with the true ivory-black.

Properties. Animal charcoal, in the form of bone-black, (called ivory-black in the shops,) is a black powder, possessing a slightly alkaline and bitterish taste, and having a general resemblance to powdered vegetable charcoal. It is, however, more dense and less combustible than this charcoal, from which, moreover, it may be distinguished by burning a small portion of it on a red-hot iron, when it will leave a residuum imperfectly acted on by sulphuric acid; whereas the ashes from vegetable charcoal will readily dissolve in this acid, forming a bitterish solution.

Animal charcoal by no means necessarily possesses the decolorizing property, as this depends upon its peculiar state of aggregation. If a piece of pure animal matter be carbonized, it usually enters into fusion, and, from the gaseous matter which is extricated, becomes porous and cellular. The charcoal formed has generally a metallic lustre, and a colour resembling that of black lead. It has, however, little or no decolorizing power, even though it may be finely pulverized.

Rationale of the Effects of Charcoal as a Decolorizing Agent. The decolorizing power of charcoal was first noticed by Lowitz of St. Petersburg; and the subject was subsequently ably investigated by Bussy, Payen, and Desfosses. It is generally communicated to charcoal by igniting it in close vessels, but not always. The kind of charcoal, for example, obtained from substances which undergo fusion during carbonization, does not possess the property, even though it may be afterwards finely pulverized. The property in question is possessed to a certain extent by wood charcoal; but

is developed in it in a much greater degree by burning it with some chemical substance, which may have the effect of reducing it to an extreme degree of fineness. The most powerful of all the charcoals for discharging colours, are those obtained from certain animal matters, such as dried blood, hair, horns, hoofs, &c. by first carbonizing them in connexion with carbonate of potassa, and then washing the product with water. Charcoal thus prepared, seems to be reduced to its finest possible particles. The next most powerful decolorizing charcoal is *ivory* or *bone-black*, in which the separation of the carbonaceous particles is effected by the phosphate of lime present in the bone. Vegetable substances also may be made to yield a good charcoal for destroying colour, provided, before carbonization, they be well comminuted, and mixed with pumice stone, chalk, flint, calcined bones, or other similar substance, in a pulverized state.

It results from the foregoing facts, that the decolorizing power of charcoal depends upon a peculiar mode of aggregation of its particles, the leading character of which is that they are isolated from one another, and thus enabled to present a greater extent of surface. It is on this principle that certain chemical substances act in developing the property in question, when they are ignited in a state of intimate mixture with the substance to be charred. Thus it is perceived that there is no necessary connexion between animal charcoal and the decolorizing power; as this charcoal may or may not possess the peculiar aggregation of its particles on which the power depends. Bone-black, for instance, has this property, not because it is an animal charcoal; but, because, in consequence of the phosphate of lime present in the bone, the favourable state of aggregation is induced. Of all the substances yet tried to separate the carbonaceous molecules, carbonate of potassa appears to be the best.

The following table, abridged from one drawn up by Bussy, denotes the decolorizing power of different charcoals, compared with the effect of bone-black taken as unity.

KINDS OF CHARCOAL.	Decolorizing	Decolorizing
	Power relative to Syrup.	Power relative to Indigo.
Bone-black,	1	1
Bone charcoal treated by an acid,	1.6	1.87
Oil ignited with phosphate of lime,	1.9	2
Lampblack, not ignited,	3.3	4
Charcoal from acetate of potassa,	4.4	5.6
Gluten ignited with carbonate of potassa,	8.8	10.6
Blood ignited with phosphate of lime,	10	12
Lampblack ignited with carbonate of potassa,	10.6	12.2
Blood ignited with chalk,	11	18
White of egg ignited with carbonate of potassa,	15.5	34
Glue ignited with carbonate of potassa,	15.5	36
Bone charcoal, formed by depriving the bone of phosphate of lime by an acid, and ignition with potassa,	20	45
Blood ignited with carbonate of potassa,	20	50

Comparing the extremes of this table, it is perceived that blood ignited with carbonate of potassa is twenty times more powerful in discharging the colour of syrup, and fifty times more powerful in decolorizing indigo, than an equal weight of bone-black. This is certainly a great disparity in effect, and could hardly have been anticipated.

Bone-black consists, in the hundred parts, of eighty-eight parts of phosphate and carbonate of lime, ten of charcoal, and two of carburet or silicuret of iron. (*Dumas.*) The proportion of charcoal, here given, is small. According to Dr. Christison, Scotch bone-black generally yields about twenty per cent. of charcoal, which is a large amount to be obtained by analysis, considering that thirty-three per cent. only of the bone is animal matter, and that part of the charcoal is lost in the process.

Pharmaceutical Uses, &c. Animal charcoal is used in pharmacy for decolorizing vegetable principles, such as quinia, morphia, &c., and in the arts, principally for clarifying syrups in sugar refining, and for depriving spirits distilled from grain of the peculiar volatile oil, which imparts to them an unpleasant taste as first distilled. The manner in which it is used is to mix it with the substance to be decolorized, and to allow the mixture to stand for some time. The charcoal unites chemically with the colouring matter, and the solution by filtration is obtained white and transparent. For most pharmaceutical operations, animal charcoal should be purified by muriatic acid from phosphate and carbonate of lime. (See *Carbo Animalis Purificatus.*) In the United States formula for sulphate of quinia, however, it is used without purification; as the carbonate of lime which it contains performs a useful part in the process. (See *Quiniæ Sulphas.*)

CARBO LIGNI. *U. S., Lond., Ed., Dub.*

Charcoal.

Charbon de bois, *Fr.*; Holzkohle, *Germ.*; Carbone di legno, *Ital.*; Carbon de lena, *Span.*

Preparation on the Large Scale. Billets of wood are piled in a conical heap, and covered with earth and sod to prevent the free access of air; several holes being left at the bottom, and one at the top of the heap, in order to produce a draught to commence the combustion. The wood is then kindled from the bottom. In a little while, the hole at the top is closed, and after the ignition is found to pervade the whole heap, those at the bottom are stopped also. The combustion taking place with a smothered flame and limited access of air, the volatile portions of the wood, consisting of hydrogen and oxygen, are dissipated, while the carbon, in the form of charcoal, is left behind.

In this process for the carbonization of wood, all the volatile products are lost; and a portion of the charcoal itself is dissipated by combustion. Wood, thus carbonized, yields not more than 17 or 18 per cent. of charcoal. A better method is to char the wood in iron cylinders, when it yields from 22 to 23 parts in the 100 of excellent charcoal; and at the same time, the means are afforded for collecting the volatile products, consisting of pyroligneous acid, empyreumatic oil, and tar. This process for obtaining charcoal has been described under another head. (See *Acidum Pyroligneum.*)

Preparation for Medical Use. Common charcoal is not, perhaps, sufficiently pure for medical exhibition; as all the volatile portions of the wood are not completely expelled. Lowitz directs its purification to be conducted in the following manner. Fill a crucible with ordinary charcoal reduced to fine powder, and lute on a perforated cover. Then expose the whole to a strong red heat, and continue the ignition as long as a blue flame issues from the aperture in the cover. When this ceases, allow the charcoal to cool, and transfer it quickly to bottles, which must be well stopped.

Properties. Charcoal is a black, shining, brittle, porous substance, tasteless and inodorous, and insoluble in water. It is a good conductor of electricity, but a bad one of heat. In masses, it floats in water; but when reduced to a fine powder, whereby its porosity is destroyed, it sinks in that liquid. It possesses the remarkable property of absorbing many times its own bulk of certain gases, provided it be perfectly dry. When exposed to the air after ignition, it increases rapidly in weight, absorbing from twelve to fourteen per cent. of moisture. As ordinarily prepared, it contains the incombustible part of the wood, amounting to one or two per cent., which is left in the form of ashes when the charcoal is burnt. These may be removed by digesting the charcoal in diluted muriatic acid, and afterwards washing it thoroughly on a filter with boiling water.

Medical Properties, &c. Powdered charcoal is antiseptic and absorbent. It is employed with advantage in certain forms of dyspepsia, attended with fetid breath and putrid eructations; and it has been exhibited in dysentery with the effect of correcting the fetor of the stools. As a remedy in obstinate constipation, Dr. Daniel, of Savannah, speaks of it in high terms, and reports fourteen or fifteen cases, in which it proved successful. He also found it useful in the nausea and confined state of the bowels which usually attend pregnancy. Its use as an ingredient of poultices is noticed under the title of *Cataplasma Carbonis Ligni*. Several of its varieties constitute the best tooth powder that can be used. Those which are generally preferred are the charcoals of the cocoa-nut shell and of bread. The dose of charcoal varies from twenty grains to a drachm or more. Dr. Daniel gave it, in his cases, in doses of a tablespoonful repeated every half hour.

In consequence of the absorbent and antiseptic properties of charcoal, it is invaluable in domestic economy. Meat embedded in it in close vessels is kept perfectly sweet for many months; and water intended for long voyages is equally preserved by the addition of its powder. The power of some of its varieties in destroying colours and odours is very considerable; and it acts upon the principle which has been explained under the head of animal charcoal. (See *Carbo Animalis*.)

Charcoal is used in preparing the Edinburgh *Barytæ Murias*, when obtained from the sulphate of baryta.

CARDAMINE. *Lond.*

Cuckoo-flower.

“*Cardamine pratensis. Flores.*” *Lond.*

Off. Syn. CARDAMINE PRATENSIS. *Flores. Dub.*

Cresson des prés, Fr.; Wisenkresse, Germ.; Kardamine, Ital.

CARDAMINE. *Sex. Syst.* Tetradynamia Siliquosa.—*Nat. Ord.* Brassicææ or Cruciferaæ.

Gen. Ch. Pods opening elastically, with revolute valves. *Stigma* entire. *Calyx* somewhat gaping. *Willd.*

Cardamine pratensis. Willd. *Sp. Plant.* iii. 487; Woodv. *Med. Bot.* p. 398. t. 144. The Cuckoo-flower is a perennial herbaceous plant, with a simple, smooth, erect stem, about a foot in height. The leaves are pinnate; the radical, composed of roundish irregularly toothed leaflets, those of the stem alternate, with leaflets which become narrower, more entire, and pointed as they ascend. The flowers are purplish-white or rose-coloured, and terminate the stem in a raceme approaching the character of a corymb.

This species of Cardamine is a native of Europe, and is found in the northern parts of our continent, about Hudson's Bay. It is a very handsome plant, abounding in moist meadows, which it adorns with its flowers in the months of April and May. The leaves are bitterish and slightly pungent, resembling in some measure those of water-cresses, and like them supposed to be possessed of antiscorbutic properties. In Europe they are sometimes added to salads. The flowers only are officinal. They have the same taste with the leaves, and, when fresh, a somewhat pungent odour. When dried, they become inodorous and nearly insipid.

They formerly possessed the reputation of being diuretic, and since the publication of a paper by Sir George Baker, somewhat more than half a century ago, have been occasionally used as an antispasmodic in various nervous diseases, such as chorea and spasmodic asthma, in which they were successfully employed by that physician. They produce, however, little obvious effect upon the system, and are not employed in this country.

The subject of cardamom has been involved in some confusion and uncertainty, both in its commercial and botanical relations. The name has been applied to the aromatic capsules of various Indian plants belonging to the family of the Scitamineæ. Three varieties have long been designated by the several titles of the *lesser*, *middle*, and *larger*, the *cardamomum minus*, *medium*, and *majus*, of older authors; but these terms have been used differently by different writers, so that their precise signification remained doubtful. Pereira, whose position in the midst of the greatest drug market in the world has given him excellent opportunities, which he has not neglected, of investigating the commercial history of drugs, has enabled us in great measure to clear up this confusion. It is well known that the *lesser cardamom*, of most writers, is the variety recognised by the Pharmacopœias, and generally kept in the shops. The other varieties, though circulating to a greater or less extent in European and Indian commerce, are little known in this country. A sketch of the non-official cardamoms, condensed from the account of Pereira, is given below in a note.* The following remarks have reference exclusively to the genuine Malabar or officinal cardamom.

* 1. *Ceylon Cardamom*. This has been denominated variously by different authors, *cardamomum medium*, *cardamomum majus*, and *cardamomum longum*, and is sometimes termed in English commerce *wild cardamom*. It is the *large cardamom* of Guibourt. It is probably derived from a plant cultivated in Candy, in the island of Ceylon, which belongs to the same genus as that producing the officinal cardamom, and is specifically designated by Sir James Edward Smith, *Elettaria major*. It is a lanceolate-oblong, acutely triangular capsule, somewhat curved, about an inch and a half long and four lines broad, with flat and ribbed sides, tough and coriaceous, brownish or yellowish-ash coloured, having frequently at one end the long, cylindrical, three lobed calyx, and at the other the fruit stalk. It is three-celled, and contains angular, rugged, yellowish-red seeds, of a peculiar

Linnæus confounded, under the name of *Amomum Cardamomum*, two different vegetables—the genuine plant of Malabar, and another growing in Java. These were separated by Willdenow, who conferred on the former Sonnerat's title of *Amomum repens*, while he retained the original name for the latter, though not the true cardamom plant. In the tenth vol. of the Linn. Transactions, A. D. 1811, Mr. White, a British Army Surgeon in India, published a very minute description of the Malabar plant, which he had enjoyed frequent opportunities of examining in its native state. From this description, the learned Dr. Maton inferred that the plant, according to Roscoe's arrangement of the Scitamineæ, could not be considered an *Amomum*; and as he was unable to attach it to any other known genus, he proposed to construct a new one, with the name of *Elettaria*, derived from *elettari*, or *ela-tari*, the Malabar name of this vegetable. Sir James Smith afterwards suggested the propriety of naming the new genus *Matonia*, in honour of Dr. Maton; and the latter title having been adopted by Roscoe, obtained a place in former editions of the London and United States Pharmacopœias. After all, however, it is doubtful whether the new genus is well founded; and the celebrated Dr. Roxburgh describes the Malabar cardamom plant as an *Alpinia*, with the specific appellation of *A. Cardamo-*

fragrant odour, and spicy taste. Its effects are analogous to those of the officinal cardamom, which, however, commands three times its price.

2. *Round Cardamom*. This is probably the *Ἀμαμον* of Dioscorides, and the *Amomi ura* of Pliny, and is believed to be the fruit of the *Amomum Cardamomum* (Willd.), growing in Sumatra, Java, and other East India islands. The capsules are usually smaller than a cherry, roundish or somewhat ovate, with three convex sides, more or less striated longitudinally, yellowish or brownish-white, and sometimes reddish, with brown, angular, cuneiform shrivelled seeds, which have an aromatic camphorous flavour. They are sometimes, though very rarely, met with connected together in their native clusters, constituting the *Amomum racemosum*, or *Amome en grappes* of the French Codex. They are similar in medicinal properties to the officinal cardamom, but are seldom used except in the southern parts of Europe.

3. *Java Cardamom*. The plant producing this variety is supposed to be the *Amomum maximum* of Roxburgh, growing in Java and other Malay islands, and said to be cultivated in the mountains of Nepaul. The product of the latter site is called *Nepaul* or *Bengal cardamoms* in the East. The capsules are oval, or oval-oblong, often somewhat ovate, from eight to fifteen lines long and from four to eight broad, usually flattened on one side and convex on the other, sometimes curved, three-valved, and occasionally imperfectly three-lobed, of a dirty grayish-brown colour, and coarse fibrous appearance. They are strongly ribbed, and, when soaked in water, exhibit from nine to thirteen ragged membranous wings, which distinguish them from all other varieties. The seeds have a feebly aromatic taste and smell. This variety of cardamom affords but a very small proportion of volatile oil, is altogether of inferior quality, and when imported into London is usually sent to the continent.

4. *Madagascar Cardamom*. This is the *Cardamomum majus* of Geiger and some other authors, and is thought to be the fruit of the *Amomum angustifolium* of Sonnerat, which grows in marshy grounds in Madagascar. The capsule is ovate, pointed, flattened on one side, striated, with a broad circular scar at the bottom, surrounded by an elevated, notched, and corrugated margin. The seeds have an aromatic flavour analogous to that of the officinal cardamom.

5. *Grains of Paradise*. *Grana Paradisi*. Under this name, and that of *Guinea grains*, are kept in the shops small seeds of a round or ovate form, often angular and somewhat cuneiform, minutely rough, brown externally, white within, of a feebly aromatic odour when rubbed between the fingers, and of a strongly hot and peppery taste. They are brought from Guinea, and are of uncertain botanical origin, though differently referred to the *Amomum Grana Paradisi*, and the *A. melegueta* of Roscoe. Their effects on the system are analogous to those of pepper; but they are seldom used except in veterinary practice, and to give artificial strength to spirits, wine, beer and vinegar.

Other products of different Scitamineæ, which have received the name of cardamom, are described by Pereira; but the above are all that are known in commerce, or likely to be brought into our drug markets.

um. He has been followed by Sprengel, and several other German authorities, and recently by the London College, and the framers of the Pharmacopœia of the United States. Lindley and Pereira, however, adhere to the genus *Elettaria* of Dr. Maton. Finally, Roscoe has arranged the plant with the abandoned genus *Renealmia* of Linnæus which he has restored; and the Edinburgh College has recognised this arrangement in their last edition. In this unsettled state of botanical opinion, we shall follow the authority of Roxburgh.

ALPINIA. *Sex. Syst.* Monandria Monogynia.—*Nat. Ord.* Scitamineæ. *Brown.* Zingiberacæ. *Lindley.*

Gen. Ch. Corolla with interior border unilabiate. *Anther* double, naked, (uncrowned). *Capsule* berried, three-celled. *Seeds* a few, or numerous, arilled. *Roxburgh, Asiat. Research.* vol. xi. p. 350.

Alpinia Cardamomum. Roxburgh.—*Elettaria Cardamomum.* Maton.—*Matonia Cardamomum.* Roscoe.—*Amomum Repens.* Sonnerat; Willd. *Sp. Plant.* i. 9. *Renealmia Cardamomum.* Roscoe, *Monandrous Plants.* Figured in *Linn. Trans.* x. 248. The cardomom plant has a tuberous horizontal root or rhizoma, furnished with numerous fibres, and sending up from eight to twenty erect, simple, smooth, green and shining, perennial stems, which rise from six to twelve feet in height, and bear alternate sheathing leaves. These are from nine inches to two feet long, from one to five inches broad, elliptical-lanceolate, pointed, entire, smooth and dark-green on the upper surface, glossy and pale sea-green beneath, with strong midribs, and short footstalks. The scape or flower-stalk proceeds from the base of the stem, and lies upon the ground, with the flowers arranged in the form of a panicle. The calyx is monophyllous, tubular, and toothed at the margin; the corolla monophyllous and funnel-shaped, with the inferior border unilabiate, three-lobed, and spurred at the base. The fruit is a three-celled capsule, containing numerous seeds.

This valuable plant is a native of the mountainous regions of Malabar, where it springs up spontaneously in the forests after the removal of the undergrowth. From time immemorial great numbers of the natives have depended for a livelihood upon its cultivation. It begins to yield fruit at the end of the fourth year, and continues to bear for several years afterwards. The capsules when ripe are picked from the fruit stems, dried over a gentle fire, and separated by rubbing with the hands from the footstalks and adhering calyx.

Thus prepared, they are ovate-oblong, from three to ten lines long, from three to four thick, three-sided with rounded angles, obtusely pointed at both ends, longitudinally wrinkled, and of a yellowish-white colour. The seeds which they contain are small, angular, irregular, rough as if embossed upon their surface, of a brown colour, easily reduced to powder, and thus separable from the capsules, which, though slightly aromatic, are much less so than the seeds, and should be rejected when the medicine is given in substance. The seeds constitute about 74 parts by weight in the hundred. According to Pereira, three varieties are distinguished in British commerce:—1. the *shorts*, from three to six lines long, from two to three broad, browner and more coarsely ribbed, and more highly esteemed than the other varieties;—2. the *long-longs*, from seven lines to an inch in length by two or three lines in breadth, elongated, and somewhat acuminate; and 3. *short-longs*, which differ from the second variety in being somewhat shorter and less pointed. The odour of cardamom is fragrant, the taste warm, slightly pungent, and highly aromatic. These properties are extracted by water and alcohol, but more readily by the latter. They depend

on a volatile oil which rises with water in distillation. The seeds contain, according to Trommsdorff, 4·6 per cent. of volatile oil, 10·4 of fixed oil, 2·5 of a salt of potassa mixed with a colouring principle, 3·0 of starch, 1·8 of azotized mucilage, 0·4 of yellow colouring matter, and 77·3 of ligneous fibre. The volatile oil is colourless, of an agreeable and very penetrating odour, and of a strong, aromatic, burning, camphorous, and slightly bitter taste. Its sp. gr. is 0·945. It cannot be kept long without undergoing change, and finally, even though excluded from the air, loses its peculiar odour and taste. (Trommsdorff, *Annalen der Pharmacie*, July, 1834.) The seeds should be powdered only when wanted for immediate use, as they retain their aromatic properties best while enclosed within the capsules.

Medical Properties and Uses. Cardamom is a warm and grateful aromatic, less heating and stimulating than some others belonging to the class, and very useful as an adjuvant or corrective of cordial, tonic, and purgative medicines. Throughout the East Indies it is largely consumed as a condiment, and is considered almost among the necessities of life. It was known to the ancients, and derived its name from the Greek language. In this country it is employed chiefly as an ingredient in compound preparations.

Gen. Ch. Corolla somewhat rayed. Florets of the disk abortive. Fruit hispid with hairs. *Willd.*

Daucus Carota. Willd. *Sp. Plant.* i. 1389; Woodv. *Med. Bot.* p. 130. t. 50. The wild carrot has a biennial spindle-shaped root, and an annual, round, furrowed, hairy stem, which divides into long, erect, flower-bearing branches, and rises two or three feet in height. The leaves are hairy, and stand on footstalks nerved on their under side. The lower are large and tripinnate, the upper, smaller and less compound; in both, the leaflets are divided into narrow pointed segments. The flowers are small, white, and

disposed in many-rayed compound umbels, which are at first flat on the top and spreading, but when the seeds are formed, contract so as to present a concave cup-like surface. A sterile flower of a deep purple colour is often observable in the centre of the umbel. The general involucre is composed of several leaves, divided into long narrow segments; the partial is more simple. The petals are five, unequal and cordate. The fruit consists of two plano-convex hispid portions, connected by their flat surface.

The *Daucus Carota* is exceedingly common in this country, growing along fences, and in neglected fields, which in the months of June and July are sometimes white over their whole surface with its flowers. It grows wild also in Europe, from which it is supposed by some botanists to have been introduced into the United States. The well-known garden carrot is the same plant somewhat altered by cultivation. The officinal portions are the fruit of the wild, and the root of the cultivated variety.

1. CARROT SEEDS. Strictly speaking, these should be called the fruit. They are very light, of a brownish colour, of an oval shape, flat on one side, convex on the other, and on their convex surface presenting four longitudinal ridges, to which stiff whitish hairs or bristles are attached. They have an aromatic odour, and a warm, pungent, and bitterish taste. By distillation they yield a pale yellow volatile oil, upon which their virtues chiefly depend. Boiling water extracts their active properties.

Medical Properties and Uses. Carrot seeds are moderately excitant and diuretic, and are considerably employed, both in domestic practice and by physicians, in chronic nephritic affections, and in dropsy. As they possess to a certain extent the cordial properties of the aromatics, they are especially adapted to cases in which the stomach is enfeebled. They are said to afford relief in the strangury from blisters. From thirty grains to a drachm of the bruised seeds may be given at a dose, or a pint of the infusion, containing the virtues of half an ounce or an ounce of the seeds, may be taken during the day. The whole umbel is often used instead of the seeds alone.

2. CARROT ROOT. The root of the wild carrot is whitish, hard, coriaceous, branched, of a strong smell, and an acrid disagreeable taste; that of the cultivated variety is reddish, fleshy, thick, conical, rarely branched, of a pleasant odour, and a peculiar, sweet, mucilaginous taste. The constituents of the root are crystallizable and uncrystallizable sugar, a little starch, extractive, gluten, albumen, volatile oil, vegetable jelly (*pectin* of Braconnot), malic acid, saline matters, lignin, and a peculiar crystallizable, ruby-red, neutral principle, without odour or taste, called *carotin*. In relation to the nature of *vegetable jelly* much uncertainty has existed. By some it has been considered a modification of gum or mucilage combined with a vegetable acid. Braconnot found it to be a peculiar principle, and gave it the name of *pectin*, derived from the Greek word *πηκτις*, and expressive of the peculiar property of gelatinizing, by which it is distinguished. It exists more or less in all vegetables, and is abundant in certain fruits and roots from which jellies are prepared. It may be separated from the juice of fruits by the addition of alcohol, which precipitates it in the form of a jelly. This being washed with weak alcohol and dried, yields a semitransparent substance bearing some resemblance to fish-glue or isinglass. Immersed in 100 parts of cold water, it swells like bassorin, and ultimately forms a homogeneous jelly. With a larger proportion of water it exhibits a mucilaginous consistence. It is less acted on by boiling than by cold water. When perfectly pure it is tasteless and has no effect on vegetable blues. A striking peculiarity is, that by the agency of a fixed alkali or alkaline earthy base it is instantly converted into pectic acid, which unites with the base to form a

pectate. This may be decomposed by the addition of an acid, which unites with the alkali and separates the pectic acid. (Braconnot, *Annales de Chimie*, Juillet, 1831.) *Pectic acid* thus obtained is in the form of a colourless jelly, slightly acidulous, with the property of reddening litmus paper, scarcely soluble in cold water, more soluble in boiling water, and forming with the latter a solution, which, though it does not become solid on cooling, is coagulated by the addition of alcohol, lime-water, acids, or salts, and even of sugar if allowed to stand for some time. With the alkalies the acid forms salts which are also capable of assuming the consistence of a jelly. With the earths and metallic oxides it forms insoluble salts. Braconnot thinks that pectic acid exists in many plants already formed, being produced by the reaction of alkalies present in the plant upon the pectin. The views of Braconnot have been confirmed by M. Fremy, who also found that pectin results, in fruits, from the reaction of acids upon a peculiar insoluble substance they contain when immature; and that pectin is changed into pectic acid not only by alkalies, but also by vegetable albumen.

Medical Properties and Uses. The wild root possesses the same properties with the seeds, and may be used for the same purposes. That of the garden plant has acquired much reputation as an external application to phagedenic, sloughing, and cancerous ulcers, the fetor of which it is supposed to correct, while it sometimes changes the character of the diseased action. It is brought to the proper consistence by scraping. In this state it retains a portion of the active principles of the plant, which render it somewhat stimulant. Boiled and mashed, as usually recommended, the root is perfectly mild, and fit only to form emollient cataplasms.

Gen. Char. *Receptacle* paleaceous, setose. *Calyx* ovate, imbricated, with scales ovate, leafy at the end. *Seed-down* paleaceous, hairy, or none. *Willd.*

Carthamus tinctorius. Willd. *Sp. Plant.* iii. 1706. The *dyers' saffron* or *safflower* is an annual plant, with a smooth erect stem, somewhat branched at top, and a foot or two in height. The leaves are alternate, sessile, ovate, acute, entire, and furnished with spiny teeth. The flowers are compound, in large, terminal, solitary heads. The florets are of an orange-red colour, with a funnel-shaped corolla, of which the tube is long, slender, and cylindrical, and the border divided into five equal, lanceolate, narrow segments.

The plant is a native of the Levant and Egypt, but is cultivated in various parts of Europe and America. The florets are the part employed. They are brought to us chiefly from the ports of the Mediterranean. Considerable quantities are produced in this country, and sold under the name of American saffron.

Safflower in mass is of a red colour, diversified by the yellowness of the filaments contained within the floret. It has a peculiar slightly aromatic odour, and a scarcely perceptible bitterness. Among its ingredients are two colouring substances—one red, insoluble in water, slightly soluble in

alcohol, very soluble in alkaline liquids, and called *carthamite* (*carthamic acid* of Döbereiner); the other yellow and soluble in water. It is the former which renders safflower useful as a dye-stuff. Carthamite mixed with finely powdered talc forms the cosmetic powder known by the name of *rouge*.

These flowers are sometimes fraudulently mixed with saffron, which they resemble in colour, but from which they may be readily distinguished by their tubular form, and by the yellowish style and filaments which they enclose.

Medical Properties. In large doses carthamus is said to be laxative; and administered in the state of warm infusion it proves somewhat diaphoretic. It is used in domestic practice, as a substitute for saffron, in measles, scarlatina, and other exanthematous diseases, in order to promote the eruption. An infusion made in the proportion of two drachms to a pint of boiling water is usually employed, and given without restriction as to quantity.

Gen. Ch. Fruit ovate-oblong, striated. *Involucre* one-leafed. *Petals* keeled, inflexed-emarginate. *Willd.*

Carum Carui. Willd. *Sp. Plant.* i. 1470; Woodv. *Med. Bot.* p. 102. t. 41. This plant is biennial and umbelliferous, with a spindle-shaped, fleshy, whitish root, and an erect stem, about two feet in height, branching above, and furnished with doubly pinnate, deeply incised leaves, the segments of which are linear and pointed. The flowers are small and white, and terminate the branches of the stem in erect umbels, which are accompanied with an involucre consisting sometimes of three or four leaflets, sometimes of one only, and are destitute of partial involucre.

The caraway plant is a native of Europe, growing wild in meadows and pastures, and cultivated in many places. It has been introduced into this country. The flowers appear in May and June, and the seeds, which are not perfected till the second year, ripen in August. The root, when improved by culture, resembles the parsnip, and is used as food by the inhabitants of the North of Europe. The seeds are the part used in medicine. They are collected by cutting down the plant and threshing it on a cloth. Our markets are supplied partly from Europe, partly from our own gardens. The American seeds are usually rather smaller than those brought from Germany.

Caraway seeds (half-fruits) are about two lines in length, slightly curved, with five longitudinal ridges which are of a light yellowish colour, while the intervening spaces are dark brown. They have a pleasant aromatic smell, and a sweetish, warm, spicy taste. These properties depend on an essential oil, which they afford largely by distillation. The residue is insipid. They yield their virtues readily to alcohol, and more slowly to water.

Medical Properties and Uses. Caraway is a pleasant stomachic and carminative, occasionally used in flatulent colic, and as an adjuvant or cor-

rective of other medicines. The dose in substance is from a scruple to a drachm. An infusion may be prepared by adding two drachms of the seeds to a pint of boiling water. The volatile oil, however, is most employed. (See *Oleum Cari*.) The seeds are sometimes baked in cakes, to which they communicate an agreeable flavour, while they serve to stimulate the digestive organs.

This small tree is one of the most elegant of those which inhabit the sunny clime of India. It has a pyramidal form, is always green, and is adorned throughout the year with a succession of beautiful rosy flowers. The stem is of hard wood, and covered with a smooth grayish bark. The leaves are about four inches in length by two in breadth, obovate-oblong, acuminate at both ends, entire, sinuated, with many parallel veins on each side of the midrib, supported upon long footstalks, and opposite to each other upon the branches. They have a firm consistence, a shining green colour, and when bruised are highly fragrant. The flowers are disposed in terminal corymbose panicles, and exhale a strong, penetrating, and grateful odour.

The natural geographical range of the clove-tree is extremely limited. It was formerly confined to the Molucca islands, in most of which it grew abundantly before their conquest by the Dutch. By the monopolizing policy of this commercial people, the trees were extirpated in nearly all the islands except Amboyna and Ternate, which were under their immediate inspection. Notwithstanding, however, the jealous vigilance of the Dutch, a French governor of the Isle of France and of Bourbon, named Poivre, succeeded, in the year 1770, in obtaining plants from the Moluccas, and introducing them into the colonies under his control. Five years afterwards, the clove-tree was introduced into Cayenne and the West Indies, in 1803

into the Island of Sumatra, and in 1818 into Zanzibar. It is now cultivated largely in these and other places; and commerce has ceased to depend on the Moluccas for supplies of this valuable spice.

The unexpanded flower buds are the part of the plant employed under the ordinary name of cloves.* They are first gathered when the tree is about six years old. The fruit has similar aromatic properties, but much weaker. The buds are picked by the hand, or separated from the tree by long reeds, and are then quickly dried. In the Moluccas they are said to be sometimes immersed in boiling water, and afterwards exposed to smoke and artificial heat, before being spread out in the sun. In Cayenne and the West Indies they are dried simply by the solar heat.

Cloves appear to have been unknown to the ancients. They were first introduced into Europe by the Arabians, and were circulated through the medium of Venetian commerce. After the discovery of the southern passage to India, the trade in this spice passed into the hands of the Portuguese; but it was subsequently wrested from them by the Dutch, by whom it was long monopolized. Within a few years, however, the extended culture of the plant has opened new sources of supply; and the commerce in cloves is no longer restricted to a single nation. The United States derive their chief supplies from the West Indies and the European colonies in Guiana. Of the average annual import, according to the custom-house returns, from 1820 to 1828 inclusive, 43,240 pounds were brought from the West Indies or South America, and 12,828 from France; while from England, Holland, and the East Indies together, the amount imported was only 11,090 pounds; and as the cloves obtained from France were probably of American growth, it appears that we can receive but a very small proportion of those produced in the Moluccas. The latter are said to be thicker, darker, heavier, more oily, and more highly aromatic than those of the colonies to which the clove-tree has been transplanted. They are known in commerce by the name of *Amboyna cloves*. Those of *Bencoolen*, from Sumatra, are deemed equal if not superior by the English druggists.

Properties. Cloves resemble a nail in shape, are usually rather more than half an inch long, and have a round head with four spreading points beneath it. Their colour is externally deep brown, internally reddish; their odour strong and fragrant; their taste hot, pungent, aromatic, and very permanent. The best cloves are large, heavy, brittle, and exude a small quantity of oil on being pressed or scraped with the nail. When light, soft, wrinkled, pale, and of feeble taste and smell, they are inferior. We are told that those from which the essential oil has been distilled are sometimes fraudulently mixed with the genuine.

Trommsdorff obtained from 1000 parts of cloves 180 of volatile oil, 170 of a peculiar tannin, 130 of gum, 60 of resin, 280 of vegetable fibre, and 180 of water. M. Lodibert afterwards discovered a fixed oil, aromatic and of a green colour, and a white resinous substance which crystallizes in fasciculi composed of very fine diverging silky needles, without taste or smell, soluble in ether and boiling alcohol, and exhibiting no alkaline reaction. This substance, called by M. Bonastre *caryophyllin*, was found in the cloves of the Moluccas, of Bourbon, and of Barbadoes, but not in those of Cayenne. Berzelius considers it a stearoptene, and probably identical with that deposited by the oil of cloves when long kept. M. Dumas has discovered another crystalline principle, which forms in the water distilled from cloves,

* The peduncles of the flowers have been sometimes employed. They possess the odour and taste of the cloves, though in a less degree, and furnish a considerable quantity of essential oil. The French call them *griffes de giroflès*.

and is gradually deposited. Like caryophyllin, it is soluble in alcohol and ether, but differs from that substance in assuming a red colour when touched with nitric acid. M. Bonastre proposes for it the name of *eugenin*. (*Journ. de Pharm.* xx. 565). Water extracts the odour of cloves with comparatively little of their taste. All their sensible properties are imparted to alcohol, and the tincture when evaporated leaves an excessively fiery extract, which becomes insipid when deprived of the oil by distillation with water, while the oil which comes over is mild. Hence it has been inferred that the pungency of this aromatic depends on a union of the essential oil with the resin. For an account of the oil of cloves, see *Oleum Caryophylli*. The infusion and oil of cloves are reddened by nitric acid, and rendered blue by tincture of chloride of iron; facts of some interest, as morphia affords the same results with these reagents.

Medical Properties and Uses. Cloves are among the most stimulant of the aromatics, but, like others of this class, exert less effect upon the system at large than on the part to which they are immediately applied. They are sometimes administered in substance or infusion to relieve nausea and vomiting, correct flatulence, and excite languid digestion; but their chief use is to assist or modify the action of other medicines. They enter as ingredients into several official preparations. Their dose in substance is from five to ten grains.

The French Codex directs a *tincture of cloves* to be prepared by digesting for six days, and afterwards filtering, a mixture of four ounces of powdered cloves and sixteen of alcohol of 31° Cartier. Three ounces to the pint of alcohol is a sufficiently near approximation.

CASCARILLA. *U. S., Lond., Ed., Dub.*

Cascarilla.

“The bark of Croton Eleutheria.” *U. S.* “Croton Cascarilla. (*Don.*) *Cortex.*” *Lond.* “Bark probably of Croton Eleuteria, and possibly other species of the same genus.” *Ed.* “Croton Cascarilla. *Cortex.*” *Dub.*

Cascarille, *Fr.*; Cascarillrinde, *Ger.*; Cascariglia, *Ital.*; Chacarila, *Span.*

CROTON. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Euphorbiaceæ.

Gen. Ch. MALE. *Calyx* cylindrical, five-toothed. *Corolla* five-petalled. *Stamens* ten to fifteen. FEMALE. *Calyx* many-leaved. *Corolla* none. *Styles* three, bifid. *Capsule* three-celled. *Seed* one. *Willd.*

Cascarilla has been ascribed by different authors to different species of Croton. The United States and Edinburgh Pharmacopœias indicate the *C. Eleutheria*, that of the Dublin College, the *C. Cascarilla* of Linnæus. Both species grow in the West Indies, and it is not impossible that the bark of both has been sold as cascarilla; but there is reason to believe that the *C. Eleutheria* is at least the most abundant source of it. The London College is undoubtedly wrong in ascribing it to the *C. Cascarilla* of Don. This botanist mistook the *Copalchi* bark of Mexico, which is produced by the *Croton Pseudo-China* of Schiede, and bears some resemblance to cascarilla, for the genuine bark, and hence proposed to transfer the specific name of

Cascarilla to the Mexican plant;—an unfortunate error, to which the London College has given authority by its sanction. No fact is better ascertained than that the proper cascarilla bark is a West India product, and is never brought from Mexico. The Copalchi bark has sometimes been mistaken also for a variety of cinchona, to which, however, it bears no great resemblance.

Croton Eleutheria. Willd. *Sp. Plant.* iv. 545; Sloane's Jamaica, vol. ii. t. 174. This species of Croton is a small tree or shrub, said by Browne to be four or five feet in height, but as seen by Dr. Wright in Jamaica, rising to twenty feet, and branching thickly towards the summit. The leaves are entire, ovate or cordate lanceolate, and elongated towards the apex, which is blunt. They are of a bright green colour upon their upper surface, and stand alternately upon short footstalks. The flowers, which are of a whitish colour, are disposed in axillary and terminal racemes. This shrub grows wild in the West Indies, especially the Bahama islands, in one of which—the small island of Eleutheria—it is found so abundantly as to have received its name from that circumstance. It is called by Browne *sea-side balsam*.

Croton Cascarilla. Willd. *Sp. Plant.* iv. 531; Woodv. *Med. Bot.* p. 629. t. 222. This is still smaller than the preceding species, and is called by Browne the *small sea-side balsam*. The stem is branched and covered with brown bark, of which the external coat is rough and whitish. The leaves are long, very narrow, somewhat pointed, entire, of a bright green colour on the upper surface, downy and of a silvery whiteness on the under. They are placed alternately on short foot-stalks. The flowers are small, greenish, and disposed in long terminal spikes. This plant is a native of the Bahamas, has been found abundantly in Hayti, and is said also to grow in Peru and Paraguay. Browne describes it as hot and pungent to the taste. The *Croton lineare* of Jacquin, considered by Willdenow as a variety of the *C. Cascarilla*, is made a distinct species by Sprengel. It is the wild rosemary of Jamaica, and is said by Dr. Wright to have none of the sensible qualities of cascarilla.

Cascarilla is brought to this market from the West Indies, and chiefly, as we have been informed, from the Bahamas. It comes in bags or casks. We have observed it in the shops in two forms so distinct as almost to deserve the title of varieties. In one, the bark is in rolled pieces of every size from three or four inches in length and half an inch in diameter to the smallest fragments, covered externally with a dull whitish or grayish-white epidermis, which in many portions is partially, sometimes wholly removed, leaving a dark-brown surface, while the inner surface has a chocolate colour, and the fracture is reddish-brown. The small pieces are sometimes curled, but have a distinct abrupt edge as if broken from the branches. The second variety consists entirely of very small pieces not more than an inch or two in length, very thin, without the white epidermis, not regularly quilled, but curved more or less in the direction of their length, often having a small portion of woody fibre attached to their inner surface, and presenting an appearance precisely as if shaved by a knife from the stem or branches of the shrub. Whether these two varieties are derived from distinct species, or differ only from the mode of collection, or the part of the plant from which they are taken, it is difficult to determine.

Properties. Cascarilla has an aromatic odour, rendered much more distinct by friction, and a warm, spicy, bitter taste. It is brittle, breaking with a short fracture. When burnt it emits a pleasant odour very closely resembling that of musk, but weaker and more agreeable. This property serves to distinguish it from all other barks. Trommsdorff found it to contain 1·6

of a greenish-yellow volatile oil, having a penetrating odour analogous to that of the bark, and the sp. gr. 0·938, 15·1 of a brown, soft, slightly bitter resin, 18·7 of bitter extractive mixed with gum and traces of chloride of potassium, and 65·6 of lignin. (Berzelius, *Traité de Chim.*) Either alcohol or water will partially extract its active matters; but diluted alcohol is the proper menstruum.

Medical Properties and Uses. This bark is aromatic and tonic. It was known in Germany so early as the year 1690, and was much used as a substitute for Peruvian bark by those who were prejudiced against this febrifuge in the treatment of remittent and intermittent fevers. It has, however, lost much of its reputation, and is now employed only where a pleasant and gently stimulant tonic is desirable; as in dyspepsia, chronic diarrhœa and dysentery, flatulent colic, and other cases of debility of the stomach or bowels. It is sometimes advantageously combined with the more powerful bitters. It may be given in powder or infusion. The dose of the former is from a scruple to half a drachm, which may be repeated several times a day. In consequence of its pleasant odour when burnt, some smokers mix it in small quantity with their tobacco; but it is said when thus employed to occasion vertigo and intoxication.

CASSIA. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Fabaceæ or Leguminosæ.

Gen. Ch. Calyx five-leaved. Petals five. Anthers, three upper sterile, three lower beaked. Lomentum. Willd.

The tree which yields the purging cassia is ranked by many botanists in a distinct genus, separated from the *Cassia* and denominated *Cathartocarpus*, of which the following is given as the essential generic character. “Calyx five-parted, deciduous. Corolla regular, of five petals. The lower filaments bowed. Pods long, woody, many-celled. Cells filled with pulp.” Lindley, in *Loud. Encyc. of Plants*.

Cassia Fistula. Willd. *Sp. Plant.* ii. 518; Woodv. *Med. Bot.* p. 445. t. 160.—*Cathartocarpus Fistula*. Persoon, *Synops.* i. 459. This is a large tree, rising to the height of forty or fifty feet, with a trunk of hard heavy wood, dividing towards the top into numerous spreading branches, and covered with a smooth ash-coloured bark. The leaves are commonly composed of five or six pairs of opposite leaflets, which are ovate, pointed, undulated, smooth, of a pale green colour, from three to five inches long, and supported upon short petioles. The flowers are large, of a golden yellow colour, and arranged in long pendent axillary racemes. The fruit consists of long, cylindrical, woody, dark-brown, pendulous pods, which, when agitated by the wind, strike against each other, and produce a sound that may be heard at a considerable distance.

This species of *Cassia* is a native of Upper Egypt and India, whence it is

generally supposed to have been transplanted to other parts of the world. It is at present very extensively diffused through the tropical regions of the old and new continents, being found in Insular and Continental India, Cochin China, Egypt, Nubia, the West Indies, and the warmer parts of America. The fruit is the officinal portion of the plant. It is imported from the East and West Indies, chiefly the latter, and from South America.

Properties. Cassia pods are a foot or more in length, straight or but slightly curved, cylindrical, less than an inch in diameter, with a woody shell, externally of a dark brown colour, and marked with three longitudinal shining bands, extending from one end to the other, two of which are in close proximity, appearing to constitute a single band, and the third is on the opposite side of the pod. These bands mark the place of junction of the valves of the legume, and are represented as sometimes excavated in the form of furrows. There are also circular depressions at unequal distances. Internally the pod is divided into numerous cells by thin transverse plates, which are covered with a soft, black pulp. Each cell contains a single, oval, shining seed. The pods brought from the East Indies are smaller, smoother, have a blacker pulp, and are more highly esteemed than those which come from the West Indies. We have seen a quantity of pods in this market, sold as cassia pods, which were an inch and a half in diameter, flattened on the sides, exceedingly rough on the outer surface, and marked by three longitudinal very elevated ridges, corresponding to the bands or furrows of the common cassia. The pulp was rather nauseous, but answered all the purposes required of the medicine. They corresponded exactly with a specimen of the fruit of the *Cassia Brasiliana* brought from the West Indies, and were probably derived from that plant.

The heaviest pods, and those which do not make a rattling noise when shaken, are to be preferred, as they contain a larger portion of the pulp, which is the part employed. This should be black and shining, and have a sweet taste. It is apt to become sour if long exposed to the air, or mouldy if kept in a damp place. The pulp is extracted from the pods by first bruising them, then boiling them in water, and afterwards evaporating the decoction; or, when the pods are fresh, by opening them at the sutures, and removing the pulp by a spatula. (*See Cassiæ Fistulæ Pulpa.*)

The pulp is the portion considered officinal by the British Colleges; but as it is the pod that is usually kept in the shops, the United States Pharmacopœia designates the latter. Cassia pulp has a slight rather sickly odour, and a sweet mucilaginous taste. From the analysis of M. Henry it appears to contain sugar, gum, a substance analogous to tannin, a colouring matter soluble in ether, traces of a principle resembling gluten, and a small quantity of water.

Medical Properties and Uses. Cassia pulp is gently laxative, and may be advantageously given in small doses in cases of habitual costiveness. In quantities sufficient to purge, it occasions nausea, flatulence, and griping. In this country it is very rarely prescribed, except as an ingredient in the confection of senna, which is a highly pleasant and useful laxative preparation. The dose of the pulp as a laxative is one or two drachms, as a purge one or two ounces.

CASSIA MARILANDICA. U. S.

American Senna.

"The leaves of Cassia Marilandica." U. S.

CASSIA. See CASSIA FISTULA.

Cassia Marilandica. Willd. *Sp. Plant.* ii. 524; Bigelow *Am. Med. Bot.* ii. 116; Barton, *Med. Bot.* i. 137. This is an indigenous perennial plant, of vigorous growth, sending up annually numerous round, erect, nearly smooth stems, which are usually simple, and rise from three to six feet in height. The leaves are alternate, and composed of from eight to ten pairs of oblong lanceolate, smooth, mucronate leaflets, green on their upper surface, pale beneath, and connected by short petioles with the common footstalk, which is compressed, channeled above, and furnished near its base with an ovate, stipitate gland. The flowers, which are of a beautiful golden yellow colour, grow in short axillary racemes at the upper part of the stem. The calyx is composed of five oval, obtuse, unequal, yellow leaves; the corolla of the same number of spatulate, concave petals, of which three are ascending, and two descending and larger than the others. The stamens are ten, with yellow filaments and brown anthers, which open by a terminal pore. The three upper stamens bear short abortive anthers; the three lowermost are long, curved, and tapering into a beak. The germ, which descends with the latter, bears an erect style terminating in a hairy stigma. The fruit is a pendulous legume, from two to four inches long, linear, curved, swelling at the seeds, somewhat hairy, and of a blackish colour.

The *American senna*, or *wild senna* as it is sometimes called, is very common in all parts of the United States south of New York, and grows naturally as far northward as the southern boundary of Massachusetts. It prefers a low, moist, rich soil, in the vicinity of water, and, though frequently found in dryer and more elevated places, grows most abundantly and luxuriantly in the flat ground on the borders of rivers and ponds. It is sometimes cultivated to the northward in gardens for medical use. In the months of July or August, when it is in full bloom, it exhibits a rich and beautiful appearance. The leaves should be collected in August, or the beginning of September, and carefully dried.

They are sometimes brought into the market, compressed into oblong cakes, such as those prepared by the Shakers from most herbaceous medicinal plants. The leaflets are from an inch and a half to two inches long, from one quarter to half an inch in breadth, thin, pliable, and of a pale green colour. They have a feeble odour, and a nauseous taste somewhat analogous to that of senna. Water and alcohol extract their virtues. They were analyzed by Mr. Martin of Philadelphia, and found to contain a principle analogous to *cathartin* in chemical properties and effects on the system, albumen, mucilage, starch, chlorophylle, yellow colouring matter, volatile oil, fatty matter, resin, and lignin, besides salts of potassa and lime. (*Am. Journ. of Pharm.* i. 22.)

Medical Properties and Uses. American senna is an efficient and safe cathartic, closely resembling the imported senna in its action, and capable of being substituted for it in all cases in which the latter is employed. It is, however, less active; and to produce an equal effect must be administered in a dose about one-third larger. It is habitually used by many practitioners in the country. Like senna, it is most conveniently given in the form of infusion, and should be similarly combined in order to obviate its tendency to produce griping.

CASTANEA. U.S. Secondary.

Chinquapin.

“The bark of *Castanea pumila*.” U. S.

CASTANEA. *Sex. Syst.* Monœcia Polyandria.—*Nat. Ord.* Cupuliferae.

Castanea pumila. Willd. *Sp. Plant.* iv. 461; Michaux, *N. Am. Sylv.* iii. 15. The chinquapin is an indigenous shrub or small tree, which, in the Middle States, rarely much exceeds seven or eight feet in height; but in Carolina, Georgia, and Louisiana, sometimes attains an elevation of thirty or forty feet, with a diameter of trunk equal to twelve or fifteen inches. The leaves are oblong, acute, mucronately serrate, and distinguished from those of the chestnut, which belongs to the same genus, by their whitish and downy under surface. The barren flowers are grouped upon axillary peduncles three or four inches long, the fertile aments are similarly disposed but less conspicuous. The fruit is spherical, covered with sharp prickles, and encloses a brown nut which is sweet and edible, but differs from the chestnut in being much smaller, and convex on both sides.

The tree extends from the banks of the Delaware, southward to the Gulf of Mexico, and south-westward to the Mississippi. It is most abundant in the southern portion of this tract of country. The bark is the part used. It is astringent and tonic, and has been employed in the cure of intermittents; but has no peculiar virtues to recommend it, and might well be spared even from the Secondary Catalogue of the Pharmacopœia. W.

CASTOREUM. U.S., Lond., Ed., Dub.

Castor.

“A peculiar concrete substance obtained from *Castor fiber*.” U. S. “*Castor fiber. Concretum in folliculis præputii repertum.*” Lond. “A peculiar secretion in the præputial follicles of *Castor fiber*.” Ed.

Castoreum, *Fr.*; Bibergeil, *Germ.*; Castoro, *Ital.*; Castoreo, *Span.*

In the beaver, *Castor fiber* of naturalists, between the anus and external genitals of both sexes, are two pairs of membranous follicles, of which the lower and larger are pear-shaped, and contain an oily, viscid, highly odorous substance, secreted by glands which lie externally to the sac. This substance is called castor. After the death of the animal, the follicles containing it are removed and dried either by smoke or in the sun; and in this state are brought into the market.

This drug is derived either from the northern and north-western parts of the American continent, or from the Russian dominions; and is distinguished, according to its source, into the Canadian or American, and Russian castor. Of the latter but a very small portion reaches this country. That which is brought to Philadelphia is derived chiefly from Missouri.

Castor comes to us in the form of solid unctuous masses, contained in sacs about two inches in length, larger at one end than at the other, much flattened and wrinkled, of a brown or blackish colour externally, and united in pairs by the excretory ducts which connect them in the living animal.

In each pair, one sac is generally larger than the other. They are divided internally into numerous cells containing the castor, which, when the sacs are cut or torn open, is exhibited of a brown or reddish-brown colour intermingled more or less with the whitish membrane forming the cells. Those brought from Russia are larger, fuller, heavier, and less tenacious than the American; and their contents, which are of a rusty or liver-colour, have a stronger taste and smell, and are considered more valuable as a medicine. A variety of Russian castor, described by Pereira under the name of *chalky Russian castor*, is in smaller and rounder sacs than the American, has a peculiar empyreumatic odour very different from that of the other varieties, breaks like starch under the teeth, and is characterized by effervescing with dilute muriatic acid. In the castor from Missouri, the contents of the sac are sometimes almost white, and evidently of inferior quality. It is said by M. Kohli, that the Canadian castor, treated with distilled water and ammonia, affords an orange precipitate, while the matter thrown down from the Russian under similar treatment is white.

Properties. Good castor has a strong, fetid, peculiar odour; a bitter, acrid, and nauseous taste; and a colour more or less tinged with red. It is of a softer or harder consistence according as it is more or less thoroughly dried. When perfectly desiccated, though still somewhat unctuous to the touch, it is hard, brittle, and of a resinous fracture. Its chemical constituents, according to Brandes, whose analysis is the most recent, are volatile oil; a resinous matter; albumen; a substance resembling osmazome; mucus; urate, carbonate, benzoate, phosphate, and sulphate of lime; acetate and muriate of soda; muriate, sulphate, and benzoate of potassa; carbonate of ammonia; membranous matter; and a peculiar proximate principle previously discovered by M. Bizio, an Italian chemist, and called by him *castorin*. This principle crystallizes in long, diaphanous, fasciculated prisms, has the smell of castor, of which it is alleged to be the active constituent, and a taste like that of copper. It is insoluble in cold water and in cold alcohol; but is dissolved by one hundred parts of the latter liquid at the boiling temperature, and by the essential oils. It possesses neither alkaline nor acid properties. It may be obtained by treating castor minutely divided with six times its weight of boiling alcohol, filtering the liquor while hot, and allowing it to cool. The *castorin* is slowly deposited, and may be purified by the action of cold alcohol. Its claim to be considered the active principle of castor is very doubtful.

Alcohol and sulphuric ether extract the virtues of castor. An infusion made with boiling water has its sensible properties in a slight degree; but the odorous principle of the drug is dissipated by decoction.

The virtues of castor are impaired by age; and the change is more rapid in proportion to the elevation of temperature. Moisture promotes its speedy decomposition. In a dry cool place it may be kept for a long time without material deterioration. When quite black, with little taste or smell, it is unfit for use. A factitious preparation is sometimes sold, consisting of a mixture of various drugs, scented with genuine castor, intermingled with membrane, and stuffed into the scrotum of a goat. The fraud may be detected by the comparatively feeble odour, the absence of other characteristic sensible properties, and the want of the smaller follicles containing fatty matter, which are always attached to the real bags of castor.

Medical Properties and Uses. Castor is moderately stimulant and antispasmodic. The experiments of Thouvenel prove, that in large doses it quickens the pulse, increases the heat of the skin, and produces other symptoms of general excitement; but its force is chiefly directed to the nervous

system, and in small doses it scarcely disturbs the circulation. It has also enjoyed a high reputation as an emmenagogue. It was employed by the ancients. Pliny and Dioscorides speak of it as useful in hysteria and amenorrhœa. In Europe, especially on the continent, it is still frequently prescribed in low forms of fever attended with nervous symptoms, in spasmodic diseases, such as hysteria and epilepsy, in many anomalous nervous affections, and in diseases dependent on or connected with suppression or retention of the menses. The practitioners of this country rarely resort to it. The dose in substance is from ten to twenty grains, which may be given in bolus, or emulsion. The tincture is sometimes employed.

NEPETA. *Sex. Syst.* Didynamia Gymnospermia.—*Nat. Ord.* Lamiaceæ or Labiatae.

Gen. Ch. *Calyx* dry, striate, five-toothed. *Corolla* with the upper lip undivided, the under lip three-parted, the middle division crenate. *Stamens* approximate.

Nepeta Cataria. The *Catnep* or *Catmint* is a perennial, herbaceous plant, with a quadrangular, branching, somewhat hoary stem, from one to three feet high, and furnished with opposite, petiolate, cordate, dentate, pubescent leaves, which are green above and whitish on their under surface. The flowers are whitish or slightly purple, are arranged in whorled spikes, and appear in July and August. The plant is abundant in the United States, but is supposed to have been introduced from Europe.

The whole herbaceous part of the plant is used; but the leaves only are recognised in the United States Pharmacopœia. They have a strong, peculiar, rather disagreeable odour, and a pungent, aromatic, bitterish, camphorous taste. They yield their virtues to water. The active constituents are volatile oil, and tannin of the variety which produces a greenish colour with the salts of iron.

In its operation upon the system, catnep is tonic and excitant, bearing considerable resemblance to the mints and other labiate plants. It has had the reputation also of being antispasmodic, and emmenagogue. Cats are said to be very fond of it, and it has been asserted to act as an aphrodisiac in these animals. It is employed as a domestic remedy, in the form of infusion, in amenorrhœa, chlorosis, hysteria, the flatulent colic of infants, &c.; but is scarcely known in regular practice. Some of the older writers speak favourably of its powers. Two drachms of the dried leaves or herb may be given as a dose in infusion. W.

ACACIA. See ACACIA.

Acacia Catechu. Willd. *Sp. Plant.* iv. 1079; Woodv. *Med. Bot.* p. 433. t. 157. According to Mr. Kerr, whose description has been followed by most subsequent writers, the *Acacia Catechu* is a small tree, seldom more than twelve feet in height, with a trunk one foot in diameter, dividing towards the top into many close branches, and covered with a thick, rough, brown bark. The leaves, which stand alternately upon the younger branches, are composed of from fifteen to thirty pairs of pinnæ nearly two inches long, each of which is furnished with about forty pairs of linear leaflets, beset with short hairs. At the base of each pair of pinnæ is a small gland upon the common foot-stalk. Two short, recurved spines are attached to the stem at the base of each leaf. The flowers are in close spikes, which arise from the axils of the leaves, and are about four or five inches long. The fruit is a lanceolate, compressed, smooth, brown pod, with an undulated thin margin, and contains six or eight roundish flattened seeds, which when chewed emit a nauseous odour.

This species of *Acacia* is a native of the East Indies, growing abundantly in various provinces of Hindostan, and in the Burman empire. Pereira says that it is now common in Jamaica. Like most others of the same genus, it abounds in astringent matter, which may be extracted by decoction. *Catechu* is an extract from the wood of the tree.

This drug had been long known in medicine before its true source was discovered. It was at first called *terra Japonica*, under the erroneous impression that it was an earthy substance derived from Japan. When ascertained by analysis to be of vegetable origin, it was generally considered by writers on the *Materia Medica* to be an extract obtained from the *betel-nut*, which is the fruit of a species of palm, denominated by Linnæus *Areca Catechu*. The true origin of the drug was made known by Mr. Kerr, assistant-surgeon of the civil hospital in Bengal, who had an opportunity not only of examining the tree from which it was obtained, but also of witnessing the process of its extraction. According to Mr. Kerr, the manufacturer, having carefully cut off the exterior white part of the wood, reduces the interior brown or reddish-coloured portion into chips, which he then boils in water in unglazed earthen vessels, till all the soluble matter is dissolved. The decoction thus obtained is evaporated first by artificial heat, and afterwards in the sun, till it has assumed a thick consistence, when it is spread out to dry upon a mat or cloth, being, while yet soft, divided by means of a string into square or quadrangular pieces. The account more recently given by Dr. Royle, of the preparation of the extract in Northern India, is essentially the same. The process, as he observed it, was completed by the pouring of the extract into quadrangular earthen moulds. Our own countryman, the Rev. Howard Malcolm, states in his "Travels in South Eastern Asia," that catechu is largely prepared from the wood of the *Acacia Catechu* in the vicinity of Prome, in Burmah. Two kinds, he observes, are prepared from the same tree, one *black*, which is preferred in China, and the other *red*, which is most esteemed in Bengal. According to some authors, the unripe fruit and leaves are also submitted to decoction, and Mr. Kerr states that the areca nut may sometimes be added to the other ingredients in places where it is abundant.

The name *catechu* in the native language signifies the *juice of a tree*, and

appears to have been applied to astringent extracts obtained from various plants. According to the United States, London, and Dublin Pharmacopœias, however, the term is properly restricted to the extract of the *Acacia Catechu*; as it was not intended to recognise all the astringent products which are floating in Asiatic commerce; and those from other sources than the *Acacia*, though they may occasionally find their way into our shops, do so as an exception to the general rule. A minute account of the diversified forms and exterior characters, which the official catechu presents as produced in different localities, would rather tend to perplex the reader than to serve any good practical purpose. These characters are, moreover, frequently changing, as the drug is procured from new sources, or as slight variations may occur in the mode of its preparation. Commerce is chiefly supplied with catechu from Bahar, Northern India, and Nepal through Calcutta, from Canara through Bombay, and from the Burman dominions. We derive it directly from Calcutta, or by orders from London, and it is sold in our markets without reference to its origin. It is frequently called *cutch* by the English traders, a name derived, no doubt, from the Hindoostanee word *cutt*.*

* In order not to embarrass the text unnecessarily, we have thrown together into the form of a note the following observations upon the varieties of catechu, those being first considered which are probably derived from the *Acacia Catechu*, and therefore entitled to an official rank.

1. *Official Catechus.*

The following, so far as we have been able to distinguish them, are the varieties of official catechu to be found in the markets of Philadelphia.

1. *Plano-convex Catechu. Cake Catechu.* This is in the form of circular cakes, flat on one side, convex on the other, and usually somewhat rounded at the edge, as if the soft extract had been placed in saucers, or vessels of a similar shape, to harden. As found in the retail shops it is almost always in fragments, most of which, however, exhibit some evidences of the original form. The cakes are of various size, from two or three to six inches or more in diameter, and weighing from a few ounces to nearly two pounds. Their exterior is usually smooth and dark brown, but we have seen a specimen in which the flat surface exhibited impressions as if produced by coarse matting. The colour internally is always brown, sometimes of a light yellowish-brown or chocolate colour, but more frequently dark reddish-brown, and sometimes almost black. The cakes are almost always more or less cellular in their interior; but in this respect great diversity exists. Sometimes they are very porous, so as almost to present a spongy appearance, sometimes compact and nearly uniform; and this difference may be observed even in the same piece. The fracture is sometimes rough and dull, but in the more compact parts is usually smooth and somewhat shining; and occasionally a piece split in one direction will exhibit a spongy fracture, while in another it will be shining and resinous, indicating the consolidation of the extract in layers. This variety of catechu is often of good quality. It is common at present in our market; but we have been unable to trace its origin accurately. There can be little doubt, from its internal character, that it comes from the East Indies, and is the product of *A. Catechu*; but no accounts that we have seen of the preparation of the drug in particular geographical sites, indicate this particular shape; and it is not impossible that portions of it may be formed out of other varieties of catechu by a new solution and evaporation.

2. *Pegu Catechu.* This is the product derived from the Burman dominions, and named from that section of the country whence it is exported. It enters commerce, probably in general through Calcutta, in large masses, sometimes of a hundred weight, consisting of layers of flat cakes, each wrapped in leaves said to be those of the *Nauclea Brunonis*. In this form, however, we do not see it in the shops; but almost always in angular irregular fragments, in which portions of two layers sometimes cohere with leaves between them, indicating their origin. It is characterized by its compactness, its shining fracture, and its blackish-brown or dark Port-wine colour, so that when finely broken it bears no inconsiderable resemblance to kino. This is an excellent variety of catechu, and is not unfrequent in the shops.

3. *Catechu in Quadrangular Cakes.* This is scarcely ever found in the shops in its complete form, and the fragments are often such that it would be impossible to infer from them the original shape of the cake. This is usually between two and three inches in

Properties. Catechu, as it comes to us, is in masses of different shapes, some in balls more or less flattened, some in circular cakes, some saucer-shaped, others cubical or oblong, or quite irregular, and of every grade in size, from small angular pieces, which are evidently fragments of the origi-

length and breadth, and somewhat less in thickness, of a rusty-brown colour externally, and dark brown or brownish-gray within, with a somewhat rough and dull fracture, but, when broken across the layers in which it is sometimes disposed, exhibiting a smoother and more shining surface. Guibourt speaks of the layers as being blackish externally and grayish within, and bearing some resemblance to the bark of a tree, a resemblance, however, which has not struck us in the specimens which have fallen under our notice. There is little doubt that this variety comes from the provinces of Bahar and Northern India, where the preparation of the drug was witnessed by Mr. Kerr and Dr. Royle, who both speak of it as being cut, when drying, into the quadrangular form. It has been called *Bengal Catechu*, because exported from that province.

4. *Catechu in Balls.* We have seen this in two forms—the one consisting of globular balls about as large as an orange, very hard and heavy, of a ferruginous aspect externally, very rough when broken, and so full of sand as to be gritty under the teeth; the other in cakes, originally, in all probability, globular, and of about the same dimensions, but flattened and otherwise pressed out of shape before being perfectly dried, sometimes adhering two together, as happens with the lumps of Smyrna opium, and closely resembling in external and internal colour, and in the character of their fracture, the quadrangular variety last described. The former kind is rare, and the specimens we have seen had been twenty years in the shop, and had very much the appearance of a factitious product. The latter is in all probability the kind known formerly as the *Bombay catechu*; as Dr. Hamilton, and more recently Major Mackintosh, in describing the mode of preparing catechu on the Malabar coast, of which Bombay is the entrepot, says that while the extract is soft it is shaped into balls about the size of an orange.

2. *Non-official Catechus.*

1. *Gambir. Terra Japonica.* An astringent extract is abundantly prepared in certain parts of the East Indies, under the name of *gambir* or *gambeer*, and imported into Europe and America under that of *terra Japonica*. The plant from which it is obtained, called by Mr. Hunter, who first minutely described it, *Nauclea Gambir*, but by Roxburgh, De Candolle and others, *Uncaria Gambir*, is a climbing shrub, belonging to the class and order *Pentandria Monogynia*, and to the natural order *Rubiaceæ* of Jussieu, *Cinchonaceæ* of Lindley. It is a native of Malacca, Sumatra, Cochin-china, and other parts of Eastern Asia, and is largely cultivated in the islands of Bintang, Singapore, and Prince of Wales. The gambir is prepared by boiling the leaves and young shoots in water, and evaporating the decoction either by artificial or solar heat. When of a proper consistence it is spread out into flat cakes in moulds or otherwise, and then cut into small cubes, which are dried in the sun.

Gambir is in the form of cubes, with sides about an inch square, is light and porous so that it floats when thrown in water, is of a deep yellowish or reddish-brown colour externally, but much paler within, presents a dull earthy surface when broken, is inodorous, and has a strongly astringent, bitter, and subsequently sweetish taste. It softens and swells up when heated, and leaves but a minute proportion of ashes when burnt. It is partially soluble in cold water, and almost wholly soluble in boiling water, which deposits a portion upon cooling. Nees von Eisenbeck found it to consist of from 36 to 40 per cent. of tannic acid, a peculiar matter, gum or gummy extractive, a deposit like the red cinchonic, and two and a half per cent. of lignin. (*Pereira*.) The peculiar principle is called *catechuin* or *catechuic acid*. This, when perfectly pure, is snow-white, of a silky appearance, crystallizable in fine needles, unalterable if dry in the air, fusible by heat, very slightly soluble in cold water with which it softens and swells up, soluble in boiling water which deposits it on cooling, and soluble also in alcohol and ether. It very slightly reddens litmus paper, and though it colours the solution of chloride of iron beautifully green, and produces with it a grayish-green precipitate, it differs from tannic acid in not affecting a solution of gelatin. It bears considerable analogy to gallic acid in its relations to the metallic salts. To prepare it, the precipitate which falls upon the cooling of the decoction of gambir, should be well washed upon a filter with cold water, and again dissolved in boiling water with a little purified animal charcoal. The solution being filtered, and allowed to stand, gradually deposits the acid, of a snow-white colour. To obtain it perfectly white in the dry state, it must be dried under an exhausted receiver with sulphuric acid. (*Wackenroder, Annal. der Pharm.* xxxi. 72.) The sweet taste of gambir is thought to depend on this constituent.

Several varieties of gambir are described. Sometimes it is in oblong instead of cubical

nal cakes, to lumps which weigh one or two pounds. The colour is externally of a rusty brown, more or less dark, internally varying from a pale reddish or yellowish-brown to a dark liver colour. In some specimens it is almost black, in others somewhat like the colour of Port-wine, and in others again, though rarely, dull red like annotta. The extract has been distinguished into the pale and dark varieties; but there does not appear to be sufficient ground for retaining this distinction. Catechu is inodorous, with an astrigent and bitter taste, which is followed by a sense of sweetness. It is brittle, and breaks with a fracture, which is rough in some specimens, in others uniform, resinous, and shining. That which is preferred in our market is of a dark colour, easily broken into small angular fragments, with a smooth glossy surface, bearing some resemblance to kino. Catechu is often mixed with sand, sticks, and other impurities. Its chief chemical constituents are tannin, extractive, and mucilage. Out of 200 parts of Bombay catechu, Sir H. Davy obtained 109 parts of tannin, 68 of extrac-

pieces, without differing in other respects from the ordinary kind; sometimes, in small circular cakes or short cylindrical pieces, heavier than water, of a pale reddish-yellow colour, moderately astrigent, gritty under the teeth, and quite impure; sometimes in very small cubes, distinguishable by the black colour they afford with tincture of iodine, indicating the admixture of sago or other amylaceous matter; and finally, in circular cakes of the size of a small lozenge, flat on one side, and somewhat convex on the other, of a pale pinkish yellowish-white colour, and a chalky feel. This is most highly esteemed by the natives in India. (Pereira.) None of these varieties occur to any extent in our commerce, and we have met with none of them in the shops.

Gambir was probably the substance first brought from the East under the name of *terra Japonica*. It is largely consumed in the East by the betel-chewers. Great quantities are imported into Europe, where it is used for tanning, calico printing, dyeing, &c. In this country it is also largely consumed by the calico printers. Though a strong astrigent, and applicable to the same purposes as the official catechu, it is seldom or never medicinally employed in this country. We have often seen it in the drug stores, but never in an apothecary's shop.

2. *Areca Catechu*. This is obtained from the *areca nut* or *betel nut*, which is the seed of the *Areca Catechu*, a palm cultivated in all parts of India. (See Appendix.) It is prepared by boiling the nuts in water and evaporating the decoction. There are two varieties, one of a black colour, very astrigent, mixed with paddy husks and other impurities, and obtained by evaporating the first decoction; the other, yellowish-brown, of an earthy fracture, and pure, resulting from the evaporation of a decoction of the nuts which had been submitted to the previous boiling. The first is called *kassu*, the other *coury*. (Heyne, *Tracts, &c. on India*.) They are prepared in Mysore, and Ainslie states that both varieties are sold in the bazars of Lower India, and used for the same purposes as the official catechu by the native and European practitioners. They are also much used for chewing by the natives. But they are seldom exported, and it is uncertain whether they find their way into European or American commerce. Pereira thinks he has identified the *kassu* with a variety of catechu derived from Ceylon, where he has been informed that an extract of the areca nut is prepared. It is in circular flat cakes, from two to three inches in diameter, scarcely an inch thick, covered on one side with paddy husks, and internally blackish-brown and shining, like Pegu catechu.

Guibourt and Pereira describe other varieties, which we have not met with, and which are probably rare. One of these is the *Siam Catechu*, in conical masses shaped like a betel nut, and weighing about a pound and a half. Its fracture is shining and liver-coloured, like that of hepatic aloes; in other respects it resembles Pegu catechu. (Pereira.) Another is the *black mucilaginous catechu* of Guibourt, in parallelipeds an inch and a half in length, by an inch in breadth. Internally it is black and shining, and its taste is mucilaginous and feebly astrigent. A third is the *dull reddish catechu* of Guibourt, in somewhat flattened balls, weighing three or four ounces, of a dull-reddish, wavy, and often marbled fracture. We saw something like this ten years since, which had been brought upon speculation by a gentleman from Calcutta, but is not now in the market. Lastly, there is a *pale* or *whitish* catechu, in small roundish or oval lumps, with an irregular surface, dark or blackish-brown externally, very pale and dull internally, and of a bitter astrigent and sweetish taste, with a smoky flavour. (Pereira.) It is unknown in commerce.

tive, 13 of mucilage, and 10 of insoluble residue. The same quantity of Bengal catechu yielded 97 of tannin, 73 of extractive, 16 of mucilage, and 14 of insoluble residue. The portion designated by Davy as extractive contains, if it do not chiefly consist of, a principle discovered by Buchner and now called *catechuic acid*. (See note page 194.) The *tannic acid* is of the variety which precipitates the salts of iron of a greenish-black colour. It precipitates gelatin, but not tartar-emetic. (*Kane*.) Catechu is almost entirely soluble in large quantities of water, to which it imparts a brown colour. Dr. Duncan states that 18 ounces at 52° are required to 100 grains of the extract, of which about $\frac{1}{4}$ of earthy matter is left undissolved. The extractive is much less soluble than the astringent principle, which may be almost entirely separated from it by the frequent application of small quantities of cold water. Boiling water dissolves the extractive matter much more readily than cold, and deposits it of a reddish-brown colour upon cooling. For the important chemical reactions of catechu see *Acidum Tannicum*.

Medical Properties and Uses. Catechu is gently tonic, and powerfully astringent. The dark coloured has the latter property in a somewhat greater degree than the light, and is therefore usually preferred. The latter, being rather sweeter, is preferred by the Malays, Hindoos, and other Indians, who consume vast quantities of this extract by chewing it, mixed with a small proportion of lime and with aromatics, and wrapped in the leaf of the *Piper Betel*. Catechu may be advantageously used in most cases where astringents are indicated, and, though less employed in this country than kino, is not inferior to it in medicinal virtues. The complaints to which it is best adapted are diarrhœa dependent on debility or relaxation of the intestinal exhalents, and passive hemorrhages, particularly that from the uterus. A small piece of it, held in the mouth and allowed slowly to dissolve, is an excellent remedy in relaxation of the uvula, and the irritation of the fauces and troublesome cough which depend upon it. Applied to spongy gums, in the state of powder, it sometimes proves useful; and it has been recommended as a dentifrice in combination with powdered charcoal, Peruvian bark, myrrh, &c. Sprinkled upon the surface of indolent ulcers, it is occasionally beneficial, and is much used in India for the same purpose mixed with other ingredients in the state of an ointment. An infusion or decoction of catechu may be used as an injection in obstinate gonorrhœa, gleet, and leucorrhœa; and we have found it highly beneficial, when thrown up the nostrils, in arresting epistaxis.

The dose is from ten grains to half a drachm, which should be frequently repeated, and is best given with sugar, gum Arabic, and water.

Gen. Ch. Receptacle bristly. Seed-down simple. Corollas of the ray funnelshaped, longer, irregular. *Willd.*

Centaurea benedicta. *Willd. Sp. Plant.* iii. 2315; *Woodv. Med. Bot.* p.

34. t. 14.—*Cnicus benedictus*. De Cand. *Prodrom*. vi. 606. The blessed thistle (*carduus benedictus*) is an annual herbaceous plant, the stem of which is about two feet high, branching towards the top, and furnished with long, elliptical, rough leaves, irregularly toothed, barbed with sharp points at their edges, of a bright green colour on their upper surface, and whitish on the under. The lower leaves are deeply sinuated, and stand on foot-stalks, the upper are sessile, and in some measure decurrent. The flowers are yellow, and surrounded by an involucre of ten leaves, of which the five exterior are largest. The calyx is oval, woolly, and composed of several imbricated scales, terminated by rigid, pinnate, spinous points.

This plant is a native of the South of Europe, and is cultivated in gardens in other parts of the world. It has become naturalized in the United States. The period of flowering is June, when its medicinal virtues are in greatest perfection. The leaves are the officinal portion. They should be gathered when the plant is in flower, quickly dried, and kept in a dry place.

The herb has a feeble unpleasant odour, and an intensely bitter taste, more disagreeable in the fresh than the dried plant. Water and alcohol extract its virtues. The infusion formed with cold water is a grateful bitter; the decoction is nauseous, and offensive to the stomach. The bitterness remains in the extract. The active constituents are volatile oil and a peculiar bitter principle, for which the name of *cnicin* has been proposed.

Medical Properties and Uses. The blessed thistle may be so administered as to prove tonic, diaphoretic, or emetic. The cold infusion, made with half an ounce of the leaves to a pint of water, has been employed as a mild tonic in debilitated conditions of the stomach. A stronger infusion, taken warm while the patient is confined to bed, produces copious perspiration. A still stronger infusion, or the decoction, taken in large draughts, provokes vomiting, and has been used to assist the operation of emetics. The herb, however, is at present little employed, as all its beneficial effects may be obtained from chamomile. The dose of the powder as a tonic is from a scruple to a drachm, that of the infusion two fluidounces. W.

ERYTHRÆA. Sex. Syst. Pentandria Monogynia.—*Nat. Ord.* Gentianaceæ.

Gen. Ch. Capsule linear. Calyx five-cleft. Corolla funnelshaped, with a short limb withering. Anthers often bursting, spiral. Stigmas two. *Loudon's Encyc.*

Erythræa Centaurium. Loudon's *Encyc. of Plants*, p. 130.—*Chironia Centaurium.* Willd. *Sp. Plant.* i. 1068; Woodv. *Med. Bot.* p. 275. t. 96. This is a small, annual, herbaceous plant, rising about a foot in height, with a branching stem, which divides above into a dichotomous panicle, and bears opposite, sessile, ovate lanceolate, smooth, and obtusely pointed leaves. The flowers are of a beautiful rose colour, standing without peduncles in the axils of the stems, with their calyx about half as long as the tube of the corolla. The plant grows wild in most of the countries of Europe, adorning the woods and pastures, during the latter part of summer, with its pretty and delicate flowers.

The herb, though without odour, has a strong bitter taste, which it imparts to water and alcohol. The flowering summits are generally preferred, though the Dublin College directs the leaves. The name of *centaurin* has been proposed for its bitter principle.

Medical Properties and Uses. The common centaury of Europe has tonic properties very closely resembling those of gentian, with which it is associated in the same natural family. It is employed on the other side of the Atlantic in dyspeptic complaints, and formerly had considerable reputation in the treatment of fever. It was one of the ingredients of the Portland powder. In the United States it has been superseded by the *Sabbatia angularis* or American Centaury. The dose of the powder is from thirty grains to a drachm. Another species of *Erythræa* (*E. Chilensis*) possesses similar properties, and is employed to a considerable extent in Chili as a mild tonic. W.

Off. Syn. CERA. *Apis mellifica*. *Concretum ab ape paratum*. Lond.

Cire jaune, Fr.; Gelbes Wachs, Germ.; Cera gialla, Ital.; Cera amarilla, Span.

Wax is one of the products of the common bee, *Apis mellifica* of naturalists, which constructs with it the cells of the comb in which the honey and larvæ are deposited. It was at one time a doubtful point, whether the insect elaborated its wax by its own organs, or merely gathered it already formed from vegetables. The question was set at rest by Huber, who fed a swarm of bees exclusively on honey and water, and found nevertheless that they formed a comb consisting of wax. This, therefore, is a proper secretion of the insect. It is produced in the form of scales under the rings of the belly. But wax also exists in plants, bearing in this, as in other respects, a close analogy to the fixed oils, which are found in both kingdoms, with almost as little discoverable difference as between animal and vegetable wax. It is, however, the product of the bee only that is recognised as officinal by the Pharmacopœias. This is directed in two forms: 1. that of *yellow wax* procured immediately from the comb; and 2. that of *white wax* prepared by depriving the former of its colour. We shall consider these separately, and afterwards give a brief account of *vegetable wax*.

1. CERA FLAVA or *Yellow Wax*. This is obtained by slicing the comb taken from the hive, draining and afterwards expressing the honey, and melting the residue in boiling water, which is kept hot for some time in order to allow the impurities to separate, and either subside or be dissolved by the water. When the liquid cools the wax concretes, and, having been removed and again melted in boiling water, is strained and poured into pans or other suitable vessels. It is usually brought to market in round flat cakes

of considerable thickness. The druggists of Philadelphia are supplied chiefly from the Western States and North Carolina, especially the latter, and from Cuba. Some of inferior quality is imported from Africa.

In this state wax has a yellowish colour, an agreeable somewhat aromatic odour, and a slight peculiar taste. To the touch it is rather soft and unctuous, though of a firm solid consistence and brittle. It has a granular fracture; but when cut with a knife presents a smooth glossy surface, the lustre of which is so peculiar as when met with in other bodies to be called waxy. It does not adhere to the fingers, nor to the teeth when chewed, but is softened and rendered tenacious by a moderate heat. Its point of fusion is 142° F.; its specific gravity from 0.960 to 0.965. Its chemical properties will be detailed under the head of white wax. The colour, odour, and taste of yellow wax depend on some principle associated with it, but not constituting one of its essential ingredients.

Various adulterations have been practised, most of which may be readily detected. Meal, earth, and other insoluble substances, are at the same time discovered and separated by melting and straining the wax. When the fracture is smooth and shining instead of being granular, the presence of resin may be suspected. This is dissolved by cold alcohol, while the wax is left untouched. Tallow and suet are detected by the softness they communicate to the wax, and its unpleasant odour when melted.

Yellow wax is used in medicine chiefly as an ingredient of plasters and cerates.

2. CERA ALBA or *White Wax*. The colour of yellow wax is discharged by exposing it with an extended surface to the combined influence of air, light, and moisture. The process of bleaching it is carried on to a considerable extent in the vicinity of Philadelphia. The wax, previously melted, is made to fall in streams upon a revolving cylinder, kept constantly wet, upon which it concretes, forming thin ribband-like layers. These, having been removed, are spread upon linen cloths stretched on frames, and exposed to the air and light; care being taken to water and occasionally turn them. In a few days they are partially bleached; but to deprive the wax completely of colour it is necessary to repeat the whole process once, if not oftener. When sufficiently white it is melted and cast into small circular cakes. The colour may also be discharged by chlorine; but the wax is said to be somewhat altered.

Perfectly pure wax is white, shining, diaphanous in thin layers, inodorous, insipid, harder and less unctuous to the touch than the yellow, soft and ductile at 95° F., and fusible at about 155° , retaining its fluidity at a lower temperature. According to Saussure, its specific gravity in the solid state is 0.966, at 178° F. 0.834, and at 201° 0.8247. By a great heat it is partly volatilized, partly decomposed; and when flame is applied to its vapour, it takes fire and burns with a clear bright light. It is insoluble in water, and in cold alcohol or ether, but is slightly soluble in boiling alcohol and ether, which deposite it in great measure upon cooling. The essential and fixed oils dissolve it with facility; resin readily unites with it by fusion; and soaps are formed by the action of soda and potassa in solution. It is not affected by the acids at ordinary temperatures, but is converted into a black mass when boiled with concentrated sulphuric acid. Its ultimate constituents are carbon, hydrogen, and oxygen. Dr. John ascertained that it consists of two distinct proximate principles, one of which he called *cerin*, the other *myricin*. According to MM. Boudet and Boissenot, the former constitutes at least 70 per cent. of wax, melts at about 143° , dissolves in 16 parts of boiling alcohol, and is saponifiable with potassa, yielding margaric acid, a

little oleic acid, and a fatty matter insusceptible of saponification called *cerain*; the latter melts at 149° , is dissolved by 200 parts of boiling alcohol, and is not saponifiable by potassa. It is stated, however, by Hess, as the result of his experiments, that wax is one single proximate principle, only occasionally containing some oxidized wax, or *ceric acid* as he denominates it. (*Annal. der Pharm.* xxvii. 2.)

White wax has been adulterated with white lead and tallow. The former sinks to the bottom of the vessel when the wax is melted; the latter imparts to it a dull opaque appearance, and a disagreeable odour during fusion. Starch has been employed for the same purpose. It may be detected by dissolving the wax in oil of turpentine, in which starch is insoluble. Pereira says that pure wax is yellowish-white; and that the white bleached wax in circular cakes always contains spermaceti, which is added to improve its colour.

Medical Properties and Uses. Wax has little effect upon the system. Under the impression, however, that it sheaths the inflamed mucous membrane of the bowels, it has been occasionally prescribed in diarrhœa and dysentery; and it is mentioned by Dioscorides as a remedy in the latter complaint. By Poerner it is highly recommended in excoriations of the bowels, attended with pain and obstinate diarrhœa. His mode of using it is to melt the wax with oil of sweet almonds or olive oil, and, while the mixture is still hot, to incorporate it by means of the yolk of an egg with some mucilaginous fluid. The dose is about half a drachm, to be repeated three or four times a day. Another method is to form an emulsion by means of soap; but it is evident that this would be the most energetic ingredient of the mixture. Wax is sometimes used to fill cavities in carious teeth. Its chief employment, however, is in the formation of ointments, cerates, and plasters. It is an ingredient in almost all the officinal cerates, which, indeed, owe their general title to the wax they contain.

3. VEGETABLE WAX. Many vegetable products contain wax, or a substance closely analogous to it, as one of their constituents. It exists in the pollen of numerous plants; and forms the bloom or glaucous powder which covers certain fruits, and the coating of varnish with which leaves are sometimes supplied. In some plants it exists so abundantly as to be profitably extracted for use. Such is the *Ceroxylon Andicola*, a lofty palm growing on the Mountain of Quindiu in the South American Andes. Upon the trunk of this tree, in the rings left by the fall of the leaves, is a coating of wax-like matter, about one-sixth of an inch thick, which is removed by the natives and employed in the manufacture of tapers. It contains, according to Vauquelin, two-thirds of a resinous substance, and one-third of pure wax. (*Fée.*) But the form of vegetable wax in which the druggists of this country are particularly interested, is that derived from the *Myrica cerifera*, and commonly called *myrtle wax*. (See *Bigelow's Am. Med. Bot.* iii. 32.) The wax myrtle is an aromatic shrub, from one to twelve feet in height, found in almost all parts of the United States from New England to Louisiana. The fruit, which grows in clusters closely attached to the stems and branches, is small, globular, and covered with a whitish coating of wax, which may be separated for use. Other parts of the plant are said to possess medical virtues. The bark of the root is acrid and astringent, and in large doses emetic, and has been popularly employed as a remedy in jaundice. (See *Bigelow's Med. Bot.* and *Thacher's Dispens.*) The process for collecting the wax is simple. The berries are boiled in water, and the wax, melting and floating on the surface, is either skimmed off and strained, or allowed to concreate as the liquor cools, and removed in the solid state.

To render it pure, it is again melted and strained, and then cast into large cakes. It is collected in New Jersey, but more abundantly in New England, particularly Rhode Island, whence it is exported to other parts of the country.

Myrtle wax is of a pale grayish-green colour, somewhat diaphanous, more brittle and at the same time more unctuous to the touch than beeswax, of a feeble odour, and a slightly bitterish taste. It is about as heavy as water, and melts at 109° F. It is insoluble in water, scarcely soluble in cold alcohol, soluble, with the exception of about thirteen per cent., in twenty parts of boiling alcohol, which deposits the greater portion upon cooling, soluble also in boiling ether, and slightly so in oil of turpentine. In chemical relations it bears a close resemblance to beeswax, and consists, like that product, of cerin and myricin, containing 87 parts of the former and 13 of the latter in the 100. The green colour depends upon a distinct principle, which may be separated by boiling the wax with ether and allowing the liquid to cool. The wax is deposited colourless, while the ether remains green. It is probable that the bitter taste also depends upon a principle distinct from the wax itself.

Medical Properties and Uses. This variety of wax has been popularly employed in the United States as a remedy for dysentery; and we are told by Dr. Fahnestock, that he found great advantage from its use in numerous cases during an epidemic prevalence of this complaint. He gave the powdered wax in doses of a teaspoonful frequently repeated, mixed with mucilage or syrup. (*Am. Journ. Med. Scien.* ii. 313.) It is occasionally substituted by apothecaries for beeswax in the formation of plasters, and is used in the preparation of tapers and candles. It is somewhat fragrant when burning, but emits a less brilliant light than common lamp-oil.

W.

CEREVISIÆ FERMENTUM. *Lond., Dub.*

Yeast.

Levure, Fr.; Bierhefen, Germ.; Fermento di cervogia, Ital.; Espuma de cerveza, Span.

This is the substance which rises, in the form of froth, to the surface of beer, and subsides to the bottom, during the process of fermentation. A similar substance is always produced during the vinous fermentation of saccharine liquids; but the principles of its formation are unknown.

It is a flocculent, frothy, somewhat viscid, semi-fluid, of a dirty yellowish colour, a sour vinous odour, and a bitter taste. At a temperature of 60° or 70°, in a close vessel or damp atmosphere, it soon undergoes putrefaction. Exposed to a moderate heat, it loses its liquid portion, becomes dry, hard, and brittle; and may in this state be preserved for a long time. In France it is brought to the solid state by introducing it into sacs, washing it with water, then submitting it to pressure, and ultimately drying it.

Yeast is insoluble in alcohol or water. It was analyzed by Westrumb, and found to contain in 15142 parts, 13 of potassa, 15 of carbonic acid, 10 of acetic acid, 45 of malic acid, 69 of lime, 240 of alcohol, 120 of extractive, 240 of mucilage, 315 of saccharine matter, 480 of gluten, 13595 of water, besides traces of silica and phosphoric acid. Its bitterness is attributable to a principle derived from the hops. The property for which it is chiefly valued is that of exciting the vinous fermentation in saccharine liquids, and the panary fermentation in various farinaceous substances. This property it owes to the azotized principle or gluten which it contains; for if separated

from this constituent, it loses its powers as a ferment, and re-acquires them upon the subsequent addition of the gluten. By boiling in water it is deprived of the property of exciting fermentation. At an elevated temperature it is decomposed, affording products similar to those which result from the decomposition of animal matters.

Examined by a microscope, yeast is found to abound in minute transparent vesicles, which appear to contain one or more granules. These have been supposed to be living infusory plants or animalcules, which have the power of propagating themselves at the expense of sugar and other organic proximate principles with which they may be brought into contact; and attempts have been made to solve the mysteries of fermentation by the conjecture that the sugar or other fermenting substance, while contributing to the nourishment of these microscopic beings, undergoes a decomposition resulting in the formation of new products, by a different arrangement of their elements. This theory, however, is not generally admitted;—the doctrine of Liebig, that fermentation is merely a chemical movement excited by a movement of decomposition going on in the ferment, being at present the one most in vogue.

Medical Properties and Uses. Yeast has been highly extolled as a remedy in typhoid fevers, and is said to have been given with advantage in hectic. It is, however, little employed, as its somewhat tonic and stimulant effects, ascribable to the bitter principle of hops, the alcohol, and the carbonic acid which are among its constituents, may be obtained with equal certainty from more convenient medicines. Dr. Hewson, of Philadelphia, informs us, that in a case of typhoid fever attended with great irritability of the stomach, the patient was benefitted and sustained by taking a pint of yeast daily for five days, during which period no other remedy was employed. When largely taken, it generally proves laxative; and it may sometimes be necessary to obviate this effect by opium. Externally applied, it is very useful in foul and sloughing ulcers, the fetor of which it corrects, while it affords a gentle stimulus to the debilitated vessels. It is usually employed mixed with farinaceous substances in the form of a cataplasm.

The dose is from half a fluidounce to two fluidounces every two or three hours.

Off. Prep. Cataplasma Fermenti, *Lond., Dub.*

W.

CETACEUM. *U.S., Lond., Ed., Dub.*

Spermaceti.

“A peculiar concrete substance obtained from *Physeter macrocephalus*.” *U.S.* “*Physeter Macrocephalus. Concretum in propriis capitis cellis repertum.*” *Lond.* “Cetine of *Physeter macrocephalus*, nearly pure.” *Ed.*

Blanc de baleine, *Spermaceti*, *Cetine*, *Fr.*; Wallrath, *Germ.*; *Spermaceti*, *Ital.*; *Esperma de bellena*, *Span.*

The spermaceti whale is from sixty to eighty feet in length, with an enormous head, not less in its largest part than thirty feet in circumference, and constituting one-third of the whole length of the body. The upper part of the head is occupied by large cavities, separated from each other by cartilaginous partitions, and containing an oily liquid, which, after the death of the animal, concretes into a white unctuous spongy mass, consisting of the proper spermaceti mixed with oil. This mass is removed from the cavities, and the oil allowed to separate by draining. The quantity of crude spermaceti thus obtained from a whale of the ordinary size, is more than sufficient

to fill twelve large barrels. It still, however, contains much oily matter and other impurities, from which it is freed by expression, washing with hot water, melting, straining, and lastly by repeated washing with a weak boiling ley of potash. The common whale oil, and the oil of other cetaceous animals, contain small quantities of spermaceti, which they slowly deposite on long standing.

Spermaceti is in white, pearly, semitransparent masses, of a crystalline foliaceous texture; friable, soft and somewhat unctuous to the touch; slightly odorous; insipid; of the sp. gr. 0·943; fusible at 112° F. (*Bostock*); volatilizable at a higher temperature without change *in vacuo*, but partially decomposed if the air is admitted; inflammable; insoluble in water; soluble in small proportion in boiling alcohol, ether, and oil of turpentine, but deposited as the liquids cool; readily soluble in the fixed oils; forming an imperfect soap when heated with the pure alkalies, by which it is converted into the margaric and oleic acids, and a peculiar substance named *ethal* by Chevreul; not affected by the mineral acids, except the sulphuric, which decomposes and dissolves it; rendered yellowish and rancid by long exposure to hot air, but capable of being again purified by washing with a warm ley of potash. By Fourcroy, spermaceti was supposed to be identical with adipocire, but Chevreul proved it to be a distinct principle, and proposed for it the name of *ctin*, which has been adopted in France. As found in the shops it is not entirely pure, containing a fixed oil, and often a peculiar colouring principle. From these it is separated by boiling in alcohol, which on cooling deposits the *ctin* in crystalline scales. In this state it does not melt under 120° F., is insoluble in 40 parts of alcohol of the sp. gr. 0·821 (*Thenard*); and is harder, more shining, and less unctuous to the touch than ordinary spermaceti. The ultimate constituents of spermaceti are, according to Berard, carbon 81, oxygen 6, hydrogen 13, in 100 parts; according to Saussure, carbon 75·074, hydrogen 12·795, oxygen 11·377, and nitrogen 0·354.

Medical Properties and Uses. Like the fixed oils, spermaceti has been given as a demulcent in irritations of the pulmonary and intestinal mucous membranes; but it possesses no peculiar virtues, and its internal use has been generally abandoned. It may be reduced to powder by the addition of a little alcohol or almond oil, or suspended in water by means of mucilage, or the yolk of eggs and sugar. Externally it is much employed as an ingredient of ointments and cerates.

CETRARIA. *U. S., Lond., Ed.*

Iceland Moss.

“*Cetraria Islandica.*” *U. S., Lond., Ed.*

Off. Syn. LICHEN ISLANDICUS. CETRARIA ISLANDICA.

Planta. Dub.

Lichen d'Islande, *Fr.*; Islandisches Moos, *Germ.*; Lichene Islandico, *Ital.*; Liquen Islandico, *Span.*

CETRARIA. *Sex. Syst.* Cryptogamia Lichenes.—*Nat. Ord.* Lichenaceæ.

Gen. Ch. Plant cartilagino-membranous, ascending or spreading, lobed, smooth, and naked on both sides. *Apothecia* shield-like, obliquely adnate with the margin, the disk coloured, plano-concave; border inflexed, derived from the frond. *Loudon's Encyc.*

The genus *Lichen* of Linnæus has been divided by subsequent botanists into numerous genera, which have been raised to the dignity of a distinct order, both in the natural and artificial systems of arrangement. The name *Cetraria* was conferred by Acharius on the genus to which the Iceland moss belongs.

Cetraria Islandica. Acharius, *Lichenog. Univ.* 512.—*Lichen Islandicus.* Woodv. *Med. Bot.* p. 803. t. 271. Iceland moss is foliaceous, erect; from two to four inches high, with a dry, coriaceous, smooth, shining, lacinated frond or leaf, the lobes of which are irregularly subdivided, channeled, and fringed at their edges with rigid hairs. Those divisions upon which the fruit is borne are dilated. The colour is olive-brown or greenish-gray above, reddish at the base, and lighter on the under than the upper surface. The fructification is in flat, shield-like, reddish-brown receptacles, with elevated entire edges, placed upon the surface of the frond near its border.

The plant is found in the northern latitudes of the old and new continents, and on the elevated mountains further south. It received its name from the abundance in which it prevails in Iceland. It is also abundant on the mountains and in the sandy plains of New England.

The dried moss is of diversified colour, grayish-white, brown, and red in different parts, with less of the green tint than in the recent state. It is inodorous, and has a mucilaginous, bitter taste. Macerated in water it absorbs rather more than its own weight of the fluid, and, if the water be warm, renders it bitter. Boiling water extracts all its soluble principles. The decoction thickens upon cooling, and acquires a gelatinous consistence, resembling that of starch in appearance, but without its viscosity. After some time the dissolved matter separates, and when dried forms semitransparent masses, insoluble in cold water, alcohol, or ether, but soluble in boiling water, and in solution forming a blue compound with iodine. This principle resembles starch in its general characters, but differs from it in some respects, and has received the distinctive name of *lichenin*. The most accurate analysis of Iceland moss is that by Berzelius. By this chemist 100 parts were found to afford 1.6 of chlorophylle, 3.0 of a peculiar bitter principle, 3.6 of uncrystallizable sugar, 3.7 of gum, 7.0 of the apotheme of extractive, 44.6 of the peculiar starch-like principle, 1.9 of the bilichenates of potassa and lime mixed with phosphate of lime, and 36.2 of amylaceous fibrin—the excess being 1.6 parts. (*Traité de Chim.* vi. 251.)

The name of *cetrarin* has been conferred on the bitter principle of Iceland moss. The following process for obtaining it is that of Dr. Herberger, who is said to have been the first to procure it in a pure state. The moss, coarsely powdered, is boiled for half an hour in four times its weight of alcohol of 0.883. The liquid, when cool, is expressed and filtered, and treated with diluted muriatic acid in the proportion of three drachms to every pound of moss employed. Water is then added in the quantity of about four times the bulk of the liquid, and the mixture left for a night in a closed matrass. The deposit which forms is collected on a filter, allowed to drain as much as possible, and submitted to the press. To purify it, the mass, while still moist, is broken into small pieces, washed with alcohol or ether, and treated with two hundred times its weight of boiling alcohol, which dissolves the cetrarin, leaving the other organic principles by which it has been hitherto accompanied. The greater part is deposited as the liquor cools, and the remainder may be obtained by evaporation. By this process one pound of moss yielded to Dr. Herberger 133 grains of cetrarin. This principle is white, not crystalline, light, unalterable in the air, inodor-

ous, and exceedingly bitter, especially in alcoholic solution. Its best solvent is absolute alcohol, of which 100 parts dissolve 1·7 of cetrarin at the boiling temperature. Ether also dissolves it, and it is slightly soluble in water. Its solutions are quite neutral to test paper. It is precipitated by the acids, and rendered much more soluble by the alkalies. Concentrated muriatic acid changes its colour to a bright blue. It precipitates the salts of iron, copper, lead, and silver. In the dose of two grains repeated every two hours it has been used successfully in intermittent fever. (See *Journ. de Pharm.* xxiii. 505, and *Am. Journ. of Pharm.* x. 54.)

The gum and starch contained in the moss render it sufficiently nutritive to serve as food for the inhabitants of Iceland and Lapland, who employ it powdered and made into bread, or boiled with milk, having first partially freed it from the bitter principle by repeated maceration in water. The bitterness may be entirely extracted by macerating the powdered moss, for twenty-four hours, in twenty-four times its weight of a solution formed with 1 part of an alkaline carbonate and 375 parts of water, decanting the liquid at the end of this time, and repeating the process with an equal quantity of the solution. The powder being now dried is perfectly sweet and highly nutritive. This process was suggested by Berzelius.

Medical Properties and Uses. Iceland moss is at the same time demulcent, nutritious, and tonic, and therefore well calculated for affections of the mucous membrane of the lungs and bowels, in which the local disease is associated with a debilitated condition of the digestive organs, or of the system generally. Hence it has been found useful in chronic catarrhs, and other pulmonary affections attended with copious and debilitating expectoration, especially when the matter discharged was of a purulent character; as also in dyspepsia, chronic dysentery, and diarrhœa. It has, moreover, been given in cases of debility succeeding acute disease, or dependent on copious purulent discharge from external ulcers. But the complaint in the treatment of which it has acquired most reputation is pulmonary consumption. It had long been employed in this disease, and in hæmoptysis, by the Danish physicians, before it became known to the profession at large. In the latter half of the last century it was introduced into extensive use; and numerous cases of cures supposed to have been effected by it are on record. But now that the pathology of consumption is understood, physicians have ceased to expect material advantage from it in the genuine tuberculous form of the disease; and there is reason to believe that the cases which have recovered under its use, were nothing more than chronic bronchitis or chronic inflammation of the pulmonary tissue. It can act only as a mild, nutritious, demulcent tonic; and certainly exercises no specific influence over tuberculous disease.

It is usually employed in the form of decoction. (See *Decoctum Cetrariæ*.) By some writers it is recommended to deprive it of the bitter principle by maceration in water, or a weak alkaline solution, before preparing the decoction, but we thus reduce it to the state of a simple demulcent, or mild article of diet, in which respect it is not superior to the ordinary farinaceous or gummy substances used in medicine. The powder is sometimes given in the dose of thirty grains or a drachm; and a preparation has obtained some repute, in which the ground moss is incorporated with chocolate, and used at the morning and evening meal as an ordinary beverage.

W.

CHENOPODIUM. U.S.

Wormseed.

“The fruit of *Chenopodium anthelminticum*.” U.S.

CHENOPODIUM. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Chenopodiaceæ.

Gen. Ch. Calyx five-leaved, five-cornered. Corolla none. Seed one, lenticular, superior. *Willd.*

Chenopodium anthelminticum. Willd. *Sp. Plant.* i. 1304; Barton, *Med. Bot.* ii. 183. This is an indigenous perennial plant, with an herbaceous, erect, branching, furrowed stem, which rises from two to five feet in height. The leaves are alternate or scattered, sessile, oblong lanceolate, attenuated at both ends, sinuated and toothed on the margin, conspicuously veined, of a yellowish-green colour, and dotted on their under surface. The flowers are very numerous, small, of the same colour with the leaves, and arranged in long, leafless, terminal panicles, which are composed of slender, dense, glomerate, alternating spikes.

This species of *Chenopodium*, known commonly by the name of *wormseed*, and *Jerusalem oak*, grows in almost all parts of the United States, but most vigorously and abundantly in the southern section. It is usually found in the vicinity of rubbish, along fences, in the streets of villages, and in the commons about the larger towns. It flowers from July to September, and ripens its seeds successively through the autumn. The whole herb has a strong, peculiar, offensive, yet somewhat aromatic odour, which it retains when dried. All parts of the plant are occasionally employed; but the fruit only is strictly officinal. This should be collected in October.

Wormseed, as found in the shops, is in small grains, not larger than the head of a pin, irregularly spherical, very light, of a dull, greenish-yellow or brownish colour, a bitterish, somewhat aromatic, pungent taste, and possessed to a high degree of the peculiar smell of the plant. These grains, when deprived, by rubbing them in the hand, of a capsular covering which invests the proper seed, exhibit a shining surface of a very dark colour. They abound in a volatile oil, upon which their sensible properties and medical virtues depend, and which is obtained separate by distillation. (See *Oleum Chenopodii*.) The same oil impregnates to a greater or less extent the whole plant.

The fruit of the *Chenopodium ambrosioides*, which is also an indigenous plant, and very prevalent in the Middle States, is said to be used indiscriminately with that of the *C. anthelminticum*. It may be distinguished by its odour, which is weaker and less offensive, and to some persons agreeable. The plant itself is often confounded with the true wormseed, from which it differs in having its flowers in leafy racemes. This species of *Chenopodium* has been employed in Europe as a remedy in nervous affections, particularly chorea. Five or six cases of this disease, reported by Plenck, yielded, after having resisted the ordinary means, to the daily use of an infusion of two drachms of the plant in ten ounces of water, taken in the dose of a cupful morning and evening, and associated with the employment of peppermint. (Merat and De Lens, *Dict. de Mat. Med.*)

The *C. Botrys*, which is also known by the vulgar name of *Jerusalem oak*, is another indigenous species, possessing anthelmintic virtues. The plant is said to have been used in France with advantage as a pectoral in catarrh and humoral asthma.

Medical Properties and Uses. Wormseed is one of our most efficient indigenous anthelmintics, and is thought to be particularly adapted to the expulsion of lumbrici in children. A dose of it is usually given before breakfast in the morning, and at bed time in the evening, for three or four days successively, and then followed by calomel or some other brisk cathartic. If the worms are not expelled, the same plan is repeated. The medicine is most conveniently administered in powder, mixed with syrup in the form of an electuary. The dose for a child two or three years old, is from one to two scruples. The volatile oil is perhaps more frequently given than the fruit in substance, though its offensive odour and taste sometimes render it of difficult administration. The dose for a child is from five to ten drops, mixed with sugar, or in the form of emulsion. A tablespoonful of the expressed juice of the leaves, or a wineglassful of a decoction prepared by boiling an ounce of the fresh plant in a pint of milk, with the addition of orange-peel or other aromatic, is sometimes substituted in domestic practice for the ordinary dose of the fruit and oil.

CHIMAPHILA. U.S., Lond.

Pipsissewa.

“The leaves of *Chimaphila umbellata*.” U. S. “*Chimaphila corymbosa*. *Folia*.” Lond.

Off. Syn. PYROLA. Herb of *Chimaphila umbellata*. *Ed.*; PYROLA UMBELLATA. *Herba*. *Dub.*

CHIMAPHILA. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Pyrolaceæ.

Gen. Ch. Calyx five-toothed. *Petals* five. *Style* very short, immersed in the germ. *Stigma* annular, orbicular, with a five-lobed disk. *Filaments* stipitate; stipe discoid, ciliate. *Capsules* five-celled, opening from the summits, margins unconnected. *Nuttall*.

This genus was separated from the *Pyrola* by Pursh, and is now admitted by most botanical writers. It embraces two species, the *C. umbellata* and *C. maculata*, which are both indigenous, and known throughout the country by the common title of *winter green*. The generic title was founded upon the vulgar name of the plants. It is formed of two Greek words, *χειμα* winter, and *φίλος* a friend. The *C. umbellata* only is official.

Chimaphila umbellata. Barton, *Med. Bot.* i. 17.—*Pyrola umbellata*. Willd. *Sp. Plant.* ii. 622; Bigelow, *Am. Med. Bot.* ii. 15. The pipsissewa is a small evergreen plant, with a perennial, creeping, yellowish root (rhizoma), which gives rise to several simple, erect or semi-procumbent stems, from four to eight inches in height, and ligneous at their base. The leaves are wedge-shaped, somewhat lanceolate, serrate, coriaceous, smooth, of a shining sap-green colour on the upper surface, paler beneath, and supported upon short footstalks, in irregular whorls, of which there are usually two on the same stem. The flowers are disposed in a small terminal corymb, and stand upon nodding peduncles. The calyx is small, and divided at its border into five teeth or segments. The corolla is composed of five roundish, concave, spreading petals, which are of a white colour tinged with red, and exhale an agreeable odour. The stamens are ten, with filaments shorter than the petals, and with large, nodding, bifurcated, purple anthers. The germ is globular and depressed, supporting a thick and apparently sessile stigma, the style being short and immersed in the germ. The seeds are numerous, linear, chaffy, and enclosed in a roundish, depressed, five-celled, five-valved capsule, having the persistent calyx at the base.

This humble but beautiful evergreen is a native of the northern latitudes of America, Europe, and Asia. It is found in all parts of the United States, and extends even to the Pacific ocean. It grows under the shade of woods, and prefers a loose sandy soil, enriched by decaying leaves. The flowers appear in June and July. All parts of the plant are endowed with active properties. The leaves and stems are kept in the shops.

The *C. maculata*, or *spotted winter green*, probably possesses similar virtues with the *C. umbellata*. The character of the leaves of the two plants will serve to distinguish them. Those of the *C. maculata* are lanceolate, rounded at the base, where they are broader than near the summit, and of a deep olive green colour, veined with greenish white; those of the officinal species are broadest near the summit, gradually narrowing to the base, and of a uniform shining green. In drying, with exposure to light, the colour fades very much, though it still retains a greenish hue.

Pipsissewa, when fresh and bruised, exhales a peculiar odour. The taste of the leaves is pleasantly bitter, astringent, and sweetish; that of the stems and root unites with these qualities a considerable degree of pungency. Boiling water extracts the active properties of the plant, which are also imparted to alcohol. The constituents, so far as ascertained, are bitter extractive, tannin, resin, gum, lignin, and saline matters. The active principle has not yet been isolated, though it probably exists in the substance called bitter extractive.

Medical Properties and Uses. This plant is diuretic, tonic, and astringent. It was employed by the aborigines in various complaints, especially scrofula, rheumatism, and nephritic affections. From their hands it passed into those of the European settlers, and was long a popular remedy in certain parts of the country, before it was adopted by the profession. The first regular treatise in relation to it that has come to our knowledge, was the thesis of Dr. Mitchell, published in the year 1803; but little was thought of it till the appearance of the paper of Dr. Sommerville, in the 5th vol. of the London Medico-Chirurgical Transactions. By this writer it was highly recommended as a remedy in dropsy; and his favourable report has been sustained by the subsequent statements of many respectable practitioners. It is particularly useful in cases attended with disordered digestion and general debility, in which its tonic properties and general acceptability to the stomach prove highly useful auxiliaries to its diuretic powers. Nevertheless, it cannot be relied on exclusively in the treatment of the complaint; for though it generally produces an increased flow of urine, it has seldom effected cures. Other disorders, in which it is said to have proved useful, are calculous and nephritic affections, and in general all those complaints of the urinary passages for which *uva ursi* is prescribed. It is very highly esteemed by some practitioners as a remedy in scrofula, both before and after the occurrence of ulceration; and it has certainly proved highly advantageous in certain obstinate ill-conditioned ulcers and cutaneous eruptions, supposed to be connected with a strumous diathesis. In these cases it is used both internally, and locally as a wash.

The decoction is the preparation usually preferred. It is made by boiling two ounces of the fresh bruised leaves with three pints of water to a quart, and given to the amount of a pint in twenty-four hours. The watery extract may be given in the dose of twenty or thirty grains four times a day.

CHIRETTA. *Ed.**Chiretta.*

“Herb and root of *Agathotes Chirayta*.” *Ed.*

AGATHOTES. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Gentianaceæ.

Gen. Ch. *Corolla* withering, rotate, in æstivation twisted to the right; with glandular hollows protected by a fringed scale upon the segments. *Anthers* not changing. *Stigmas* sessile. *Capsules* conical, one-celled, with spongy placenta upon the sutures. *Seeds* indefinite, minute. (*Lindley*.)

Agathotes Chirayta. Don, *Lond. Phil. Mag.* 1836, p. 76.—*Gentiana Chirayta*. Fleming, *Asiat. Research.* xi. 167. The *chirayta* or *chiretta* is an annual plant, about three feet high, with an erect, smooth, round stem, branching into an elegant leafy panicle, and furnished with opposite, embracing, lanceolate, very acute, entire, smooth, three or five-nerved leaves. The flowers are numerous, peduncled, yellow, with a four-cleft calyx having linear acute divisions, the limb of the corolla spreading and four-parted, four stamens, a single style, and a two-lobed stigma. The capsules are shorter than the permanent calyx and corolla. The plant is a native of Nepal, and other parts of Northern India. The whole of it is officinal. It is gathered about the time when the flowers begin to decay.

The dried plant is imported into Europe in bundles. The root is fibrous, and the stems contain a yellowish pith. In other respects it corresponds with the description above given. All parts of it have a very bitter taste, which is strongest in the root. It is without odour. Water and alcohol extract its virtues, which are also retained in the extract. According to Lassaigne and Boissel, the stems contain resin, a yellow bitter substance, brown colouring matter, gum, and various salts.

Medical Properties and Uses. *Chiretta* has long been used in India, where it is a favourite remedy with both the native and European practitioners. It has recently been introduced into Europe, where it appears to be highly esteemed; but has not been employed to any considerable extent in this country. Its properties are those of the pure bitters, and probably do not differ from those of the other members of the natural family of Gentianaceæ. (See *Gentiana*.) Like these, in overdoses it nauseates and oppresses the stomach. Some have supposed that, in addition to its tonic properties, it exerts a peculiar influence over the liver, promoting the secretion of bile and correcting it when deranged, and restoring healthy evacuations in cases of habitual costiveness. But it may well be doubted whether it produces any other effects of this kind than such as are incident to its tonic power, and might be expected from the other pure bitters. It has been used in dyspepsia, in the debility of convalescence, and generally in cases in which corroborant measures are indicated. In India it has been successfully employed in intermittents and remittents, combined with the seeds of the *Guilandina Bonduc*. It may be administered in powder, infusion, tincture, or extract. The dose in substance is twenty grains. The infusion is officinal.

CHONDRUS. U.S. Secondary.

Irish Moss.

“Chondrus crispus. (Greville, *Alg. Brit.*)” U.S.

CHONDRUS. *Sex. Syst.* Cryptogamia Algæ.—*Nat. Ord.* Algacæ.

Gen. Ch. Frond cartilaginous, dilating upwards into a flat, nerveless, dichotomously divided frond, of a purplish or livid-red colour. *Fructification*, subspherical capsules in the substance of the frond, rarely supported on little stalks, and containing a mass of minute free seeds. (Greville from *Lindley's Flor. Med.*)

Chondrus crispus. Greville, *Alg. Brit.* 129. t. 15.—*Sphærococcus crispus.* Agardh.—*Fucus crispus.* Linn. The *Irish moss*, or *carrageen*, as it is frequently called, consists of a flat, slender, cartilaginous frond, from two to twelve inches in length, dilated as it ascends until it becomes two or three lines in width, then repeatedly and dichotomously divided, with linear, wedge-shaped segments, and more or less curled up so as to diminish the apparent length. The capsules are somewhat hemispherical, and are imbedded in the disk of the frond. The plant grows upon rocks and stones on the coasts of Europe, and is especially abundant on the southern and western coasts of Ireland, where it is collected for use. It is said also to be a native of the United States.

When collected, it is washed and dried. In the recent state it is of a purplish colour, but, as found in the shops, is yellowish or yellowish-white, with occasionally purplish portions. It is translucent, of a feeble odour, and nearly tasteless. It swells up in cold water, but does not dissolve. Boiling water dissolves a large proportion of it, and, if the solution be sufficiently concentrated, gelatinizes on cooling. According to Feuchtwanger, it contains starch, and a large proportion of pectin, with compounds of sulphur, chlorine, and bromine, and some oxalate of lime. Herberger found 79.1 per cent. of vegetable jelly, and 9.5 of mucus, with fatty matter, free acids, chlorides, &c., but neither iodine nor bromine. The pectin or vegetable jelly, Pereira thinks entitled to the rank of a distinct proximate principle, and proposes to call *carrageenin*. It is distinguished from gum by affording when dissolved in water no precipitate with alcohol, from starch by not becoming blue with tincture of iodine, from pectin by yielding no precipitate with acetate of lead, and no mucic acid by the action of nitric acid.

Carrageen is nutritive and demulcent, and, being easy of digestion and not unpleasant to the taste, forms a useful article of diet in cases in which the farinaceous preparations, such as tapioca, sago, barley, &c., are usually employed. It has been particularly recommended in chronic pectoral affections, scrofulous complaints, dysentery, diarrhœa, and disorders of the kidneys and bladder. It may be used in the form of decoction, made by boiling a pint and a half of water with half an ounce of the moss down to a pint. Sugar and lemon juice may usually be added to improve the flavour. Milk may be substituted for water, when a more nutritious preparation is required. It is recommended to macerate the moss for about ten minutes in cold water before submitting it to decoction. Any unpleasant flavour that it may have acquired from the contact of foreign substances is thus removed. W.

CIMICIFUGA. U. S. Secondary.

Black Snakeroot.

"The root of *Cimicifuga racemosa*." U. S.

CIMICIFUGA. *Sex. Syst.* Polyandria Di-Pentagynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. *Calyx* four or five-leaved. *Petals* four to eight, deformed, thickish, sometimes wanting. *Capsules* one to five, oblong, many-seeded. *Seeds* squamose. *Nuttall.*

Cimicifuga racemosa. Torrey, *Flor.* 219.—*C. serpentaria.* Pursh, *Flor. Am. Sept.* p. 372.—*Actæa racemosa.* Willd. *Sp. Plant.* ii. 1139.—*Macrotys racemosa.* Eaton's *Manual*, p. 288. This is a tall, stately plant, having a perennial root, and a simple herbaceous stem, which rises from four to eight feet in height. The leaves are large, and ternately decomposed, having oblong ovate leaflets, incised and toothed at their edges. The flowers are small, white, and disposed in a long, terminal, wandlike raceme; with occasionally one or two shorter racemes near its base. The calyx is white, four-leaved, and deciduous; the petals are minute, and shorter than the stamens; the pistil consists of an oval germ and a sessile stigma. The fruit is an ovate capsule containing numerous flat seeds.

The *black snakeroot*, or *cohosh* as this plant is sometimes called, is a native of the United States, growing in shady and rocky woods, from Canada to Florida, and flowering in June and July. The root is the part employed.

This, as found in the shops, consists of a thick, irregularly bent or contorted body or caudex, from one-third of an inch to an inch in thickness, often several inches in length, furnished with many slender radicles, and rendered exceedingly rough and jagged in appearance by the remains of the stems of successive years, which to the length of an inch or more are frequently attached to the root. The colour is externally dark brown, almost black, internally whitish; the odour, though not strong, is very peculiar and rather disagreeable; the taste is bitter, herbaceous, and somewhat astringent, leaving a slight sense of acrimony. The root yields its virtues to boiling water. It was found by Mr. Tilghman, of Philadelphia, to contain gum, starch, sugar, resin, wax, fatty matter, tannin and gallic acid, a black colouring matter, a green colouring matter, lignin, and salts of potassa, lime, magnesia, and iron. (*Journ. of Phil. Col. of Pharm.* vi. 20.)

Medical Properties and Uses. The effects of *Cimicifuga* in health have not been very accurately investigated. It has been usually considered a mild tonic, with the property of stimulating the secretions, particularly those of the skin, kidneys, and bronchial mucous membrane; and has been thought by some to have an especial affinity for the uterus. It undoubtedly exercises considerable influence over the nervous system, probably of a sedative character; but this influence, so far as our observation has gone, is shown rather in morbid states of that system than in health. Dr. Hildreth has found it, in large doses, to produce some vertigo, impaired vision, nausea and vomiting, and a reduction of the circulation; but from very large quantities has seen no alarming narcotic effects. Its common name was probably derived from its supposed power of curing the disease arising from the bite of the rattlesnake. Till recently, it has been employed chiefly in domestic practice as a remedy in rheumatism, dropsy, hysteria, and various affections of the lungs, particularly those resembling consumption. Several

cases of chorea are recorded by Dr. Jesse Young, in which it is said to have effected cures; and the editor of the American Journal of the Medical Sciences states, that he was informed by Dr. Physick that he had known it, in the dose of ten grains every two hours, prove successful in the cure of this complaint in several instances. In the cases recorded by Dr. Young, the powdered root was given in the quantity of a teaspoonful three times a day. (*Am. Journ. of Med. Sciences*, ix. 310.) We have administered this medicine in chorea, with complete success, after the failure of purgatives and metallic tonics; and have also derived the happiest effects from it in a case of convulsions, occurring periodically, and connected with uterine disorder. Dr. Hildreth has found it, in combination with iodine, very advantageous in the early stages of phthisis. (*Am. Journ. of Med. Sci. N. S.* iv. 281.) It is usually administered in the form of decoction. An ounce of the bruised root may be boiled for a short time in a pint of water, and one or two fluidounces given for a dose. From half a pint to a pint of the decoction may be taken without inconvenience during the day. W.

Quinquina, Fr.; China, Peruvianische Rinde, Germ; China, Ital.; Quina, Span.

When this work was originally written, various points in relation to the botanical and pharmacological history of Peruvian Bark were unsettled, and appeared to require discussion. Since that period, the botanical part of the subject has been laboriously investigated by Professor Lindley, of London, whose conclusions are as satisfactory as the existing state of information will permit; and certain opinions in relation to the sources and character of different varieties of the drug, which were held by us in common with eminent pharmacologists of the continent of Europe, but, being wholly different from those of the highest British authorities, were thought to require whatever support we could give them, have now been adopted by the best writers of Great Britain, and may be considered as fully established. In the present edition, therefore, discussion upon these points may be spared as no longer necessary; and we shall content ourselves with stating the facts as now generally admitted.

Botanical History.

Though the use of Peruvian bark was introduced into Europe so early as 1640, it was not till the year 1737 that the plant which produced it was known to naturalists. In that year, La Condamine, one of the French Academicians who were sent to South America to make observations relative to the figure of the earth, on his journey to Lima, through the province of Loxa, had an opportunity of examining the tree, of which, upon his return, he published a description in the Memoirs of the Academy. Soon afterwards Linnæus gave it the name of *Cinchona officinalis*, in honour of the Countess of Cinchon, who is said to have first taken the bark to Europe; but, in his description of the plant, he is stated by Humboldt to have united the species discovered by La Condamine with the *C. pubescens*, a specimen of which had been sent him from Santa Fé de Bogota. For a long time botanists were ignorant that more than one species of this genus existed; and the *C. officinalis* continued, till a comparatively recent date, to be recognised by the Pharmacopœias as the only source of the Peruvian bark of commerce. But numerous plants supposed to belong to the genus were afterwards discovered in various parts of the world; and the number of distinct species for which the honour has been claimed, is not less than forty-six, exclusive of the varieties which have been mistaken for species by one or another botanist. But the propriety of associating all these plants in one genus has always been considered doubtful; and, according to De Candolle, there exist sufficient grounds for distributing them into at least eight genera; viz. *Cinchona*, *Buena*, *Remijia*, *Exostemma*, *Pinckneya*, *Hymenodyction*, *Luculia*, and *Danais*. The *Cinchona* is confined exclusively to the region of country now occupied by the republics of New Granada, Equador, Peru, and Bolivia. The *Buena* includes two Peruvian and one Brazilian species, the former of which, before their change of name, were designated as the *Cinchona acuminata*, and *C. obtusifolia*. The genus *Remijia* was established by De Candolle, and embraces three shrubs of Brazil, which were ascribed by Aug. de St. Hilaire to the *Cinchona*, and the bark of which is used as a febrifuge by the natives of the country. To the *Exostemma* belong the West India species, of which there are not less than nine, formerly known as the *Cinchona Caribæa*, *C. floribunda*, &c. To the same genus belong the former *Cinchona Philippica* of the Philippine islands, the *C. corymbifera* of Tongataboo, four species indigenous to Peru, and two discovered by M. de St. Hilaire in Brazil. The *Pinckneya* consists of a single species, inhabiting Georgia and South Carolina, discovered by Michaux the elder, and described in some botanical works by the name of *Cinchona Carolianiana*. The *Hymenodyction* is an East India genus, including the *Cinchona excelsa* of Roxburgh, found on the Coromandel coast. The *Luculia*, of which there is but one species—the *Cinchona gratissima* of Roxburgh's Flora Indica—inhabits the mountains of Nepaul. The *Danais* embraces the *Cinchona Afro-Inda* of Willem., growing in the Isle of France. Of these various genera, the *Cinchona*, *Buena* or *Cosmibuena* of Ruiz and Pavon, and the *Exostemma*, have been most generally confounded. The last, however, is decidedly distinguished by the projection of the stamens beyond the corolla, a character expressed in the name of the genus. The two former are still frequently combined by scientific writers. The *Buena* was originally suggested as a distinct genus by Ruiz and Pavon, has been recognised by De Candolle and some other authors, and appears to be sufficiently characterised. Its chief peculiarities are the shape of the

corolla, the separation of the calyx from the fruit at maturity, and the opening of the capsule from above downwards. We have briefly noticed these genera, which have at various times been confounded with the true *Cinchona*, because the barks of some of them have been occasionally substituted in pharmacy for the genuine febrifuge of Peru. We shall now proceed to consider the proper *Cinchonas*. It may be proper, however, first to say, that the botanists who have made personal observations upon these plants, besides *La Condamine*, of whom we have before spoken, are chiefly *Joseph de Jussieu*, who in the year 1739 explored the country about Loxa, and gathered specimens which are still existing in the cabinets of Europe; *Mutis*, who in the year 1772 discovered *Cinchona* trees in New Granada, and afterwards, aided by his pupil *Zea*, made further investigations and discoveries in the same region of country; *Ruiz* and *Pavon*, who in the year 1777 began a course of botanical inquiries in the central portions of Lower Peru, and discovered several new species; *Humboldt* and *Bonpland*, who visited several of the Peruvian bark districts, and published the results of their observations after 1792; and finally *Pöppig*, who travelled in Peru as late as 1832, and published an account of his journey about the year 1835.

CINCHONA. Sex. Syst. Pentandria Monogynia.—Nat. Ord. Cinchonaceæ.

Gen. Ch. Calyx five-toothed. *Corolla* hypocrateriform, with a five-parted limb, valvate in æstivation. *Anthers* linear, inserted within the tube, and not projecting, unless in a very slight degree. *Capsule* splitting through the dissepiment into two cocci open at the commissure, and crowned by the calyx. *Seeds* girted by a membranous lacerated wing. (*Lindley*.)

The plants composing this genus are trees or shrubs. The leaves are opposite, upon short petioles, with flat margins, and are attended with ovate or oblong, foliaceous, free, deciduous stipules. The flowers are terminal, in corymbose panicles, and of a white or purplish rose colour. (*De Candolle*.)

It has been stated that the genuine *cinchona* trees are confined exclusively to the continent of South America. Within these limits, however, they are very widely diffused, extending from La Paz, in the former vice-royalty of Buenos Ayres, to the mountainous regions of Santa Martha on the northern coast. Those which yield the bark of commerce grow at various elevations upon the Andes, seldom less than 4000 feet above the level of the sea; and require a temperature considerably lower than that which usually prevails in tropical countries.

There has been much difficulty in properly arranging the species of *Cinchona*; and botanists have not only differed among themselves on this point, but have in some instances exhibited a degree of excitement unbecoming the dignity of science. *Ruiz* and *Pavon*, in the *Flora Peruviana*, describe thirteen new species, while *Mutis* reduced the number to seven, and Professor *Zea* attempted to prove, that almost all the efficacious species of *Ruiz* and *Pavon* are reducible to the four described by *Mutis* in the year 1793, in the *Literary News* of Santa Fè de Bogota. It appears from the best testimony, that the number of the species has been unnecessarily augmented by certain botanists; mere fugitive differences, depending on peculiarities of situation or growth, having been exaggerated into permanent characteristics. One source of the difficulty of a proper discrimination is stated by *Humboldt* to be the varying shape of the leaves of the same species, according to the degree of elevation upon the mountainous declivities, to the severity or mildness of the climate, the greater or less humidity of the soil, and to various circumstances in the growth of individual plants. Even the same tree often produces foliage of a diversified character; and a person not aware of this fact, might be led to imagine that he had discovered different species

from an examination of the leaves which have grown upon one and the same branch. The fructification partakes, to a certain extent, of the same varying character; and the difficulty is thus still further augmented.

Lambert, in his "Illustration of the genus *Cinchona*," published in the year 1821, after admitting with Humboldt the identity of several varieties which had received specific names from other botanists, describes nineteen species, exclusive of the two Peruvian *Buenæ*. De Candolle enumerates only sixteen well ascertained species.

In the present state of our knowledge, it is impossible to decide from which species of *Cinchona* the several varieties of bark are respectively derived. The former references of the yellow bark to the *C. cordifolia*, of the pale to the *C. lancifolia*, and of the red to the *C. oblongifolia*, have been very properly abandoned in the United States and Edinburgh Pharmacopœias, though still retained in those of the London and Dublin Colleges. It is now almost universally admitted, that the valuable barks known in the market by these titles, are not the product of the species to which they have been ascribed. It is stated by Humboldt, that the property of curing agues belongs to the barks of all the cinchonas with hairy and woolly blossoms, and to those alone. In Lindley's catalogue this division includes fifteen species. We shall notice the most prominent, mentioning also the synonyms employed by different authors.

1. *Cinchona Condaminea*. Humb. and Bonpl. *Plant. Equin.* i. p. 33. t. 10; Lindley, *Flor. Med.* 414. This tree, when full grown, has a stem about eighteen feet high and a foot in thickness, with opposite branches, of which the lower are horizontal, and the higher rise upwards at their extremities. The bark of the trunk is ash-gray with clefts or fissures, and yields when wounded a bitter astringent juice; that of the small branches is greenish, smooth, and glossy, and easily separable from the wood. The leaves are of variable shape, but generally ovate-lanceolate, about four inches in length by less than two in breadth, smooth, and scrobiculate at the axils of the veins beneath. The flowers are in axillary, downy, corymbose panicles. The tree grows on the declivities of the mountains, at an elevation of from about a mile to a mile and a half, and in a mean temperature of 67° F. It was seen by Humboldt and Bonpland in the neighbourhood of Loxa, and is said also to grow near Guancabamba and Ayavaca in Peru. It is now generally admitted to be the source of the *crown bark of Loxa*, and is recognised as such by the Edinburgh College.

2. *C. micrantha*. Ruiz and Pavon. *Fl. Peruv.* ii. 52. t. 194; Lindley, *Flor. Med.* 412.—*C. scrobiculata*, Humb. and Bonpl. *Plant. Equin.* i. p. 165. t. 47. Lindley has no hesitation in uniting the *C. scrobiculata* of Humboldt and Bonpland with the *C. micrantha* of Ruiz and Pavon. It is a large tree, attaining the height of forty feet, with oblong leaves, from four to twelve inches in length and from two to six in breadth, scarcely acute, smooth, shining on the upper surface, and scrobiculate at the axils of the veins beneath. The flowers are in terminal, loose, leafless panicles, and are smaller than those of any other species except the *C. lancifolia*. (*Lindley*.) The tree was seen by Humboldt and Bonpland forming large forests in the mountains near the city of Jaen de Bracomoros. It grows also, according to Ruiz and Pavon, in the mountains near Chicoplaya, Monzon, and Puebla de San Antonio, and, according to Pöppig, at Cuchero. Large quantities of the bark are collected by the people of Jaen, and sent to the coast to be shipped to Lima; and Ruiz states that it is always mixed with that sent into the market from the provinces of Panatahuas, Huamiliés, and Huanuco. The Edinburgh College ascribes to this species their *Cinchona*

cinerea, the *gray* or *silver bark* of British commerce, frequently called also *Huanuco bark*. It undoubtedly contributes to furnish the officinal *pale bark*.

3. *C. lancifolia*. Mutis, *Period. de Santa Fe*, p. 465; Lindley, *Flor. Med.* 415.—*C. angustifolia*. Pavon, *Quinolog. Suppl.* p. 14. This species has been shorn of much of its honours by Lindley, who has separated from it the *C. nitida* and *C. lanceolata* of Ruiz and Pavon, the union of which with it by other botanists had given it an unmerited importance. As seen by Mutis, it is a very handsome tree, from thirty to forty-five feet in height, with a trunk from one to four feet in diameter. Its leaves are oblong-lanceolate, very acute at each end, revolute at the edge, smooth above, and not scrobiculate. The flowers, which are the smallest in the genus, are in five-flowered axillary cymes. (Lindley.) This species is a native of New Granada. The London and Dublin Colleges ascribe to it one of the officinal varieties of bark, under the impression, probably, that the species is identical with the *C. Condaminea*, and therefore affords the most esteemed pale bark of the shops. This, however, has been ascertained to be a mistake. The product of the *C. lancifolia* is one of the Carthagena barks, and is of inferior quality. It was named *orange bark*—*quina naranjanda*—by Mutis, and a specimen deposited by Humboldt, under this name, in the Museum of Natural History of Paris, was found by Guibourt to be identical with his *spongy Carthagena bark*. That the tree cannot produce one of the valuable varieties is proved by the fact, that none of these comes from Carthagena, through which the bark of the *C. lancifolia* must be exported.

4. *C. cordifolia*. Mutis, in *Humb. Magaz. Berlin*, 1807, p. 117; Lindley, *Flor. Med.* 839. This is a spreading tree, fifteen or twenty feet high, rising on a single, erect, round stem, which is covered with a smooth bark, of a brownish-gray colour. The bark of the smaller branches is lighter coloured. The leaves vary much in form, but some of a heart-shape are to be found on almost every branch. They are usually roundish-ovate, about nine inches long, smooth and shining on the upper surface, ribbed and pubescent on the under. The flowers are in thyrsoid, brachiate, tomentose panicles. This species was first discovered by Mutis in the mountains about Santa Fé de Bogota in New Granada, and grows at elevations varying from 5800 to 9500 feet. It is considered by the London and Dublin Colleges as the source of the *yellow bark* of the shops. It has been ascertained beyond the possibility of doubt, that it does not produce the valuable or officinal yellow bark, which never comes from the region where it is known to grow. Guibourt has found that the *quina amarilla de Santa Fé* or yellow bark of Santa Fé, which is probably produced by the *C. cordifolia*, is identical with *hard Carthagena bark*.

5. *C. magnifolia*. Ruiz and Pavon, *Fl. Peruv.* ii. 53. t. 196.—*C. oblongifolia*, Mutis.—There has been some confusion in relation to these two species. The London and Dublin Colleges, in recognising the *C. oblongifolia* as the source of the officinal red bark, undoubtedly had in view the plant discovered by Mutis in New Granada, at the same time that the former college gives the authority of Lambert for the name. Now Lindley has ascertained that the *C. oblongifolia* of Lambert is in fact a different plant from that of Mutis of the same name, and believes with the authors of the *Flora Peruviana*, that the latter is identical with their *C. magnifolia*. We shall, therefore, take it for granted, that this is the plant intended by the London College, the bark of the *C. oblongifolia* of Lambert being wholly unknown. The *C. oblongifolia* of Mutis is a stately tree with very large leaves, which are oblong, strongly ribbed, smooth and shining on both surfaces, and often a foot in length exclusive of the footstalk. The flowers

are in large, terminal, leafless thyrses, and have a fragrant odour, not unlike that of orange-blossoms, from which circumstance, the tree has received the name of *Cascarillo de Flor de Azahar*. This species grows in New Granada, and, according to Ruiz and Pavon, is abundant also on the mountains of Panatahuas, about Cuchero, Chinca, Chacahuassi, &c. Some years since, it was considered as indisputably the source of the best red bark of commerce, ascribed to it by the London and Dublin Pharmacopœias. A little reflection might have convinced those acquainted with the commerce in bark, that this reference was incorrect; for who ever hears of the officinal red bark as coming from Carthagena? and yet this is the port from which the product of the *C. oblongifolia*, growing in New Granada, is shipped. The tree does, undoubtedly, as asserted by Mutis, produce a red bark; but it is the *red Carthagena bark*, the *quina roxa de Santa Fé* of Ruiz, a comparatively valueless variety, wholly distinct from the efficient red bark brought from the Pacific, and so highly esteemed as a febrifuge. Ruiz speaks of it as of inferior quality and little esteemed; and Bergen and Guibourt have proved it to be identical with the worthless *quina nova* or *new bark* of European commerce.

The foregoing species have been particularly noticed, because recognised in some of the Pharmacopœias as the sources of officinal varieties of bark. The following, for a description of which we refer to Lindley's *Flora Medica*, yield barks possessing febrifuge properties.—6. *C. nitida* of the *Flora Peruviana*, incorrectly confounded, according to Lindley, with *C. lanceolata* by De Candolle, and *C. Condaminea* by Lambert, grows in groves, in cold situations upon the Andes, in the Peruvian provinces of Huanuco, Tarma, Huamiles, and Xauxa, and affords a bark which is very highly esteemed in those places, though unknown as a distinct variety in commerce.—7. *C. lucumæfolia* of Pavon, confounded by Lambert with *C. Condaminea*, grows near Loxa, and probably contributes to the Loxa or pale barks.—8. *C. lanceolata* of the *Flora Peruviana*, is found at Cuchero and various other places fifteen or twenty leagues distant from Huanuco, where it forms groves in lofty cold situations upon the Andes. Its bark is said by Ruiz and Pavon to be called *yellow bark*, from the colour of its inner surface, and to resemble Calisaya bark in flavour. Ruiz, indeed, conjectures that it is the source of that highly valued variety of bark, in which case, the tree must also grow in Bolivia at a great distance from its known locality.—9. *C. ovalifolia* of Humboldt and Bonpland, the *C. Humboldtiana* of Rœm. and Schult., and of De Cand., is a shrub from six to nine feet high, inhabiting the province of Cuenca, where it forms considerable forests. It probably contributes to the Loxa barks, although its product is said to be of inferior quality.—10. *C. ovata* of the *Fl. Peruv.* grows in close groves, in warm situations, at the foot of the Andes, near Pozuzo and Panao, about ten leagues from Huanuco. Lindley considers it quite distinct from the *C. pubescens* of Vahl, and *C. cordifolia* of Mutis, with both of which it has been confounded. Ruiz calls its bark *cascarillo pallido* or *pale bark*, and states that it was not to be found in commerce, though employed at Panao in the preparation of an extract of cinchona. Von Bergen, however, upon comparing a specimen of the *cascarillo pallido* in the collection of Ruiz with the Jaen bark, found them identical in character.—11. *C. pubescens* of Vahl, considered by Lindley as identical with the *C. purpurea* of the *Fl. Peruv.*, is a tree of considerable magnitude, distinguished by the violet tint of its large leaves, and the purple colour of its flowers. It occurs in groves on the lower mountain ridges in the provinces of Loxa, Jaen, Panatahuas, &c., was seen by Pöppig at Cuchuo, and is said to grow also in New Granada. The bark is of inferior quality,

and is said to be employed for adulterating the better kinds. A specimen taken to Europe by Pöppig, was found by Reichel to be identical with the Huamiliés bark of commerce.—12. *C. hirsuta* of the Fl. Peruv. grows on wooded mountains in the province of Panatahuas near Huanuco, and is said to yield a good bark, called formerly *quina delgadilla* or *delgada*, but now scarcely collected.—13. *C. glandulifera* of the Fl. Peruv. is a shrub of about twelve feet, flourishing on the high mountains of the region N. W. of Huanuco, and yielding an excellent bark, unknown in commerce, called by the inhabitants *cascarillo negrilla* from its blackish epidermis. In its flowering season, it perfumes the forests by the strong scent of its blossoms.—14. *C. acutifolia* of the Fl. Peruv., discovered by Tafalla in the Peruvian Andes, north of Huanuco, yields a very inferior bark, said by Ruiz and Pavon sometimes to occur in parcels of the better kinds.—15. *C. macrocarpa* of Vahl, identical, according to Ruiz and Pavon, with the *C. ovalifolia* of Mutis, is a shrub of about eight feet in height, forming considerable forests in the provinces of Loxa and Cuenca, found by Mutis in New Granada, and said to grow as far north as Santa Martha. Its bark is called *quina blanca* or white bark, probably from the colour of the epidermis, and is not highly esteemed. May not this species be the source of the commercial variety of Cinchona brought from Maracaybo and Santa Martha?

Besides the above species, Lindley enumerates, 16. *C. rotundifolia* of Ruiz and Pavon, growing in the province of Loxa; 17. *C. villosa* of Pavon, the *C. Humboldtiana* of Lambert, growing at Jaen of Loxa; 18. *C. oblongifolia* of Lambert, in the same locality; 19. *C. caduciflora* of Bonpland, growing near Jaen de Bracomoros; 20. *C. stenocarpa* of Lambert, inhabiting the mountains of Loxa; and 21. *C. cava* of Pavon, the *C. Pavonii* of Lambert, which is found in Quito. None of these are known to yield bark to commerce. The *C. dichotoma* of the *Flora Peruviana*, *C. macrocalyx* of De Candolle, *C. crassifolia* of Pavon in De Candolle's Prodrômus, *C. Pelalba* of the same authority, and *C. Muzonensis* of Goudot in De Candolle's Prodrômus, are considered by Lindley as uncertain species.

Commercial History.

For more than a century after Peruvian bark came into use, it was procured almost exclusively from Loxa and the neighbouring provinces. In a memoir published A. D. 1738, La Condamine speaks of the bark of Rhio-bambo, Cuenca, Ayavaca, and Jaén de Bracomoros. Of these places, the first two, together with Loxa, lie within the ancient kingdom of Quito, at its southern extremity; the others are in the same vicinity, within the borders of Peru. The drug was shipped chiefly at the Port of Payta, from which it was carried to Spain, and thence spread over Europe. Beyond the limits above mentioned, the Cinchona was not supposed to exist, till, in the year 1753, a gentleman of Loxa, familiar with the aspect of the tree, discovered it while on a journey from the place of his residence to Santa Fé de Bogota, in numerous situations along his route, wherever, in fact, the elevation of the country was equal to that of Loxa, or about 6,500 feet above the level of the sea. This discovery extended quite through Quito into the kingdom of New Granada, as far as two degrees and a half north of the equator. But no practical advantage was derived from it; and the information lay buried in the archives of the vice-royalty, till subsequent events brought it to light. To Mutis undoubtedly belongs the credit of making known the existence of the Cinchona in New Granada. He first discovered it in the neighbourhood of Bogota, in the year 1772. A botanical expedition was some time after-

wards organized by the Spanish government, with the view of exploring this part of their American dominions, and the direction of it was given to Mutis. The researches of the expedition eventuated in the discovery of several species of the *Cinchona* in New Granada, and a commerce in the bark soon commenced, which was afterwards increased, and carried on with great vigour through the ports of Carthagena and Santa Martha. The English and North Americans, opening a contraband trade with these ports, were enabled to undersell the Spanish merchant, who received his supplies by the circuitous route of Cape Horn; and the barks of New Granada were soon as abundant as those of Loxa in the markets of Europe.

To these sources another was added about the same time, A. D. 1776, by the discovery of the *Cinchona* in the centre of Peru, in the mountainous region about the city of Huanuco, which lies on the eastern declivity of the Andes, to the north-east of Lima, at least six degrees to the south of the province of Loxa. To explore this new locality, another botanical expedition was set on foot, at the head of which were Ruiz and Pavon, the distinguished authors of the *Flora Peruviana*. These botanists spent several years in this region, during which time they discovered numerous species that were afterwards described in their *Flora*. Lima became the entrepot for the barks collected around Huanuco; and hence probably originated the name of Lima bark, so often conferred, in common language, not only upon the varieties received through that city, but also upon the medicine generally.

Soon after the last mentioned discovery, two additional localities of the *Cinchona* were found, one at the northern extremity of the continent near Santa Martha, the other very far to the south, in the provinces of La Paz and Cochabamba, then within the vice-royalty of Buenos Ayres, now attached to the republic of Bolivia. These latter places became the source of an abundant supply of excellent bark, which received the name of Calisaya bark. It was sent partly to the ports on the Pacific, partly to Buenos Ayres.

The consequence of these discoveries, following each other in such rapid succession, was a vast increase in the supply of bark, which was now shipped from the ports of Guayaquil, Payta, Lima, Arica, Buenos Ayres, Carthagena, and Santa Martha. At the same time, the average quality was probably deteriorated; for, though many of the new varieties were possessed of excellent properties, yet equal care in superintending the collection and assorting of the article could not be exercised now that the field was so extended, as when it was confined to a small portion of the South of Quito and North of Peru. The varieties which were poured into the market soon became so numerous as to burthen the memory, if not to defy the discrimination of the druggist; and the best pharmacutists found themselves at a loss to discover any permanent peculiarities, which might serve as the basis of a proper and useful classification. This perplexity has continued more or less to the present time; though the discovery of the new alkaline principles has presented a ground of distinction which was before unknown. The restrictions upon the commerce with South America, by directing the trade into irregular channels, had also a tendency to deteriorate the character of the drug. In the complexity of contrivance to which it was necessary to resort, to deceive the vigilance of the government, little attention could be paid to a proper assortment of the several varieties; and not only were the best barks mixed with those of inferior species and less careful preparation, but the products of other trees, bearing no resemblance to the *Cinchona*, were sometimes added, having been artificially prepared so as to deceive a careless observer. The markets of this country were peculiarly ill furnished. The

supplies being derived chiefly, by means of a contraband trade, from Carthage and other ports on the Spanish Main, or indirectly through the Havana, were necessarily of an inferior character; and the little good bark which reached us was imported by our druggists from London, whither it was sent from Cadiz. A great change, however, in this respect, has taken place since the ports on the Pacific have been opened to our commerce. The best kinds of bark have thus been rendered directly accessible to us; and increased intelligence in the community has co-operated with the facility of supply, to exclude from our markets that kind of trash with which they were formerly glutted. Our ships trading to the Pacific, run along the American coast from Valparaiso to Guayaquil, stopping at the intermediate ports of Coquimbo, Copiapo, Arica, Callao, Truxillo, &c., from all which they probably receive supplies of bark in exchange for the mercury, piece-goods, flour, &c., which constitute their outward cargo.

The persons who collect the bark are called in South America *Cascarileros*. Considerable experience and judgment are requisite to render an individual well qualified for this business. He must not only be able to distinguish the trees which produce good bark from those less esteemed, but must also know the proper season and the age at which a branch should be decorticated, and the marks by which the efficiency or inefficiency of any particular product is indicated. The bark gatherers begin their operations with the setting in of the dry season, in May. Sometimes they first cut down the tree, and afterwards strip off the bark from the branches; in other instances, they decorticate the tree while standing. The former plan is said to be the most economical; as, when the tree is cut down, the stump pushes up shoots which in course of time become fit for decortication, while, if deprived of its bark, the whole plant perishes. The operator separates the bark by making a longitudinal incision with a sharp knife through its whole thickness, and then forcing it off from the branch with the back of the instrument. Other means are resorted to when the trunk or larger limbs are decorticated. According to Pöppig, the bark is not separated until three or four days after the tree is felled. It must then be speedily dried, as otherwise it becomes deteriorated. For this purpose it is taken out of the woods into the vicinity of some inhabited place, where it is exposed to the sun. In the drying process it rolls itself up, or in technical language becomes quilled, and the degree to which this effect takes place, is proportionate directly to the thinness of the bark, and inversely to the age of the branch from which it was derived. In packing the bark for exportation, due care is seldom taken to assort the varieties according either to the species of Cinchona by which they are furnished, or to their resemblance in appearance and character; and it often happens that several different kinds are introduced into the same case. The packages are, in commercial language, called *seroons*. As found in this market they are usually covered with a case of thick and stiff ox-hide, which is lined within by a very coarse cloth, apparently woven out of some kind of grass.

The Cinchona forests, being in very thinly inhabited districts, do not, for the most part, belong to individuals, and are open to the enterprise of all who choose to engage in the collection of the bark. The consequence is, that the operations are carried on without reference to the future condition of this important interest, and the most wasteful modes of proceeding are adopted if they save present trouble, or contribute to immediate profit. Some fears are entertained that the sources of this most valuable drug may in time become exhausted, and the government of Bolivia considered it necessary to enact a law, prohibiting the cutting of bark within its limits for five years

from the commencement of 1838. The law, however, has probably not been very rigidly enforced; as there has been in the market no extraordinary deficiency of Calisaya bark, which is the variety collected in Bolivia. Indeed, the great extent to which the *Cinchona* forests prevail, spreading, as they do, with some interruptions, over more than thirty degrees of latitude, and prevailing in regions which can never be applied to agricultural purposes, almost precludes the idea of their even remote extinction.

Classification.

To form a correct and lucid system of classification is the most difficult part of the subject of bark, which is throughout full of perplexities. An arrangement founded on the botanical species, though the most scientific and satisfactory when attainable, is in the present instance utterly out of the question. There are few varieties, of the precise origin of which we can be said to have any certain knowledge; by far the greater number being either derived from an unknown source, or but obscurely traceable to the species producing them.

The Spanish merchants adopted a classification dependent partly on the place of growth or shipment, and partly on the inherent properties, or supposed relative value of the bark. So long as the sources of the drug were very confined, and the number of varieties small, this plan answered the purposes of trade; but at present it is altogether inadequate; and, though some of the names originally conferred upon this principle are still retained, they have ceased to be expressive of the truth, and are often erroneously, almost always confusedly applied. The *Loxa* barks embrace, among us, not only those which come from that province, but those also from the neighbourhood of *Huanuco*; while others, which have received different names, are brought from the same place. It is said that, by the traders in South America, the young slender gray barks are called by the name of *Loxa*, from whatever source they may be derived; while those somewhat larger and older receive their appellation from Lima.

Perhaps the best arrangement for pharmaceutical and medicinal purposes is that adopted in the United States Pharmacopœia, founded upon difference of colour. It is true that dependence cannot be placed upon this property alone; as barks of a similar colour have been found to possess very different virtues; and between the various colours considered characteristic, there is an insensible gradation of shade, so that it is not always possible to decide where one ends and the other begins. Still it has been found that the most valuable barks, which are brought almost exclusively from the western or Pacific coast of South America, and are recognised only as coming from this source by our Pharmacopœia, may be arranged, according to their colour, in three divisions, which, though mingling at their extremes, are very distinctly characterized, in certain specimens, by peculiarity not only in colour, but also in other sensible properties, and even in chemical constitution. The three divisions alluded to are the *pale*, the *yellow*, and the *red*. These may be considered as exclusively the officinal barks; while the inferior varieties which approach one or other of these classes in colour, but differ in other properties, may be treated as extra-officinal, and considered under a separate head. As these inferior kinds come chiefly if not exclusively from the northern ports of New Granada and Venezuela, they are known in commerce by the name of Carthagena barks, and by this name will be described in the present work. Parcels of little value may be occasionally imported from the Pacific coast of South America; but the quantity

is small, as the profit they would yield would not pay the expense of so long a voyage. In describing, therefore, the different kinds of bark, we shall treat *first* of the officinal varieties under the three heads of *pale*, *yellow*, and *red*, and secondly of the extra-officinal under the title of *Carthagena barks*. The commercial name will at the same time be given in all instances in which a knowledge of it can be useful in this country. It is proper here to state, that the different barks frequently come to us mingled in the same package, and that, in deciding upon the character of a seroon, the druggist is guided rather by the predominance than the exclusive existence of certain distinctive properties.

There is a remarkable difference in the epidermis or outer covering of the strictly officinal barks from the western coast of South America, and that of the extra-officinal or Cathagena barks, from the ports of the Caribbean sea. In the former, the epidermis is cracked, rugose, and of a brownish colour, and, when apparently whitish, is so in consequence of adhering lichens, upon the removal of which by scraping the normal colour appears; in the latter, it is comparatively destitute of fissures, smooth, whitish or yellowish-white, and micaceous.

1. PALE BARK.

The epithet *pale* applied to these barks is derived from the colour of the powder. The French call them *quinquinas gris*, or gray barks, from the colour of the epidermis. They come into the market in cylindrical pieces of variable length, from a few inches to a foot and a half, sometimes singly, sometimes doubly quilled, from two lines to an inch in diameter, and from half a line to two or three lines in thickness. The finest kinds are about the size of a goosequill. Their exterior surface is usually more or less rough, marked with circular and sometimes with longitudinal fissures, and of a grayish colour, owing to the lichens which cover the epidermis. The shade is different in different samples. Sometimes it is a light gray, approaching to white, sometimes dull and brown, sometimes a grayish-fawn, and frequently diversified by the intermixture of the proper colour of the epidermis with that of the patches of lichens attached to it. The interior surface, in the finer kinds, is smooth; in the coarser it is occasionally rough and somewhat ligneous. Its colour is uniformly a brownish-orange, sometimes inclining to red, sometimes to yellow, and in some inferior specimens is of a dusky hue. The fracture is usually clear, with some short filaments on the internal part only. In the coarser barks it is more fibrous. The colour of the powder is a pale fawn, which is of a deeper hue in the inferior kinds. The taste is moderately bitter and somewhat astringent, without being disagreeable or nauseous. Authors speak also of an acidulous and aromatic flavour, which is less evident. The superior kinds have a feeble odour, which is distinct and agreeably aromatic in the powder and decoction. The pale barks are chemically characterized by containing a *much larger proportion of cinchonia than of quinia*; and their infusion does not yield a precipitate with solution of sulphate of soda. Their appearance indicates that they were derived from the smaller branches. They are collected in the provinces about Loxa, or in the country which surrounds the city of Huanuco to the north-east of Lima, and are probably derived chiefly from the *C. Condaminea* and *C. micrantha*.

There are several commercial varieties of pale bark, obtained from different sources, and differing more or less in their properties. The most highly esteemed of these is the *Loxa bark*, the finest specimens of which are sometimes called *crown bark of Loxa*, from the impression that they have the same origin and character with the bark formerly selected with

great care for the use of the king of Spain and the royal family. The pale bark collected about Huanuco is either named *Lima bark*, because taken to that city for commercial distribution, or *Huanuco bark*, from its place of collection. The former name has been more common in this country, where, indeed, this commercial variety has not unfrequently been confounded with the Loxa bark. Other pale barks are the *Jaen* and *Huamilies barks*, which are scarcely known as distinct varieties in the United States.*

* Since the publication of the first edition of this Dispensatory, we have had an opportunity of examining Von Bergen's splendid work upon bark, entitled *Versuch einer Monographie der China*, published in Hamburg in the year 1826. His descriptions are undoubtedly among the most precise and accurate which have been published, and we have availed ourselves of them in drawing up the following sketch of the varieties which may be arranged under the head of *pale bark*. We have also consulted, in relation to this subject, the works of the French pharmaceutical writers, particularly that of Guibourt, and the elaborate German work of Geiger, entitled *Handbuch der Pharmacie, &c.*, and, since the last edition of this Dispensatory, the more recent English treatise on *Materia Medica* by Pereira. We have thrown our remarks into the form of a note; as the information in relation to these different varieties can be of little practical use to the student, though it may possibly serve to aid the discrimination of the druggist in the purchase of bark, by enabling him to decide on the relative value of the different parcels submitted to his notice.

1. *Loxa Bark. Crown Bark.*—*Quinquina de Loxa*, Fr.—*Loxa-China, Kron-China*, Germ.—This is in cylindrical tubes, strongly rolled, from six to fifteen inches long, from two lines to an inch in diameter, and from half a line to two lines thick. The outer surface is more or less rough, seldom much wrinkled longitudinally, but marked with numerous transverse fissures, which usually run round the bark, and divide it into rings, the edges of which are somewhat elevated. In the smallest quills these fissures are not very obvious; in the larger, they are distant and apt to be interrupted. In the largest the surface is sometimes very rough and even warty. The proper colour of the epidermis is dark-gray, sometimes almost black, sometimes ash-coloured, and occasionally inclining to fawn; but frequently diversified by whitish lichens, which are in some instances so numerous as to cover almost the whole exterior of the bark, and give it a light-gray appearance. The inner surface is smooth and uniform, and of the colour of cinnamon, with occasionally a reddish tinge. The fracture in the smaller quills is quite smooth, in the larger somewhat fibrous. The bark is of a rather firm consistence, and when cut transversely exhibits a resinous character. Its odour is compared by Guibourt to that perceived in damp woods, by Von Bergen to that of tan. Its taste is acidulous, astringent, and bitterish. The powder is of a dull cinnamon colour. This variety of bark appears to contain, on an average of several results stated by Geiger, about 0.48 per cent. of cinchonina, and 0.06 of quinia. In the thicker pieces, which appear to be richest in the organic alkalies, Thiel found 1.0 per cent. of cinchonina, and 0.03 of quinia. According to Soubeiran, one pound of Loxa bark yields from a drachm and a half to two drachms of sulphate of cinchonina. The strong reaction of a solution of gelatin indicates the presence of much tannin. Guibourt, in the edition of his *Histoire des Drogues* printed in 1836, describes several varieties of Loxa bark, one answering to the above, under the name of *Quinquina gris brun de Loxa*, a second, under that of *quinquina de Loxa cendré*, which he considers identical with the Jaen bark of Von Bergen, and two others both of which he calls *quinquina de Loxa fibreux*. Of these two, one is probably not found in commerce, and the other is the variety described in his former edition as the *Quinquina gris de Loxa*. This is characterized by its light-gray colour externally, and by its extreme thinness, which is observable even in the pieces taken from the larger branches, the bark being almost as thin and as much rolled as Ceylon cinnamon. It is very rare. In the seroons of Loxa bark other kinds are sometimes mixed with the genuine. Among them are quills of a bark supposed to be identical with the Huamilies, (see *Huamilies bark*.) and a variety which has been called *white Loxa bark*, of unknown origin, resembling the genuine except in the character of its epidermis, which is whitish and micaceous like that of the Carthagena barks. English druggists distinguish Loxa bark into 1. the *picked crown bark*, which consists of the finest, thinnest, and longest quills; 2. the *silvery crown bark*, somewhat larger in size, and characterized by a whitish silvery appearance of the epidermis derived from adhering lichens; and 3. the *leopard crown bark*, named from its speckled appearance, depending on whitish lichens alternating with the dark brown epidermis. Loxa bark is thought to be derived chiefly from the *C. Condaminea*, and to have been the variety first imported into Europe.

In this country, the pale bark has fallen into disuse; and the sales made by the druggists are very small. As it yields little *quinia*, it is not employed in the manufacture of the sulphate of that alkali, which has almost superseded the bark as a remedy in intermittents; and the red bark is preferred by phy-

2. *Lima or Huanuco bark. Cinchona Cinerea, Gray bark, Silver bark, Ed.—Quinquina de Lima, Fr.—China Huanuco, Graue China, Germ.*—The Lima or Huanuco bark was introduced into notice about the year 1779, after the discovery of Cinchona trees in the central regions of Peru; but Pöppig says that the trade in it began in 1785. The first name originated from the circumstance that the bark entered into commerce through the city of Lima, the second was derived from the name of the city (Huanuco or Guanuco), in the more immediate neighbourhood of which the trees were found. The dimensions of this variety of bark do not materially differ from those of the preceding, although in the largest pieces the diameter is somewhat greater. Many of the smaller quills have a more or less spiral form. At the edge of most of the complete quills, a sharp oblique slit made with a knife is observable. The epidermis is usually adherent. The exterior surface is marked with longitudinal wrinkles, which in the thick pieces are often so deep as to amount to furrows, penetrating quite through the outer coating of the bark. Transverse fissures are also generally observable, but they never run wholly round the quill, often not more than a quarter or half round, and do not exhibit elevated borders. In some pieces the outer layer of the epidermis is rubbed off either wholly or in spots, and in a few the entire thickness of the external layers, which we usually denominate the epidermis, is here and there removed, exhibiting the proper bark in patches. The colour externally is very light gray, almost milk-white, with occasionally bluish-gray and darkish spots intermingled. Where the outer crust which imparts this whitish colour is wanting, the surface is grayish-fawn or reddish-gray, and in the thicker pieces of a dark cinnamon colour. The inner surface, though in the smaller quills sometimes tolerably uniform, is generally more or less uneven, fibrous, or splintery, especially in the larger pieces, in which may often be observed adhering yellowish-white splinters of wood. The colour is usually a rusty-brown inclining somewhat to red, with occasionally a purplish tinge. The transverse fracture is smooth in the exterior part, fibrous or splintery in the interior. The longitudinal fracture is usually somewhat uneven, without being splintery, and exhibits here and there minute shining spots. The inner layers of the bark are usually soft and friable. The colour of the powder is a full cinnamon-brown. The odour of the bark is like that of clay, and in this respect different from that of all other varieties. The taste is at first acidulous, astringent, and slightly aromatic, and ultimately bitter and adhesive. The proportion of *cinchonina* contained in Huanuco bark, by an average of several results stated by Geiger, is 1.72 per cent., of *quinia* 0.29 per cent. Von Santen got from the best specimens, as the maximum, 2.73 per cent. of cinchonina and no quinia. The most productive pieces are those of middling size. Guibourt makes two varieties of this bark, the *quinquina gris fin de Lima*, including the smaller quills, and the *quinquina gros Lima, or Lima blanc*, including the larger. It has been raised to the rank of a distinct officinal variety by the Edinburgh College. Little, if any of it, is brought to this country; and, according to Pöppig, the trade in it ceased in South America in 1815. This variety of bark is now confidently ascribed to the *C. micrantha*. (See *C. micrantha*.)

3. *Jaen bark. Ash-bark.—China Jaen, Blasse Ten-China, Germ.—Quinquina de Loxa cendré of Guibourt.* This variety probably derives its name from the province of Jaen de Bracomoros, in the vicinity of Loxa, where large quantities of bark have been collected. The Jaen bark is always in quills, which do not differ much in size from those of the Loxa bark, but are distinguishable by being frequently curved longitudinally, or bent in different directions, and somewhat spiral. The outer coat is often partially or entirely rubbed off, leaving the surface smooth and soft to the touch. When the epidermis is perfect, it exhibits small irregular transverse fissures, with occasionally faint longitudinal fissures and wavy wrinkles, and here and there a few warts, but no deep furrows. The colour varies from light or ash-gray to light yellow, diversified with blackish and brownish spots. When the outer coat is rubbed off, it inclines still more to yellow. Considered in mass, the bark always appears somewhat yellowish or straw-coloured. The exterior layers are soft and rather spongy, and may be readily scraped by the nail. The inner surface is exceedingly diversified, sometimes smooth, sometimes uneven and splintery. It is usually of a dull cinnamon colour. The bark is very brittle, and the fracture is smooth in the smaller quills, more or less uneven, and sometimes splintery in the larger, and in neither exhibits a resinous appearance. The odour is somewhat sweetish, and is compared to that of tan. The taste is acidulous, slightly astringent, and bitter without being disagreeable. The colour of the powder is cinnamon-brown. This bark is very

sicians, when it is necessary to resort to the medicine in substance. There is little doubt, however, that *cinchonia* possesses febrifuge properties little if at all inferior to those of *quinia*; and should the source of the latter begin to fail, the pale bark would come into more extensive use for the preparation of the former.

2. YELLOW BARK.

The official term yellow bark should be considered as applicable only to the valuable variety of the drug having this colour. This is known in commerce under the name of *Calisaya*, which has been said, though erroneously, to be derived from a district of country in Bolivia, near the city of La Paz, where the bark is collected.* Among the druggists, the *Calisaya*

deficient in alkalies. Some experimenters have found none, or only traces, while the highest product obtained was 80 grains of quinia and 13 grains of cinchonia from a pound. It is, therefore, without value. Von Bergen believes it to be the product of the *C. ovata* of the Fl. Peruv. It is exported from South America chiefly in chests.

Von Bergen describes another variety of pale bark, under the name of *dark Jaen bark* (*dunkle Ten-China*), or *pseudo Loxa*, which bears a considerable resemblance to the genuine *Loxa*, but may be distinguished by the oblique or bent shape of the quills, and the uneven, fibrous, or even splintery appearance of the inner surface. It seldom comes in large pieces. It contains very little of the active principles of bark. Von Santen discovered neither quinia nor cinchonia in two specimens which he examined. Its general appearance, and strong reaction with a solution of gelatin, appear to associate it with the *Loxa* bark; and Geiger's conjecture is not improbable, that it is the product of the same tree growing in unfavourable situations, or altered by disease.

4. *Huamilies bark*.—*China Huamilies*, Germ.—This bark is not generally known as a distinct variety, though probably identical with the *quinquina ferrugineux*, or ferruginous bark of the French writers. Its commercial name was undoubtedly derived from the province of Huamilies, which lies in the interior of Peru, to the northward of Huanuco, and is a part of the country explored by the botanical expedition under Ruiz and Pavon. It came into notice in Germany about the beginning of the present century, when a parcel of it was imported directly from Lima into Hamburg. It is in quills and flat pieces. The quills are from three lines to an inch and a half in diameter, from five to sixteen inches long, and from half a line to three lines thick. The flat pieces, which are usually only fragments of the largest quills, are from one to two inches broad, and six to twelve inches long. In general all the layers of the bark are present, but sometimes the outer coat, and even the whole of that part usually called the epidermis in our descriptions of bark, (including those outer layers which in the tree are destitute of vitality, having been thrown outward by the annually renewed layers beneath them,) are wanting in spots, though very seldom entirely absent. The epidermis is comparatively thin, very brittle, soft, and spongy. The outer surface, in the small and middling quills, is sometimes nearly smooth, but usually marked with wavy longitudinal wrinkles, and beset here and there with warts. These warts are abundant upon the thick pieces, which they sometimes almost entirely cover. Transverse fissures are seldom found, and only in the thick pieces. The colour of the epidermis is usually grayish-fawn, here and there passing into a rusty brown; but in the thicker pieces, in which the warts are abundant, it is between a liver and chestnut colour, often mixed with a tinge of purple. When the epidermis is wanting, the colour is often a full ochre yellow. The inner surface is sometimes uniform and almost smooth, sometimes slightly fibrous, rarely splintery. The colour of the surface is rusty brown, occasionally reddish, and in the fibrous or splintery pieces of an ochre yellow. The fracture in the smaller quills is rather even, in the larger presents short fibres, and is sometimes even splintery. The odour of the bark is feeble but agreeable, the taste somewhat aromatic, bitterish, and slightly astringent. The powder is of a full cinnamon colour. The average product of cinchonia and quinia, as stated by Geiger, is 0.67 per cent. of the former, and 0.25 of the latter; so that the bark, though dissimilar in appearance from the other varieties of pale bark, agrees with them in containing more cinchonia than quinia. Von Santen obtained, as a maximum, 1.2 per cent. of cinchonia, and little or no quinia. Huamilies bark is now believed to be the product of the *C. purpurea* of the *Flor. Peruv.* (See *C. pubescens*.) It is scarcely known in the United States. (*Note to Second Edition, altered in the fourth and fifth.*)

* No such province exists in Bolivia. According to M. Laubert, the name is a corruption of *calisalla*, said to be derived from *colla*, a remedy, and *salla*, a rocky country. (*Journ. de Pharm.* xxii. 614.)

bark is arranged in two divisions, the quilled and the flat, which sometimes come mixed together in the same seroon, sometimes separate. The appearance of both indicates that they were taken from larger and older branches than those which yield the pale varieties. They are sometimes called by the French *quinquina juane royal*, from their resemblance to a variety of bark formerly collected for the Spanish king.

The *quilled Calisaya* (*Calisaya arrolada* of the Spanish Americans) is in pieces from three or four inches to a foot and a half long, from a quarter of an inch to two or three inches in diameter, and of equally variable thickness. The epidermis is of a brownish colour diversified or concealed by whitish or yellowish lichens, is marked by longitudinal wrinkles and transverse fissures, and is often partially separated, and generally easily separable from the proper bark. In the larger kinds it is thick, rough, deeply indented by the transverse fissures which often surround the quills, and is composed of several layers separated from each other by a reddish-brown membrane like velvet. The epidermis yields a dark-red powder, is tasteless, and possesses none of the virtues of the bark. It is desirable, therefore, to get rid of it before the bark is powdered, as the medicine is thus procured of greater strength. The bark itself, without the epidermis, is from one to two lines in thickness, of a fibrous texture, and when broken presents shining points, apparently the termination of small fibres running longitudinally, which, examined by the microscope, are found, when freed from a salmon-coloured powder that surrounds them, to be yellow and transparent. They readily separate when the bark is powdered, in the form of spiculæ, which, like those of the cowhage, insinuate themselves into the skin, and produce a disagreeable itching and irritation. The colour of the bark is brownish-yellow with a tinge of orange, the taste less astringent than that of the pale bark, but much more bitter; and the bitterness is somewhat peculiar. The external part of the proper bark is more bitter and astringent, and consequently stronger in medicinal power, than the internal; probably from the longer exposure of the latter to the action of air and moisture. The odour is faint, but when the bark is boiled resembles that of the pale varieties. The small quills closely resemble some of the pale varieties in appearance, but may be distinguished by their very bitter taste.

The *flat Calisaya* (*Calisaya plancha* of the Spaniards) which appears to have been derived from the large branches and trunk, is in pieces of various lengths, either quite flat, or but slightly curved, generally destitute of the epidermis, and therefore presenting the yellowish colour of the bark both within and without. It is usually thicker than the quilled, more fibrous in its texture, less compact, less bitter, and possessed of less medicinal power. Though weaker than the proper bark of the quills, it is usually, in equal weight, more valuable than that variety, because free from the useless epidermis.

The valuable yellow bark is characterized by its strongly bitter taste, with comparatively little astringency; by its fine brownish-yellow somewhat orange colour, which is still brighter in the powder; and by *containing a large proportion of quinia with very little cinchonina*. The salts of quinia and lime are so abundant in its composition, that its infusion instantly precipitates a solution of sulphate of soda. (*Guibourt*.)*

* The Calisaya bark is the third variety of Von Bergen, who describes it under the name of *China Regia* or *König's China*. We give a brief abstract of his description, omitting the form and dimensions, which are given with sufficient minuteness in the

Nothing is known with certainty as to the particular species which yields *Calisaya* bark. Some writers, influenced simply by its official title of yellow bark, have attributed it to the *C. cordifolia*; because Mutis gave the same name to the product of this species. The British Colleges fell into this error,

text. The epidermis,† which in many of the small quills is partly wanting, in the flat pieces usually altogether absent, is very thick and brittle, constituting from a third to one-half of the bark, and in some of the largest quills, or partially quilled pieces, even two-thirds. In the latter case it may often be seen to consist of six or eight different layers. The quills are generally marked with longitudinal wrinkles and furrows, as well as with transverse fissures, the last of which are never absent. The fissures, which often form complete circles round the quills, have usually an elevated border, and sink so deeply in many of the larger pieces, that they are even observable upon the proper bark. In the smaller pieces, they are often faint, but usually crowded. The colour of the epidermis varies from whitish-gray to bluish-gray, but is very much diversified by lichens, so as to present yellowish-white, ash-gray, and blackish spots. When the outer layer of the epidermis is wanting, as is not unfrequently the case to a greater or less extent, the colour is somewhat sooty-brown, or almost liver-brown. The outer surface of the pieces without epidermis, is of a colour between cinnamon-brown and dark rusty-brown. The inner surface, in the pieces of all dimensions, is uniform and almost smooth, but exhibits fine longitudinal fibres closely compressed. Splinters of wood are never found adhering to the inner surface, as in some other varieties. The prevailing colour of this surface is mostly a rather dark or full cinnamon-brown, passing sometimes into a rusty-brown, but seldom of a reddish hue. This bark breaks more easily in the longitudinal direction than any other variety, exhibiting a chestnut-brown colour in the part answering to the epidermis, a more or less dark cinnamon-brown in that answering to the proper bark. The transverse fracture of the epidermis is rather even, that of the inner part sometimes fibrous, sometimes splintery. A resinous layer may be observed beneath the epidermis, which usually remains when the latter is removed, and communicates to the flat pieces the dark colour by which their external surface is distinguished. Small sharp splinters, which in the longitudinal fracture appear like shining points, are apt to insinuate themselves into the skin, when the bark is broken or much handled. The odour is feebly tan-like, the taste slightly acidulous, strongly but not disagreeably bitter, somewhat aromatic, feebly astringent, and rather durable. The powder is of a fine cinnamon hue.

Thiel obtained from the flat *Calisaya* bark 2·3 per cent. of quinia, and 0·08 of cinchonia; *Michaelis* from the flat 3·7 per cent., and from the quill 2·0 per cent. of quinia, but no cinchonia from either; *Von Santen* from the flat, an average of 2·0 per cent. of quinia, and little or no cinchonia; *Wittstock*, on an average, 3·0 per cent of sulphate of quinia, and 0·12 of cinchonia. (*Geiger*.)

Under the name of *light Calisaya*, *Guibourt*, in the last edition of his work, describes a variety of bark which he says is brought from the same region of country that produces the genuine. It is identical with that named in previous editions orange-yellow bark (*quinquina jaune orangé*), and is of comparatively little value, at least for the preparation of sulphate of quinia, though the best specimens, as they contain much cinchonia, are not without medicinal activity. Like the *Calisaya*, it is in quills or flat pieces, sometimes with and sometimes without the epidermis; but it may be distinguished by its want of thickness, its finer and more compact texture, and by a character which is most striking in the fresh specimens, viz., that of presenting a rose colour in the part which is near the epidermis, while the inner portion is of a pure yellow, so that the whole bark has an orange colour. The epidermis, moreover, when present, is thin, smoother than that of the genuine *Calisaya*, and without the numerous transverse fissures which mark the latter bark.

Another bark derived from the same region of country as the preceding, and sometimes sold as *Calisaya* bark, though wholly without quinia, is described by *Guibourt* under the name of *Cusco bark*, and has recently attracted some attention as the source of a new alkali discovered by *MM. Pelletier* and *Coriol*, and named *aricina* from the port of *Arica*, whence the bark is said to be sent. The smaller pieces may be distinguished from the genuine *Calisaya* by their white, uniform epidermis, without fissures; but when the epidermis is wanting, as frequently happens in the larger pieces, the two barks might easily be confounded. The test of sulphate of soda may here be found useful; as this

† By the epidermis is here understood the whole of the external layers which are accumulated upon the outer surface of the bark by the annual renewal of the cortical layers, and the consequent separation of those of former years, which remain, but without life, attached to the external surface. A different meaning is attached to the term by *Von Bergen*, but as we have taken pains to make the description in every instance correspond with our definition, we do not misrepresent his meaning.

without, however, being aware that the yellow bark which they adopted as officinal, was really the *Calisaya*. That it is an error has been fully demonstrated; as no *Calisaya bark* is brought from those regions where the *C. cordifolia* most abounds. In the last edition of the Edinburgh Pharmacopœia, the error has been corrected. Many writers ascribe this variety to the *C. lancifolia*, on the authority of Mutis himself, who asserts that it is indisputably derived from that species. But Mutis was mistaken; for it is now well known, that the bark of the *C. lancifolia* is wholly different from the *Calisaya*. (See *C. lancifolia*.) Ruiz was disposed to ascribe it to his *C. lanceolata*; but Von Bergen found a specimen of the bark of this species in Ruiz's collection to be different from the officinal yellow bark. According to M. Auguste Delondre, who received specimens of the plants producing *Calisaya bark* from his correspondents in South America, no less than three distinct trees contribute to furnish the bark thrown into commerce under that title. One of these specimens appeared to Guibourt to belong to the *Cinchona micrantha*, and another to the *C. Condaminea*. The third resembled the latter of these two species, but differed somewhat both in its leaves and fruit. A fourth specimen had fruit like that of the *Condaminea*, but smaller leaves, and was considered by Guibourt as probably the *C. angustifolia* of Ruiz, now thought to be merely a variety of the *C. lancifolia*. But this information is quite too vague to lead to any satisfactory conclusion. It may, however, serve to explain the fact that barks are sometimes imported under the name of *Calisaya*, and derived from the same district of country, which differ from the genuine bark both in appearance and qualities, and will not serve for the preparation of sulphate of quinia.*

The genuine *Calisaya bark* is produced most abundantly, if not exclusively, in Bolivia, formerly Upper Peru, in the province of La Paz and in the country about Apolobamba on the Rio Paro; and, before the disturbances in these countries, was shipped as well from the port of Buenos Ayres as from those on the Pacific. It is at present, however, procured exclusively from the latter. A very fine parcel was exhibited to us, imported directly from Coquimbo in Chili. We have been informed by gentlemen who have been long personally engaged in commercial transactions upon the Pacific coast of South America, that the *Calisaya bark* of commerce is originally obtained chiefly, if not exclusively, at the port of Arica, whither it is brought from the interior provinces of Bolivia. From that town it is sent to various other ports on the Pacific. It is generally supposed to have been first introduced into commerce towards the end of the last century, and it was probably not known by its present name till that period; but La Condamine states that the Jesuits of La Paz, at a period anterior to the discovery of the febrifuge of Loxa, sent to Rome a very bitter bark by the name of *quinaquina*, which, though supposed by that traveller to have been derived from the Peruvian balsam tree, was very probably, as conjectured by Guibourt, the true cinchona. Besides, Pomet, in his *History of Drugs*, published in 1694, speaks of a bark more bitter than that of Loxa, obtained from the province of Potosi, which borders upon that of La Paz; and Chomel

salt, which so strikingly precipitates the infusion of *Calisaya*, does not disturb that of the Cusco bark. It is proper to state, that Guibourt could obtain from this bark no other alkali than cinchonia, and is disposed to consider aricina as the result of the modifying influence of the process employed in its preparation. (*Note to the Second and Fourth Editions*.)

* See Guibourt's *Histoire des Drogues*, 1836, and an interesting article upon the subject of the origin and collection of the *Calisaya bark*, in the *Journal de Pharmacie*, xxi. 505, and in the *American Journ. of Pharm.*, vii. 325.

also states that the cinchona tree inhabited the mountains of Potosi, and produced a bark more esteemed than that which grew in the province of Quito. (*Guibourt, Journ. de Pharm.* xvi. 235.) It is possible that, though known at this early period, it may have gone out of use; and its re-introduction into notice towards the end of the last century, may have been mistaken for an original discovery. Whether it is found in the other localities of bark in Peru and Quito, it is difficult to determine; but we may infer from the existence of a commercial variety known to the Spaniards by the name of *Calisaya de Quito*, that either the identical bark, or a variety closely analogous to it, has been found in that province. The *Calisaya de Santa Fé*, mentioned by Laubert, has no other claim to the title given it than its colour; and it is not distinguished in the market, perhaps not distinguishable from the ordinary yellow Carthagena bark.

3. RED BARK.

The name of this variety is very appropriately applied; as the colour is usually distinct both in the bark and the powder. In South America it is called *cascarilla roxa* and *colorada*. Some writers have divided it into several sub-varieties; but there does not seem to be ground for such division in any essential difference of properties. Like the *Calisaya*, it comes in quills and flat pieces, which are probably derived from different parts of the same tree. It is imported in chests.

Some of the pieces are entirely rolled, some partially so, as if they had been taken from half the circumference of the branch; others are nearly or quite flat. They vary very greatly in size, the quill being sometimes less than half an inch in diameter, sometimes so much as two inches, while the flat pieces are occasionally very large and thick, as if derived from the trunk of a tree. They are covered with a reddish-brown or gray, sometimes whitish epidermis, which is rugged, wrinkled longitudinally, and in the thicker pieces marked with furrows, which in some places penetrate to the surface of the proper bark. In many specimens, numerous small roundish or oblong eminences, called warts, may be observed upon the outer surface. Beneath the epidermis is a layer, dark red, brittle, and compact, which possesses some bitterness and astringency, but much less than the interior parts. These are woody and fibrous, of a more or less lively brownish-red colour, which is usually very distinct, but in some specimens passes into the orange and even yellowish-brown; so that it is not always possible to distinguish the variety by this property alone. The taste is bitter and astringent, and the odour similar to that of other good barks. Red bark is chemically distinguished by *containing considerable quantities both of quinia and of cinchonia*.* It yields a turbid salmon-coloured decoction with water.

* The red bark is given as a distinct variety by Von Bergen, and stands first on his list, under the name of *China rubra* or *rothe China*. The following is an abstract of his description.

The quills are from two lines to an inch and a quarter in diameter, from one-third of a line to two lines thick, and from two to twelve inches or more in length. The smaller quills are often spiral. The flat pieces are from one to two inches broad, from three-eighths to a quarter of an inch thick, and of the same length as the quills. In the smaller and middling-sized quills, the external surface exhibits longitudinal wavy wrinkles. In the thicker pieces, these wrinkles, between which are here and there longitudinal furrows, often elevate themselves into roundish or oblong warts, which are of a somewhat friable and granular consistence. The longitudinal furrows sometimes penetrate to the bark. Transverse fissures seldom occur. The colour in the smaller quills varies from a fawn-gray to a dull reddish-brown, in the larger is reddish-brown or chestnut-brown with a tinge of purple. When the wrinkles and warts are rubbed off, the peculiar brownish-red

The species of *Cinchona* which produces red bark is unknown—the notion derived from Mutis, and formerly generally prevalent, that it was obtained from the *C. oblongifolia* of that botanist, having been demonstrated to be incorrect. For the proofs upon this point, which have now ceased to have any practical importance, the reader is referred to the article CINCHONA, section RED BARK, in former editions of this work. It has been supposed that red bark may be derived from the same species with one or more of the pale barks, but taken from the larger branches or the trunk. This opinion receives some support from a statement made by La Condamine, in his memoir upon the subject of cinchona. We are told by this author that three kinds of bark were known in the neighbourhood of Loxa—the white, the yellow, and the red. The white, so named from the colour of the epidermis, scarcely possessed any medicinal virtue, and was obtained from a tree entirely distinct from that which yielded the two other varieties. The red was superior to the yellow; but he was assured, on the very best authority, that the trees producing them grew together, and were not distinguishable by the eye. Of the three varieties mentioned by La Condamine, the white, which was probably one of the inferior barks with micaceous epidermis, does not reach us; and that which he calls yellow is probably identical with the pale variety of the Pharmacopœia, as this grows most abundantly about Loxa. Should it be admitted that the red bark is furnished by the same tree which yields the pale, we have a ready explanation of the difference in size of the two varieties.

CARTHAGENA BARKS.

Under this head may be classed all the *Cinchona* barks brought from the northern Atlantic ports of South America. In commerce, they are variously

coloured the bark appears. The pieces are often in part or almost wholly covered with a whitish-gray or yellowish-white coat, either belonging to the epidermis or consisting of lichens. In some of the quills the epidermis is wanting in spots, which exhibit a dirty reddish-cinnamon colour. The inner surface is delicately fibrous and almost uniform in the small quills, but becomes more fibrous and uneven in the larger, and in the flat pieces is splintery and very irregular. Its colour varies with the size of the pieces, being a reddish-rusty brown in the least, redder in the larger, and a full brownish-red in the largest. The inner surface is also sometimes yellowish, or brownish, or of a dirty appearance. It becomes darker when scraped with the nail or other hard body. The fracture exhibits the different colours of the epidermis and inner bark, as also of a resinous layer which lies between the two. It is usually smooth in the smaller quills, fibrous in the larger, and at the same time fibrous and splintery in the largest and flat pieces. The fracture of the epidermis, however, is in all either smooth, or only here and there somewhat granular. The odour is like that of tan and earthy, the taste strongly but not disagreeably bitter, somewhat aromatic, and not lasting. The powder is of a dull brownish-red colour.

Experiments upon many different specimens of red bark, as stated by Pfaff, give as an average result 1·7 per cent. of pure cinchonia, and 0·44 of sulphate of quinia. The highest product obtained was 3·17 per cent. of cinchonia, and 0·15 of sulphate of quinia. Another specimen yielded 1·21 per cent. of the former, and 1·33 of the latter. Pelletier and Caventou obtained 0·8 per cent. of cinchonia, and 1·7 of quinia. (*Geiger.*) It appears, therefore, that the proportion of the alkalies is exceedingly different in different specimens. The degree of bitterness is, perhaps, the best criterion of their efficacy.

Guibourt divides the red bark into two varieties, which he distinguishes by the names of *quinaquina rouge verruqueux*, and *quinaquina rouge non verruqueux*, from the presence or absence of the warts upon the outer surface. He describes also a variety of bark, under the name of *quinaquina rouge de Lima*, resembling the proper red bark in appearance, but without bitterness; and two others, distinguished severally by the names of *quinaquina rouge orangé*, and *quinaquina rouge pale*, which, however, merit little attention. (*Note to Second and Fourth Editions.*)

A specimen of bark in our possession, brought by Dr. Dillard, of the U. S. Navy, from the Pacific, and labelled *red bark of Cuenca*, has a thick epidermis like that of the ordinary red barks, is of a very deep dark-red colour, and possesses little bitterness.

called *Carthagena*, *Maracaybo*, and *Santa Martha barks*, according to the particular port at which they may be shipped. They are all characterized by a soft, whitish or yellowish-white, micaceous epidermis, which may easily be scraped by the nail, and which, though often more or less completely removed, almost always leaves behind traces sufficient to indicate its character. They contain both cinchonia and quinia, though in smaller proportion than the best barks from the Pacific. It has before been stated that similar barks are found on the Western coast of South America; but they never reach us unless accidentally; as they would not bear the expense of carriage. Such are the *white barks* of the Spanish writers. The *Carthagena barks* are not recognised as officinal by the Pharmacopœias. In the state of powder, however, they are generally kept in the shops, and sold for tooth powder, &c., under the name of *common bark*. They are moreover not unfrequently substituted, either fraudulently or by mistake, for the better kinds. Like the proper officinal barks they may be arranged into several subdivisions, according to their diversities in colour.

1. *Yellow Carthagena Bark*. This is by far the most abundant of the non-officinal barks, and the only one uniformly found in the market. It occurs in quills or flat pieces, but most commonly in the latter form, and is distinguished, independently of the peculiar epidermis already described, by the brownish-yellow colour of the proper bark. There are two varieties of it very well characterized by their appearance and other properties, but not distinguished in commerce.*

* Von Bergen considers the *Carthagena barks* under the two divisions of 1. *China flava dura*, or *harte gelbe China*, and 2. *China flava fibrosa*, or *holzige gelbe China*. As these, with the varieties before noticed as described by him, complete the nine divisions under which he ranks the barks of commerce, we shall give a brief abstract of his account of them.

1. *China flava dura*, or *hard yellow bark*.—This is in quills and flat pieces. The quills are from three to eight lines in diameter, from half a line to a line and a half thick, and from five to nine inches, and sometimes, though rarely, even fifteen inches long. The flat pieces are considerably thicker, from half an inch to two inches broad, and from four to eight in length. They are often somewhat twisted, and so curved in the drying that the upper surface is rather concave. The epidermis is in many pieces partially or almost wholly wanting. The outer surface is on the whole rather smooth, though it usually exhibits a few faint longitudinal furrows and transverse fissures, and pieces are occasionally found with hard warts or protuberances. In the flat pieces, the epidermis, when present, has somewhat of the consistence of cork, and consists of several layers. The colour of the epidermis varies from yellowish-white to ash-gray, and is sometimes diversified by bluish-gray or blackish lichens. When it is wanting, the colour is between a dark cinnamon and brownish-yellow. These shades, however, are seldom clear; and the flat pieces have usually a somewhat dusty aspect. The inner surface of the quills is tolerably uniform, that of the flat pieces uneven or faintly furrowed and even splintery, the points of the splinters often projecting. Its colour, which is almost always dull, as if the surface were dusty, varies between a light cinnamon and a dull ochre-yellow, and in some pieces is rusty-brown or fawn-gray, or even whitish-yellow. The bark does not readily break in the longitudinal direction. The transverse fracture presents short splinters, and is sometimes fibrous. When cut transversely, the bark obscurely exhibits a very small darker coloured resinous layer beneath the epidermis. The odour is feeble, the taste slightly astringent and bitter, but not strongly so. The powder is of the colour of cinnamon. Von Bergen attributes this variety to the *C. cordifolia*.

2. *China flava fibrosa*, or *woody yellow bark*.—In shape and dimensions, this variety does not materially differ from the preceding; but the flatter pieces are almost always a little rolled, or curved laterally. The epidermis is seldom entire, being in general either in part or wholly rubbed off. When present, it resembles in consistence that of the former variety. Its outer surface is nearly smooth, only marked here and there with faint irregular transverse fissures and longitudinal furrows. Its colour varies from a dirty whitish-gray to yellowish, but is sometimes more or less dark. When the outer surface is rubbed off, as is the case here and there in the quills, and almost always in the flat pieces, the colour is a nearly pure ochre-yellow. Where the whole thickness of the epidermis is

Hard yellow Carthagena Bark (*China flava dura* of Von Bergen) is in pieces of various size and form, sometimes wholly or partially quilled, and sometimes flat; and the flat pieces present the appearance of having been warped in drying, being frequently curved longitudinally backward, and sometimes also in the transverse direction or spirally. The dimensions are sometimes those given by Von Bergen (*see note*); but, as found in this market, the bark is more commonly in small, irregularly square or oblong, flattish, and variously warped pieces, from one to three or four inches long and from one to three lines in thickness, mixed with small quills or fragments of quills, the former appearing as if chipped from the trunk or large branches, the latter evidently derived from the small branches. In this shape it was treated of, in former editions of this work, as a distinct variety, under the name of *Santa Martha bark*, which it at one time held in the market; but a closer examination has convinced us that it is the same bark as the *hard yellow bark* of Von Bergen, though collected in a different manner. The quills are generally more covered with the micaceous epidermis than the flat pieces, in which it is often nearly or quite removed. The inner surface of the latter, though sometimes smooth, is often rough and splintery, as if forcibly separated from the wood to which it adhered. The colour of the proper bark is a pale, dull, brownish-yellow, darker in parcels which have been long kept; and the surface often appears as if rubbed over with powdered bark. The texture is rather firm and compact, and the fracture abrupt, without being smooth or presenting long splinters. The taste is bitter and nauseous. This variety of bark is thought to be obtained from the *C. cordifolia*; as Guibourt found that a specimen of the bark of that tree, which came originally from Mutis, resembled it precisely in all its sensible properties.

Fibrous yellow Carthagena Bark (*China flava fibrosa* of Von Bergen) is said by Von Bergen and Pereira sometimes to occur in quills, but we have seen it only in flat or slightly rolled pieces, which are from half an inch to two inches broad, and from four to six or even nine inches long. It differs from the former variety chiefly in a somewhat brighter colour, and in its less compact and very fibrous texture, which causes it to exhibit long splinters when broken transversely, and often to hang together by connecting fibres when broken longitudinally. A more precise description will be found in the note below.

wanting, as happens here and there in spots, it is dark cinnamon, or dark ochre-yellow, and commonly dull or powdery. The inner surface is usually even, but is sometimes irregular and splintery, and always feels harsh to the fingers, leaving small splinters sticking in the skin when drawn over it. The colour is a nearly pure ochre-yellow, like that of the external surface when the outer layer is rubbed off, though somewhat duller and very powdery. The fracture distinguishes this variety from the preceding and from all others. The longitudinal fracture is strikingly fibrous, and in the flat pieces the fragments still hang together by connecting fibres. The bark, moreover, breaks obliquely, and the fracture even of the epidermis, which in other varieties is almost always smooth, is here uneven or rough-grained. The transverse fracture exhibits very long and thin splinters or fibres, which are very flexible, and may almost be said to be soft. No traces of a resinous appearance are observable in the fracture. The odour is feeble, the taste at first woody and flat, afterwards slightly bitter and astringent, and weaker in this than any other variety of bark. The colour of the powder is intermediate between that of cinnamon and yellow-ochre. The tree from which this variety is obtained is unknown.

Of these two varieties of Carthagena bark, the first yielded, on an average of two experiments, 0.57 per cent. of pure cinchonia, and 0.33 per cent. of sulphate of quinia; the second yielded, on an average of five trials with different specimens, 0.4 per cent. of pure cinchonia, and 0.36 of sulphate of quinia. The highest product of the woody bark was about 0.59 per cent. of cinchonia, and 0.52 of sulphate of quinia. From this statement, it appears that, so far as regards the relative proportion of their two active ingredients, they should rank with the red bark, though greatly inferior to it in strength.

We have recently seen specimens of a bark, of which large quantities were said to have been brought in a cargo from Maracaybo, presenting the general aspect, and in a striking degree the fibrous texture of this variety, but in rather larger pieces, and differing also somewhat in the colour, which, instead of being a nearly pure ochre-yellow, has an orange tint, especially in the exterior portion, where it is decidedly reddish in some of the pieces. This particular bark has a very close resemblance to the officinal yellow or Calisaya, for which it might readily be mistaken by an inexperienced person, and, if regarded only upon its inner surface, even by the most experienced. But the bark is rather thicker, less hard, compact, and heavy, and much more fibrous than the Calisaya, and, though in general deprived of the epidermis, yet occasionally exhibits remains of it, having the characters of that of the Carthagena barks, and where it is quite absent, appears as though it had been removed by scraping or cutting with a knife, and not spontaneously separated at the natural juncture, as in the Calisaya. Besides, the bark is spongy under the teeth, and wants the strong peculiar bitterness of the officinal yellow. Still it has a decidedly bitter taste, and its infusion, though not precipitated by solution of sulphate of soda, affords a copious precipitate with infusion of galls, indicating the presence of no inconsiderable proportion of the active alkaline principles.

A specimen of bark labelled *yellow bark of Loxa*, brought from South America by Dr. Dillard of the U. States Navy, and said to be employed in Loxa for making extract of bark, presents characters closely analogous to those of the fibrous Carthagena bark, and sufficient to justify the supposition that it was derived from the same species of Cinchona.

The powder of yellow Carthagena bark has a yellowish cinnamon-colour, with less of the reddish tint than the Calisaya, for which, however, it may be readily mistaken, and, there is reason to believe, is not unfrequently sold. It may be distinguished by its comparatively feeble bitterness; but much more certainly by the test of sulphate of soda, which throws down no precipitate with its infusion.

2. *Red Carthagena Bark.* This name properly belongs to a bark known to the French Pharmacutists by the name of *quinquina nova* or *new bark*, and ascertained to be Mutis's *red bark of Santa Fè*, produced by his *Cinchona oblongifolia*—the *C. magnifolia* of the Flora Peruviana. It is never found in our markets, unless sometimes, possibly, as an adulteration of the officinal red bark.* A red bark, with whitish and micaceous epidermis, thick, spongy, and of little taste, is sometimes mixed with the packages of the officinal red bark from the Pacific. May it not be the product of the same species of Cinchona, which grows in Peru as well as in New Granada?

3. *Orange Carthagena Bark.* This is the *orange cinchona* of *Santa*

* As described by Guibourt, this bark is in pieces a foot or more long, rolled when small, open, or nearly flat when larger, in general of a perfectly cylindrical form; with a whitish, thin, uniform epidermis, showing scarcely any cryptogamia, and but a few transverse fissures answering to those of the liber, and sometimes entirely wanting; one to three lines thick without the epidermis; of a pale carnation colour, becoming deeper in the air, especially upon the outer surface, which, when destitute of epidermis, is always reddish-brown; of a fracture which is foliaceous in the outer part, and short-fibrous in the inner; and exhibiting, under the microscope, between its fibres, and especially between the laminae, a great abundance of two granular matters, of which one is red and the other whitish. In some pieces the fracture exhibits, nearer the external than the internal surface, a yellow, transparent, resinous or gummy exudation. The taste is flat and astringent like that of tan, the odour feeble, between that of tan and the pale barks. The powder is fibrous and decidedly red. Examined by Pelletier and Caventou it afforded neither quinia nor cinchonina.

Fé, so highly lauded by Mutis, and the *spongy Carthagena bark* of Guibourt. It has occurred in commerce in large, flat, somewhat curved, or semicylindrical pieces, sometimes as much as three or four inches broad, a foot long, and nine lines in thickness, covered with a yellowish-white, micaceous epidermis, marked with longitudinal and sometimes transverse fissures. The bark itself is of an orange colour, externally fibrous, light, spongy under the teeth, without taste or very feebly bitter, and destitute of medical virtue. It yields a beautiful orange powder. It scarcely occurs at present in commerce. The destruction at Cadiz, by the Spanish authorities, of a large quantity of this bark, collected by Mutis at the expense of the government, which was ascribed by Humboldt to mercantile cunning, is now considered as an indication of a just appreciation of its virtues. The bark is the product of the *C. lancifolia*.

4. *Brown Carthagena Bark.* Under this name Guibourt has described a bark of a white and smooth epidermis, rough, hard, compact, very heavy, sometimes as much as half an inch in thickness, of an orange-brown colour when freshly cut, and a chocolate colour upon its inner surface, and of a bitter astringent taste analogous to that of the pale barks, but more disagreeable. Some of the pieces from the smaller branches are completely quilled, and others somewhat larger appear as if warped or contorted by desiccation. Pereira thinks this may be a variety of the *hard yellow Carthagena bark*. We have not met in this market with specimens answering the description of Guibourt.

FALSE BARKS.

Before dismissing the subject of the varieties of cinchona, it is proper to observe that numerous barks have at various times been introduced into the market, and sold as closely resembling or identical with the febrifuge of Peru, which experience has proved to differ from it materially, both in chemical composition and medicinal virtues. These barks are generally procured from trees which were formerly ranked among the Cinchonæ, but are now arranged in other genera. They are distinguished from the true Peruvian bark by the absence of quinia and cinchonina. Among them are 1. the *Caribæan bark*, from the *Exostemma Caribæa*; 2. the *St. Lucia bark*, or *quinquina piton* of the French, derived from the *Exostemma floribunda*; and 3. the *Pitaya bark*, from the mountain of Pitaya in Columbia, of uncertain botanical origin, known in France by the name of *quinquina bicolore*, and in Italy by that of *china bicolorata*. Of these the last only is known in this country. A considerable quantity of it was some time since imported into New Orleans, whence a portion reached this city. The specimen in our possession is in quills, for the most part singly, but in some instances doubly rolled, from eight or ten inches to more than two feet in length, and from a quarter of an inch to an inch or more in diameter. The outer surface is of a dull grayish-olive colour, with numerous large oval or irregular spots much lighter coloured, sometimes even whitish, and slightly depressed beneath the general surface, as if a layer of the epidermis had fallen off within their limits. It is to this appearance that the bark owes its name of *bicolorata*. The colour of the internal surface is deep brown or almost blackish; that of the fresh fracture, brownish-red or orange. The bark is hard, compact, and thin, seldom as much as a line in thickness, and breaks with a short but not smooth fracture. Its taste is very bitter and of a flavour not unlike that of some of the inferior kinds of cinchona. It is without odour. Folchi and Peretti found in it a new crystallizable alkaline principle, which they named *pitaina*. It has been considerably employed

by the Italian physicians, and Brera found it to cure intermittents in the quantity of half an ounce. (See a paper by Dr. Carson in the *Am. Journ. of Pharm.* xiii. 49.)

Chemical History.

In the analysis of Peruvian bark, the attention of chemists was at first directed exclusively to the action of water and alcohol upon it, and to the determination of the relative proportion of its gummy or extractive and resinous matter. The presence of tannin and of various alkaline or earthy salts in minute quantities was afterwards demonstrated. Fourcroy made an elaborate analysis, which attracted much attention at the time, and proved the existence of other principles in the bark than those previously ascertained; but the results which he obtained were not very definite. Dr. Westring was the first who attempted the discovery of an active principle in the bark, on which its febrifuge virtues might depend; but he was unable to carry out his conception to any successful result. Seguin afterwards pursued the same track, and endeavoured, by observing the effects of various re-agents, to discover the relative value of different varieties of the drug. The conclusions, however, at which he arrived, have not been supported by subsequent experiment. M. Deschamps, an apothecary of Lyons, obtained from bark a crystallizable salt of lime, the acid of which Vauquelin afterwards separated, and called *kinic acid*. The latter chemist also pushed to a much further extent the researches of Seguin, as to the influence of re-agents. He examined seventeen different kinds of bark, which he arranged in three classes, according to their chemical relation with certain re-agents—the *first* class including those which afforded precipitates with tannin and not with gelatin; the *second*, those which precipitated gelatin and not tannin; the *third*, those which precipitated at the same time tannin, gelatin, and tartar emetic. He supposed those to be the most efficient which gave precipitates with tannin or the infusion of galls; but his classification has been abandoned with the progress of discovery. Reuss of Moscow succeeded in isolating a peculiar colouring matter from red bark, which he designated by the name of *cinchonic red*, and obtained a bitter substance, which probably consisted in part of the peculiar alkaline principles, subsequently discovered. The first step, however, towards the discovery of cinchonina and quinia appears to have been taken by the late Dr. Duncan of Edinburgh. He believed the precipitate afforded by the infusion of cinchonina with that of galls, to be a peculiar vegetable principle, and accordingly denominated it *cinchonine*. Dr. Gomez, a Portuguese physician, convinced that the active principle of bark resided in this cinchonine, but in an impure state, instituted experiments upon some pale bark, which resulted in the separation of a white crystalline substance, considered by him to be the pure *cinchonine* of Dr. Duncan. It was obtained by the action of potassa upon an aqueous infusion of the alcoholic extract of the bark, and was undoubtedly the principle now universally known by the name of *cinchonine* or *cinchonina*. But Dr. Gomez was ignorant of its precise nature, considering it to be analogous to resin. M. Laubert afterwards obtained the same principle by a different process, and described it under the name of *white matter* or *pure white resin*. To Pelletier and Caventou was reserved the honour of crowning all these experiments, and applying the results which they obtained to important practical purposes. They demonstrated the alkaline character of the principle discovered by Gomez and Laubert, and gave it definitively the name of *cinchonine*. They discovered in the yellow or Calisaya bark another alkaline

principle which they denominated *quinine*. Both these bases they proved to exist naturally in the barks, combined with the *kinic acid* in the state of *kinate of cinchonine* and of *quinine*. It has moreover been established by their labours, that the febrifuge property of bark depends upon the presence of these two principles. It was in the year 1820 that these chemists announced their discovery. Dr. Duncan's suggestion was made so early as 1803. Among English and American chemists, the names of these alkaline bodies have been changed to *cinchonia* and *quinia*, for the sake of uniformity of nomenclature; and by these names we shall always call them.*

It has before been stated, on more than one occasion, that the three official varieties of bark are distinguished by peculiarities of composition. We give the result of the analysis of each variety as obtained by Pelletier and Caventou. (*Journ. de Pharm.* vii. 70. 89. 92.)

Pale bark of Loxa contains, 1. a fatty matter, discovered by Laubert; 2. a red colouring matter, very slightly soluble, identical with the cinchonic red of Reuss; 3. a yellow colouring matter, observed by Laubert, soluble in water and alcohol, and capable of being precipitated by the subacetate of lead; 4. tannin; 5. gum; 6. starch; 7. lignin; 8. kinate of lime; 9. *kinate of cinchonia*, with a very minute proportion of *kinate of quinia*.

Yellow Calisaya bark contains the fatty matter, the cinchonic red, the yellow colouring matter, tannin, starch, lignin, kinate of lime, and *acidulous kinate of quinia*, with a comparatively small proportion of *kinate of cinchonia*.†

Red bark contains the fatty matter, a large quantity of the cinchonic red, the yellow colouring matter, tannin, starch, lignin, kinate of lime, and a large proportion both of *acidulous kinate of quinia*, and of *acidulous kinate of cinchonia*.

Carthagena bark contains the same ingredients with the red bark, but in different proportions. It has less of the alkaline matter, which it also yields with much greater difficulty to water, in consequence of the abundance of insoluble cinchonic red which it contains, and which either involves the salts of quinia and cinchonia so as to prevent the full contact of water, or retains these alkalies in a species of combination. (*Journ. de Pharm.* vii. 105.)

By the experiments of Henry Jun. and Plisson, it may be considered as established, that the alkalies of the different varieties of bark are combined at the same time with kinic acid, and with one or more of the colouring

* In a previous note it has been stated that Pelletier and Coriol had discovered an alkali called *aricina* in the Arica or Cusco bark. It was obtained by the same process as that employed in the extraction of quinia from yellow bark. It is white, crystallizable, and distinguishable from cinchonia, which it in many respects resembles, by exhibiting a green colour under the action of nitric acid, and by the property possessed by its sulphate, of forming a tremulous jelly when a saturated boiling solution of the salt is allowed to cool. Aricina, in the present state of our knowledge respecting it, is of no practical importance.

† Winkler is said to have discovered in Calisaya bark a peculiar bitter principle, which he found also in greater proportion in the *new bark* (*kina nova*), and for which he proposes the name of *kinovic bitter*. It is insoluble in water, soluble in alcohol and ether, without alkaline or acid properties, and without nitrogen in its composition. Winkler obtained it from the *new bark* by treating this in fine powder with ether, evaporating the ether, treating the residue with alcohol, then decolorizing the solution by means of animal charcoal, and precipitating the bitter principle by ammonia. It exists in the *new bark* along with a peculiar acid discovered by Pelletier and Caventou, and denominated by them *kinovic acid*. This acid is somewhat analogous to the stearic, being white, shining, light, slightly soluble in water, and readily soluble in alcohol and ether.

matters, which, in relation to these substances, appear to act the part of acids. This idea was originally suggested by Robiquet. (*Journ. de Pharm.* xii. 282. 369.) It is stated that the compounds of quinia and cinchonia with the cinchonic red are scarcely soluble in water, while the kinates of these bases are very soluble. (*Ibid.* xvii. 201.)

From the statements above made, it appears that the three officinal varieties of bark differ little except in the proportion of their constituents. All contain both quinia and cinchonia; the yellow bark abounding in the first, the pale in the second, and the red in both. Gum is the only constituent found in one and not in the others. It is an ingredient in the pale bark, but is wanting in the red and yellow.

The odour of bark appears to depend on a *volatile oil* which Fabroni and Trommsdorff obtained by distillation with water. The oil floated on the surface of the water, was of a thick consistence, and had a bitterish acrid taste, with the odour of bark.

The *fatty matter*, which was first obtained pure by M. Laubert, is of a greenish colour as obtained from the pale bark, orange-yellow from the yellow. It is insoluble in water, soluble in boiling alcohol, which deposits a part of it on cooling, very soluble in sulphuric ether even cold, and capable of forming soaps with the alkalies. The colour is probably owing to extraneous matter connected with it.

The *cinchonic red* of Reuss, the *insoluble red colouring matter* of Pelletier and Caventou, is reddish-brown, insipid, inodorous, largely soluble in alcohol, especially when hot, and almost insoluble in ether or water, though the latter dissolves a little at the boiling temperature. The acids promote its solubility in water. It precipitates tartar emetic, but not gelatin; but, if treated with a cold solution of potassa or soda, or by ammonia, lime, or baryta with heat, and precipitated by an acid from the solution thus formed, it acquires the property of forming an insoluble compound with gelatin, and seems to be converted into a species of tannin. It is precipitated by subacetate of lead. It is most abundant in the red bark, and least so in the pale. Berzelius supposes it to consist of tannin and apothème, and to be formed from tannin by the action of the air.

The *yellow colouring matter* has little taste, is soluble in water, alcohol, and ether, precipitates neither gelatin nor tartar emetic, and is itself precipitated by subacetate of lead.

The *tannic acid*, *tannin*, or *soluble red colouring matter* of Pelletier and Caventou, has been considered as possessing all the properties which characterize the proximate vegetable principles associated together under this name. It has a brownish-red colour and austere taste, is soluble in water and alcohol, combines with metallic oxides, and produces precipitates with the salts of iron, which vary in colour according to the variety of bark; being deep green with the pale bark, blackish-brown with the yellow, and reddish-brown with the red. It also forms white precipitates with tartar-emetic and gelatin, and readily combines with atmospheric oxygen, becoming insoluble. It must, however, differ materially from the tannin or tannic acid of galls, which could not exist in aqueous solutions containing cinchonia without forming an insoluble compound with that base.

But the most interesting and important constituents of Peruvian bark are the cinchonia and quinia, and the acid with which they are combined. In relation to these, therefore, we shall be more minute in our details.

Cinchonia when pure is a white crystalline substance, soluble in two thousand five hundred parts of boiling water, almost insoluble in cold water,

very soluble in boiling alcohol, which deposits a portion in the crystalline state upon cooling, and slightly soluble in ether and the fixed and volatile oils. Its bitter taste, at first not very obvious in consequence of its difficult solubility, is developed after a short time by the solution of a minute portion in the saliva. Its alcoholic, ethereal, and oleaginous solutions are very bitter. By heat it is at the same time melted and decomposed. Its alkaline character is very decided, as it neutralizes the strongest acids, forming with them saline compounds. Of the salts of cinchonia, the sulphate, nitrate, muriate, phosphate, and acetate are soluble in water. The neutral tartrate, oxalate, and gallate are insoluble in cold water, but may be dissolved in hot water, in alcohol, or in an excess of acid. Several processes have been employed for the preparation of cinchonia. One of the simplest is the following. Powdered pale bark is submitted to the action of sulphuric or muriatic acid very much diluted, and the solution thus obtained is precipitated by an excess of lime. The precipitate is collected on a filter, washed with water, and treated with boiling alcohol. The alcoholic solution is filtered while hot, and deposits the cinchonia when it cools. A further quantity is obtained by evaporation. If not perfectly white, it may be freed from colour by first converting it into a sulphate with dilute sulphuric acid, then treating the solution with animal charcoal, filtering, precipitating by an alkali, and redissolving by alcohol in the manner already mentioned. It may also be obtained from the mother waters of sulphate of quinia, by diluting them with water, precipitating with ammonia, collecting the precipitate on a filter, washing and drying it, and then dissolving it in boiling alcohol, which deposits the cinchonia in a crystalline form upon cooling. It may be still further purified by a second solution and crystallization. Cinchonia consists of 20 equivalents of carbon, 12 of hydrogen, 1 of oxygen, and 1 of nitrogen ($C_{20}H_{12}ON$); and its combining number may be stated at 156.55, hydrogen being considered as unity. Exposed to the air, it does not suffer decomposition, but very slowly absorbs carbonic acid, and acquires the property of effervescing slightly with acids. It may be distinguished, when dissolved in the saline state in water, from any other vegetable alkali, by a reddish somewhat orange colour, produced by the addition first of liquid chlorine and then of ammonia to the solution. (*Journ. de Pharm.* xxii. 135.)

Sulphate of cinchonia, or more strictly *disulphate of cinchonia*, the only salt of this base which has been employed to any extent in a separate state, may be prepared by heating cinchonia with a little water, adding dilute sulphuric acid gradually till the alkali is dissolved, then boiling with animal charcoal previously washed with muriatic acid, filtering the solution while hot, and setting it aside to crystallize. By alternate evaporation and crystallization, the whole of the sulphate may be obtained from the solution. It is a white, very bitter salt, crystallizing in flexible, somewhat shining, four-sided, flattened prisms, terminated by an inclined face, and generally collected in fasciculi. It is soluble in fifty-four parts of water at common temperatures, and in a smaller quantity of boiling water. Chemists at present generally consider it as a *disulphate*. By the addition of the necessary quantity of acid, it passes into the neutral sulphate, which is soluble in less than half its weight of water at 58° . It consists, according to Pelletier and Caventou, of 100 parts of cinchonia, and 13.021 of sulphuric acid. (*Journ. de Pharm.* vii. 57.)

Quinia (QUINA, *Lond.*) is whitish, and as usually prepared is rather flocculent in its appearance, not crystalline like cinchonia. It may, however, be crystallized, by cautious management, from its alcoholic solution,

in pearly silky needles. (*Journ. de Pharm.* xi. 249.) It is fusible without chemical change, at about 300° F., and becomes brittle on cooling. It is more bitter than cinchonia, is almost insoluble in water, but is very soluble in alcohol, and soluble also in ether, and in the fixed and volatile oils. Its alcoholic solution is intensely bitter. It unites with the acids to form salts, which crystallize with facility. The gallate, tartrate, and oxalate are said to be insoluble, or nearly so, in cold water, but are dissolved by an excess of acid. It is unalterable in the air, not even absorbing carbonic acid. Its salts may be distinguished from those of the other vegetable alkalies by the beautiful emerald green colour which results when their solution is treated first with solution of chlorine and then with ammonia, and which changes to a white or violet upon saturation with a dilute acid. (*Journ. de Pharm.* xxii. 135.) Quinia consists of 20 equivalents of carbon, 12 of hydrogen, 2 of oxygen, and 1 of nitrogen ($C_{20}H_{12}O_2N$); and its combining number is 164.55. This number, however, is founded on the opinion, that of the two salts which quinia forms with sulphuric acid, the one originally considered neutral, and denominated simply sulphate of quinia is in fact basic, consisting of two equivalents of the base, and one of the acid, while the other, at first supposed to be a supersalt, is strictly neutral, consisting of one equivalent of each of its ingredients. The same remark is applicable to the combining number of cinchonia. In both cases, were the original opinion of the composition of the sulphates to be admitted, the real combining numbers of the two alkalies would be double those already stated. Quinia is obtained by treating its sulphate with the solution of an alkali, collecting the precipitate which forms, washing it till the water comes away tasteless, then drying it, dissolving it in alcohol, and slowly evaporating the solution.

The only important artificial salt of quinia is the sulphate, the process for procuring which, as well as its properties, will be hereafter described. (See *Quiniæ Sulphas*, among the Preparations.) The *muriate*, *phosphate*, *acetate*, *citrate*, *ferrocyanate*, and *tannate* have also been employed and recommended, but none of them has yet gained a reputation which entitles it to rank among standard remedies. The first four may be prepared by saturating a solution of the acids respectively with quinia, and evaporating the solutions. The *ferrocyanate* is made by boiling together two parts of sulphate of quinia and three of ferrocyanuret of potassium in a very small quantity of water, pouring off the liquors from a greenish-yellow substance of an oily consistence which is precipitated, washing the latter with distilled water, then dissolving it in strong alcohol at 100° F., filtering immediately, and afterwards evaporating the solution. (See *Am. Journ. of Pharm.* xii. 351.) The *tannate* may be prepared by precipitating the infusion of bark, or solution of sulphate of quinia, by the infusion of galls or solution of tannic acid, and then washing and drying the precipitate. Either of these salts may be given in the same dose as the sulphate.

Kinic Acid, (called also *Cinchonic*, or *Quinic Acid*), and the *Kinates* of *Cinchonia* and *Quinia*. It may be desirable to procure the alkaline principles in that state of saline combination in which they exist in the bark, as it is possible that they may exert an influence over the system in this state, somewhat different from that produced by their combinations with the sulphuric or other mineral acid. As it is impossible to procure the kinates immediately from the bark in a pure state, it becomes necessary first to obtain the kinic acid separately, which may thus become of some practical importance. We shall, therefore, briefly describe the mode of procuring it, and its characteristic properties. By evaporating the infusion of bark to a solid consistence, and treating the extract thus obtained with alcohol, we have in the

residue a viscid matter consisting chiefly of mucilage and kinate of lime.* If an aqueous solution of this substance be formed, and allowed to evaporate at a gentle heat, crystals of the kinate are deposited, which may be purified by a second crystallization. The salt thus obtained, being dissolved in water, is decomposed by means of oxalic acid, which precipitates the lime and leaves the *kinic acid* in solution. This may be procured in the crystalline state by spontaneous evaporation, though as usually prepared it is in the form of a thick syrupy liquid. The crystals are transparent and colourless, sour to the taste, and readily soluble in alcohol and water. The kinates of cinchonia and quinia may be obtained either by a direct combination of their constituents, or by the mutual decomposition of the sulphates of those alkalies and the kinate of lime. 'The *kinate of cinchonia* has a bitter and astringent taste, is very soluble in water, is soluble also in alcohol, and is crystallized with difficulty. 'The *kinate of quinia* is also very soluble in water, but less so in rectified alcohol. Its taste is very bitter, resembling exactly that of yellow bark. It crystallizes in crusts of a mammillated form, and opaque or semitransparent. 'The salt is with difficulty obtained free from colour, and only by employing the ingredients in a state of extreme purity. (*Ann. de Chim. et de Phys. Juillet, 1829.*)

Of the relations of bark with the several solvents employed in pharmacy we shall speak hereafter, under the heads of its infusion, decoction, and tincture; where we shall also have an opportunity of mentioning some of the more prominent substances which afford precipitates with its liquid preparations. It is sufficient at present to state, that all the substances which precipitate the infusion of bark do not by any means necessarily affect its virtues; as it contains several inert ingredients which form insoluble compounds with bodies which do not disturb its active principles. As tannic acid forms with quinia and cinchonia a compound insoluble in water, it is desirable that substances containing this acid, in a free state, should not be prescribed in connexion with the infusion or decoction of bark; for, though it is not improbable that this insoluble tannate might be found efficacious if administered, yet being precipitated from the liquid, it would be apt to be thrown away as dregs, or at any rate would communicate, if agitated, an unpleasant turbidness.

It is evident from what has been said, that an infusion of bark, on account of the tannin-like principle which it contains, may precipitate gelatin, tartar emetic, and the salts of iron, without having a particle of cinchonia or quinia in its composition; and that consequently any inference as to its value drawn from this chemical property, would be altogether fallacious: but, as the active principles are thrown down by the tannic acid of galls, no bark can be considered good which does not afford a precipitate with the infusion of this substance.

It is impossible to determine, with accuracy, the relative proportion of the active ingredients in the different varieties of cinchona; as the quantity is by no means uniform in different specimens of the same variety. Pelletier and Caventou state, in their first Memoir, that they had been able to obtain only 2 parts of cinchonia from 1000 of pale bark; while from an equal quantity of the yellow they had succeeded in extracting 9 parts of quinia, and from the red, 8 parts of cinchonia and 17 parts of quinia. (*Journ. de Pharm. vii. 92.*) But either they employed inferior specimens of the first two varieties, or did not completely exhaust those upon which they experimented. According to a statement subsequently made by them to the French Institute,

* The kinate of lime is soluble in water, but not in alcohol.

they obtained from the best Calisaya bark 2·9 per cent. of sulphate of quinia, from inferior kinds 1·5 per cent.; and the average result was 2·33 per cent. (*North. Am. Med. and Surg. Journ.* v. 475.) Accounts generally agree in giving less alkaline matter to the pale barks than to the yellow, and more to the red than to either. Mr. Viltmann of Osnabruck obtained from the Huauuco bark 3·5 per cent. of cinchonina, from the Calisaya or royal yellow, 5 per cent. of quinia, from the red, 6 per cent. of quinia and cinchonina, and from the Carthagena, 3·3 per cent. of alkaline matter. (*Journ. de Chim. Medicale*, Nov. 1830.) We cannot, however, avoid suspecting some inaccuracy in the steps by which he obtained results so far exceeding those of the experienced French chemists before quoted.

The following mode of estimating the value of bark by the quantity of alkaline matter it contains, we copy from a communication of M. Tilloy of Dijon, published in the 13th vol. of the *Journ. de Pharmacie*, p. 330. "Take an ounce of the bark coarsely powdered, introduce it into about 12 ounces of alcohol of 30° B. (sp. gr. 0·8748), expose the mixture for half an hour to a temperature of from 105° to 120° F., draw off the alcohol, add a fresh portion, and act as before; unite the liquors, and throw into them a sufficient quantity of acetate or subacetate of lead to precipitate the colouring matter and kinic acid, then allow the insoluble matter to subside, and filter. Add to the filtered liquor a few drops of sulphuric acid to separate the excess of acetate of lead, filter, and distil off the alcohol. There remains an acetate or sulphate of quinia, according to the quantity of sulphuric acid employed, together with a fatty matter which will adhere to the vessel. Decant the liquor, and add ammonia, which will instantaneously precipitate the quinia. Too much ammonia will retain it in solution, but in this case a few drops of sulphuric acid will cause it to precipitate. The quinia washed with warm water, and then treated with sulphuric acid, water, and a little animal charcoal, yields very white sulphate of quinia. I have thus obtained in six hours nine grains of the sulphate from an ounce of bark [576 grains French], which is a large proportion when allowances are made for the loss during the process." The Edinburgh Pharmacopœia gives the following mode of testing the value of yellow bark. "A filtered decoction of 100 grains in two fluidounces of distilled water gives, with a fluidounce of concentrated solution of carbonate of soda, a precipitate, which, when heated in the fluid, becomes a fused mass, weighing when cold two grains or more, and easily soluble in solution of oxalic acid."

Medical Properties and Uses.

This valuable remedy was unknown to the civilized world till about the middle of the seventeenth century; though the natives of Peru are generally supposed to have been long previously acquainted with its febrifuge powers. Humboldt, however, is of a different opinion. In his Memoir on the Cinchona forests, he states that it is entirely unknown as a remedy to the Indians inhabiting the country where it grows; and as these people adhere with pertinacity to the practices of their ancestors, he concludes that it never was employed by them. They have generally the most violent prejudices against it, considering it absolutely poisonous; and in the treatment of fever prefer the milder indigenous remedies. Humboldt is disposed to ascribe the discovery of the febrifuge powers of the bark to the Jesuits, who were sent to Peru as missionaries, and among whom were many familiar with the medical knowledge of the day. As bitters had been chiefly relied on in the treatment of intermittent fevers, and as bitterness was observed to be a pre-

dominant property in the bark of certain trees which were felled in clearing the forests, the missionaries were naturally led to give it a trial in the same complaint. They accordingly administered an infusion of the bark in the tertian ague, then a prevalent disorder in Peru, and soon ascertained its extraordinary powers. A tradition to this effect is said by Humboldt to be current at Loxa. Ruiz and Pavon, however, are among the writers who ascribe the discovery to the Indians. The Countess of Chinchon, wife of the Viceroy of Peru, having in her own person experienced the beneficial effects of the bark, is said, on her return to Spain in the year 1640, to have first introduced the remedy into Europe. Hence the name of *pulvis Commitissæ*, by which it was first known. After its introduction, it was distributed and sold by the Jesuits, who are said to have obtained for it the enormous sum of its weight in silver. From this circumstance it was called *Jesuits' powder*, a title which it long retained. It had acquired some reputation in England so early as the year 1658, but from its extravagant price, and from the prejudice excited against it, was at first little used. At this early period, however, its origin and nature do not seem to have been generally known; for we are told that Sir John Talbot, an Englishman, having employed it with great success in France, in the treatment of intermittents, under the name of the English powder, at length, in the year 1679, sold the secret of its origin and preparation to Louis XIV., by whom it was divulged.

When taken into the stomach, bark usually excites in a short time a sense of warmth in the epigastrium, which often diffuses itself over the abdomen and even the breast, and is sometimes attended with considerable gastric and intestinal irritation. Nausea and even vomiting are sometimes produced, especially if the stomach was previously in an inflamed or irritated state. Purging, moreover, is not an unfrequent attendant upon its action. After some time has elapsed, the circulation often experiences its influence, as exhibited in the somewhat increased frequency of pulse; and if the dose be repeated, the whole system becomes more or less affected, and all the functions undergo a moderate degree of excitement. Its action upon the nervous system is often evinced by a sense of tension or fulness or slight pain in the head, singing in the ears, and partial deafness, which are always experienced by some individuals when brought completely under its influence. The effects above mentioned entitle bark to a place among the tonics, and it is usually ranked at the very head of this class of medicines. But besides the mere excitation of the ordinary functions of health, it produces other effects upon the system, which must be considered peculiar, and wholly independent of its mere tonic operation. The power by which, when administered in the intervals between the paroxysms of intermittent disorders, it breaks the chain of morbid association, and interrupts the progress of the disease, is something more than what is usually understood by the tonic property; for no other substance belonging to the class, however powerful or permanent may be the excitement which it produces, exercises a control over intermittents at all comparable to that of the medicine under consideration. As in these complaints it is probable that, in the intervals, a train of morbid actions is going on out of our sight, within the recesses of the nervous system; so it is also probable, that bark produces in the same system an action equally mysterious, which supersedes that of the malady, and thus accomplishes the restoration of the patient. From the possession both of the tonic, and of the *anti-intermittent* property, if we may be allowed so to designate it, bark is capable of being usefully applied in the treatment of a great number of diseases.

It may usually be employed with benefit in all morbid conditions of the

system, whatever may be the peculiar modifications, in which a permanent corroborant effect is desirable, provided the stomach be in a proper state for its reception. In low or typhoid forms of disease, in which either no inflammation exists, or that which does exist has been moderated by proper measures, or has passed into the suppurative or the gangrenous stage, this remedy is often of the greatest advantage in supporting the system till the morbid action ceases. Hence its use in the latter stages of typhus gravior; in malignant scarlatina, measles, and small pox; in carbuncle, and gangrenous erysipelas; and in all cases in which the system is exhausted under large purulent discharges, and the tendency of the affection is towards recovery. As a tonic, bark is also advantageously employed in chronic diseases connected with debility; as, for example, in scrofula, dropsy, passive hemorrhages, certain forms of dyspepsia, obstinate cutaneous affections, amenorrhœa, chorea, hysteria; in fact, whenever a corroborant influence is desired, and no contra-indicating symptoms exist. But in all these cases it greatly behooves the physician to examine well the condition of the system, and before resorting to the tonic, to ascertain the real existence of an enfeebled condition of the functions, and the absence of such local irritations or inflammations, especially of the stomach or bowels, as would be likely to be aggravated by its use. In doubtful cases, we have been in the habit of considering the occurrence of profuse sweating during sleep as affording an indication for its use, and, under these circumstances, have prescribed it very advantageously, in the form of sulphate of quinia, in acute rheumatism, and the advanced stages of protracted fevers.

But it is in the cure of intermittent diseases that bark displays its most extraordinary powers. It was originally introduced into notice as a remedy in fever and ague, and the reputation which it acquired at an early period it has ever since retained. Very few cases of this disease will be found to resist the judicious use of bark, or some one of its preparations. This is not the place to speak of the precise circumstances under which it is best administered. It will be sufficient to say, that physicians generally concur in recommending its early employment, in divided doses, to the extent of one or two ounces, during the intermission, and the repetition of this plan till the disease is subdued, or the remedy is found insufficient for its cure. Other intermittent diseases have been found to yield with almost equal certainty to the remedy, particularly those of a neuralgic character. Hemicrania and violent pains in the eye, face, and other parts of the body, occurring periodically, are often almost immediately relieved by the use of bark. Some cases of epilepsy, in which the convulsions recurred at regular intervals, have also been cured by it; and even the hectic intermittent is frequently arrested, though, as the cause still generally continues to operate, the relief is too often only temporary. Diarrhœa and dysentery sometimes put on the intermittent form, especially in miasmatic districts; and under these circumstances may often be cured by bark. Nor is it necessary, that, in the various diseases which have been mentioned, the intermission should always be complete, in order to justify a resort to the remedy. Remittent fevers, in which the remission is very decided, not unfrequently yield to the use of bark, if preceded by proper depleting measures. But, as a general rule, the less of the diseased action there is in the interval, the better is the chance of success; and if it exceed a certain point, the bark has usually been found to aggravate instead of relieving the complaint.

Some observations are requisite as to the choice of the barks, and the forms of administration. In the treatment of intermittents, either the red or the yellow bark is decidedly preferable to the pale, and of the first two, the

red is usually considered the most powerful. With regard to the red, experience had pronounced in its favour long before analysis had proved its superiority. It not only contains more of the active principles of the bark than the other varieties, but has also the advantage of uniting them both in nearly equal proportion. The pale bark may possibly, in its finest forms, be superior for the purposes of a general tonic; as it is less liable to offend the stomach, and perhaps to irritate the bowels.

Where the object is to obtain the full influence of bark, it is most effectually administered in substance. We can by no means be absolutely certain that quinia and cinchonia are its only active ingredients; and even supposing them to be so, we are equally uncertain whether they may not be somewhat modified in their properties, even by the therapeutically inert principles with which they are associated. In fact, bark in substance has been repeatedly known to cure intermittents when the sulphate of quinia has failed. It is best administered diffused in water or some aromatic infusion. Experience has proved that its efficacy in the cure of intermittents is often greatly promoted by admixture with other substances. A mixture of powdered bark, Virginia snakeroot, and carbonate of soda, was at one time highly esteemed in this city; and another, consisting of bark, confection of opium, lemon-juice, and port wine, has, in our own experience, and that of some of our friends, proved highly efficacious in some obstinate cases of fever and ague.*

But notwithstanding the superior efficacy of the bark in substance, it is in the great majority of instances sufficient to resort to some one of its preparations; and in many cases we are compelled to this resort by the inability of the stomach to support the powder, or the unwillingness of the patient to encounter its disagreeable taste. The best substitute, in cases of intermittent disease, is decidedly the sulphate of quinia, or sulphate of cinchonia, the former of which is used almost to the exclusion of the latter, though not perhaps upon sufficient grounds. The advantage of these preparations is their great facility of administration, and the possibility, by their employment, of introducing a large quantity of the active matter, with less risk of offending the stomach. The sulphate of quinia is now almost universally employed in the treatment of intermittents, and bark resorted to only after this has failed. (See *Quiniæ Sulphas*.)

Though quinia possesses the anti-intermittent power of bark, it is by no means satisfactorily ascertained that it is capable of exerting all the peculiar influence of that medicine as a tonic; but as bark in powder can seldom be supported by a delicate stomach, for a sufficient period to insure the necessary influence of the medicine in chronic disease, it is customary to resort, in this case, to some one of its preparations in which the quinia is extracted in connection with the other principles; as the infusion, decoction, tincture, and extract. Each of these will be particularly treated of among the preparations. It is here only necessary to say, that their use is mostly confined to chronic cases; or to those of a malignant character, as typhus gravior, &c., in which the whole virtues of bark are desired, but the stomach is unable to bear the powder. Should bark or its preparations produce purging, as they occasionally do, they should be combined with a small proportion of laudanum.

* The following are the formulæ for these mixtures. 1. *R Cinchon. pulv. ʒss; Serpentariæ pulv. ʒj; Sodæ Carbonat. ʒss; Misce et in pulveres quatuor divide, una tertia vel quarta quæque horâ sumenda.* 2. *R Cinchon. Rub. pulv. ʒss; Confect. Opii ʒj; Suc. Limon. recentis fʒij; Vin. Oporto fʒiv; Misce. Tertia pars, tertiâ quæque horâ sumenda.*

It is sometimes desirable to introduce bark into the system by other surfaces than that of the stomach; and it has been found to exercise its peculiar influence to whatever part it has been applied. Injected into the rectum, in connexion with opium to prevent purging, it has been employed successfully in the cure of intermittents; and the use of bark jackets, made by quilting the powder between two pieces of flannel or muslin, and worn next the skin, and of bark baths made by infusing the medicine in water, has proved serviceable in cases of children. But the best preparation of bark for external application is decidedly sulphate of quinia, which, sprinkled upon a blistered surface denuded of the cuticle, is speedily absorbed, and produces on the system effects not less decided than those which result from its internal administration.

The medium dose of bark, as administered in intermittents, is a drachm, to be repeated more or less frequently according to circumstances. When given as a tonic in chronic complaints, the dose is usually smaller; from ten to thirty grains being sufficient to commence with.

CASSIA.—Cassia lignea; Casse, *Fr.*; Cassienzimmit, *Germ.*; Cannellina, *Ital.*; Casia, *Span.*

The *U. S. Pharmacopœia* embraces, under the title of cinnamon, not only the bark of that name obtained from the island of Ceylon, but also the commercial cassia, which is imported from China; and as the two products, though very different in price, and somewhat in flavour, possess identical medical properties, and are used for the same purposes, there seems to be no necessity for giving them distinct officinal designations. Indeed, the barks of all the species of the genus *Cinnamomum*, possessing analogous properties, are as much entitled to the common name of cinnamon, as those of the *Cinchona*s have to the name of cinchona, and the juice of different species of *Aloe*, to that of aloes. Varieties may be sufficiently distinguished by an appropriate epithet. Both *cinnamomum* and *cassia* were terms employed by the ancients, but whether exactly as now understood, it is impossible to determine. The term *cassia* or *cassia lignea* has been generally used in modern times to designate the coarser barks analogous to cinnamon. It was probably first applied to the barks from Malabar, and afterwards extended to those of China and other parts of Eastern Asia. It has been customary to ascribe *cassia lignea* to the *Laurus Cassia* of Linnæus; but

the specific character given by that botanist was so indefinite, and based on such imperfect information, that the species has been almost unanimously abandoned by recent botanists. The fact appears to be, that the barks sold as cinnamon and cassia in different parts of the world are derived from various species of *Cinnamomum*. Dr. Wight, who was commissioned by the British Indian Government to inquire into the botanical source of "the common cassia bark of the markets of the world," expresses his belief that the list of plants yielding this product extends to nearly every species of the genus, including not less than six plants on the Malabar coast and in Ceylon, and nearly twice as many more in the Eastern part of Asia, and the islands of the Eastern Archipelago. (*Madras Journ. of Literat. and Sci.*, 1839, No. 22.) We shall describe only the two species recognised by the U. S. Pharmacopœia.

CINNAMOMUM. *Sex. Syst.* Enneandria Monogynia.—*Nat. Ord.* Lauracæ.

Gen. Ch. Flowers hermaphrodite or polygamous, panicle or fascicled, naked. *Calyx* six-cleft, with the limb deciduous. *Fertile stamens* nine, in three rows; the inner three with two sessile glands at the base; *anthers* four-celled, the three inner turned outwards. Three capitate *abortive stamens* next the centre. *Fruit* seated in a cup-like calyx. *Leaves* ribbed. *Leaf buds* not scaly. (*Lindley.*)

1. *Cinnamomum Zeylanicum*. Nees, *Laurineæ*, 52; *Lindley, Med. Flor.* 329; Hayne, *Darstel. und Beschreib. &c.* xii. 263.—*Laurus Cinnamomum*. Linn. This is a tree about twenty or thirty feet high, with a trunk from twelve to eighteen inches in diameter, and covered with a thick, scabrous bark. The branches are numerous, strong, horizontal and declining; and the young shoots are beautifully speckled with dark green and light orange colours. The leaves are opposite for the most part, coriaceous, entire, ovate, or ovate-oblong, obtusely pointed, and three-nerved, with the lateral nerves vanishing as they approach the point. There are also two less obvious nerves, one on each side, arising from the base, proceeding towards the border of the leaf, and then quickly vanishing. The footstalks are short and slightly channeled, and together with the extreme twigs are smooth and without the least appearance of down. In one variety, the leaves are very broad, and somewhat cordate. When mature they are of a shining green upon their upper surface, and lighter-coloured beneath. The flowers are small, white, and arranged in axillary and terminal panicles. The fruit is an oval berry, which adheres like the acorn to the receptacle, is larger than the black currant, and when ripe has a bluish-brown surface diversified with numerous white spots.

The tree emits no smell perceptible at any distance. The bark of the root has the odour of cinnamon with the pungency of camphor, and yields this principle upon distillation. The leaves have a spicy odour when rubbed, and a hot taste.* The petiole has the flavour of cinnamon. It is a singular fact, that the odour of the flowers is to people in general disagreeable, being compared by some to the scent exhaled from newly sawn bones. The fruit when opened has a terebinthinate odour, and a taste in some degree like that of Juniper berries. It is the prepared bark that constitutes the spice so well known and so highly valued under the name of cinnamon.

This species of *Cinnamomum* is a native of Ceylon, where it has long been cultivated for the sake of its bark. It is said also to be a native of the Malabar coast, and has at various periods been introduced into Java, the

* Dr. Ruschenberger states that the leaves have a strong odour of cloves when broken and rubbed, and a "clove" oil is obtained from them by distillation, which yields considerable profit. (*Voyage round the World*, p. 207.)

Isle of France, Bourbon, the Cape de Verds, Brazil, Cayenne, several of the West India Islands, and Egypt; and in some of these places is at this time highly productive. This is particularly the case in Cayenne, where the plant was flourishing so early as the year 1755. It is exceedingly influenced, as regards the aromatic character of its bark, by the circumstances of soil, climate, and mode of culture. Thus we are told by Marshall that in Ceylon, beyond the limits of Negombo and Matura, in the western and southern aspect of the island, the bark is never of good quality, being greatly deficient in the spicy, aromatic flavour of the cinnamon; and that even within these limits it is of unequal value from the various influence of exposure, soil, shade, and other circumstances.

2. *C. aromaticum*. Nees, *Laurineæ*, 52; Lindley, *Flor. Med.* 330.—*C. Cassia*. Blume; Ed. Ph.; Hayne, *Darstel. und Beschreib. &c.* xii. 23.—*Laurus Cassia*. Aiton, *Hort. Kew.* ii. 427.—Not *Laurus Cassia* of Linn. This is a tree of about the same magnitude as the former species, and like it has nearly opposite, shortly petiolate, coriaceous, entire leaves, of a shining green upon the upper surface, lighter coloured beneath, and furnished with three nerves, of which the two lateral vanish towards the point. The leaves, however, differ in being oblong-lanceolate and pointed, and in exhibiting, under the microscope, a very fine down upon the under surface. The foot-stalks and extreme twigs are also downy. The flowers are in narrow, silky panicles. The plant grows in China, Sumatra, and probably in other parts of Eastern Asia, and is said to be cultivated in Java. It is believed to be the species which furnishes, wholly or in part, the Chinese cinnamon or cassia brought from Canton, and is supposed also to be the source of the *cassia buds* of commerce.

Besides the two species above described, others have been thought to contribute to the cinnamon and cassia found in commerce. The opinion of Dr. Wight has been already stated. The *C. Loureirii* of Nees, growing in the mountains of Cochin-china towards Laos, and in Japan, affords, according to Loureiro, a cinnamon, of which the finest kind is superior to that of Ceylon. The *C. nitidum*, growing in Ceylon, Java, and upon the continent of India, is said to have been the chief source of the drug, known formerly by the name of *Folia Malabathri*, and consisting of the leaves of different species of *Cinnamomum* mixed together. The leaves of the *C. Tamala* of Hindostan have been sold under the same name. The *C. Culilawan* of the Moluccas yields the aromatic bark called Culilawan, noticed in the *Appendix*; and similar barks are obtained from another species of the same region, denominated *C. rubrum*, and from the *C. Sintoc* of Java.

Culture, Collection, Commerce, &c. Our remarks under this head will first be directed to the cinnamon of Ceylon, in relation to which we have more precise information than concerning the aromatic obtained from other sources. The bark was originally collected exclusively from the tree in a wild state; but under the government of the Dutch the practice of cultivating it was introduced, and it has been continued since the British have come into possession of the island. The principal cinnamon gardens are in the vicinity of Columbo. The seeds are planted in a prepared soil at certain distances, and as four or five are placed in a spot, the plants usually grow in clusters like the hazel bush. In favourable situations they attain the height of five or six feet in six or seven years, and a healthy bush will then afford two or three shoots fit for peeling; and every second year afterwards will afford from four to seven shoots in a good soil. The cinnamon harvest commences in May and continues till late in October. The first object is to select shoots proper for decortication, and those are seldom cut which are

less than half an inch, or more than two or three inches in diameter. The bark is divided by longitudinal incisions, of which two are made opposite to each other in the smaller shoots, several in the larger, and is then removed in strips by means of a suitable instrument. The pieces are next collected in bundles, and allowed to remain in this state for a short time, so as to undergo a degree of fermentation which facilitates the separation of the cuticle. The epidermis and the green matter beneath it are removed by placing the strip of bark upon a convex piece of wood, and scraping its external surface with a curved knife. The bark now dries and contracts, assuming the appearance of a quill. The peeler introduces the smaller tubes into the larger, thus forming a congeries of quills into a cylindrical pipe which is about forty inches long. When sufficiently dry, these cylinders are collected into bundles weighing about thirty pounds, and bound together by pieces of split bamboo. The commerce in Ceylon cinnamon was formerly monopolized by the East India Company; but the cultivation is now unrestricted, and the bark may be freely exported upon the payment of a duty of three shillings sterling a pound. (*Ruschenberger*.) It is assorted in the island into three qualities, distinguished by the designations of *first*, *second*, and *third*. The inferior kinds, which are of insufficient value to pay the duty, are used for the preparation of oil of cinnamon. Formerly, according to Marshall, they were exported to the continent of India, whence a portion was said to reach Europe under the name of cassia.

Immense quantities of cinnamon are exported from China, the finest of which is little inferior to that of Ceylon, though the mass of it is much coarser. It passes in commerce under the name of *cassia*; and is said by Mr. Reeves to be brought to Canton from the province of Kwangse, where the tree producing it grows very abundantly. (*Trans. Med. Bot. Soc.* 1828, p. 26.) It has already been stated, that this tree is supposed to be the *Cinnamomum aromaticum*; but we have no positive proof of the fact. Travellers inform us that cinnamon is also collected in Cochin-china; but that the best of it is monopolized by the sovereign of the country. It is supposed to be obtained from the *Cinnamomum Loureirii* of Nees, the *Laurus Cinnamomum* of Loureiro. According to Siebold, the bark of the large branches is of inferior quality and is rejected, as it will not bear the expense of carriage; that from the smallest branches resembles the Ceylon cinnamon in thickness, but has a very pungent taste and smell, and is little esteemed; while the intermediate branches yield an excellent bark, about a line in thickness, which is even more highly valued than the cinnamon of Ceylon, and yields on distillation a sweeter and less pungent oil. (*Annal. der Pharm.* xx. 280.) It is highly probable that a portion of the cassia exported from Canton is derived from Cochin-china and the islands of the Indian Archipelago.

Cinnamon of good quality is said to be collected in Java, and considerable quantities of inferior quality have been thrown into commerce, as *cassia lignea*, from the Malabar coast. Manilla and the Isle of France are also mentioned as sources whence this drug is supplied. Little, however, reaches the United States from these places.

Cayenne, and several of the West India Islands, yield to commerce considerable quantities of cinnamon of various qualities. That of Cayenne is of two kinds, one of which closely resembles, though it does not quite equal, the aromatic of Ceylon; the other resembles the Chinese. The former is supposed to be derived from plants propagated from a Ceylonese stock, the latter from those which have sprung from a tree introduced from Sumatra.

By far the greater proportion of cinnamon brought to this country is imported from China. It is entered as *cassia* at the custom house, while the same article brought from other sources is almost uniformly entered as cinnamon. By an examination of the treasury returns from the year 1820 to 1829, we found that the average annual import of this spice was, in round numbers, 652,000 pounds from China, 12,000 pounds from England, 9,000 pounds from the British East Indies, 3,000 pounds from the West Indies, and an insignificant quantity from all other places, with the exception of 12,758 pounds brought in one year from the Philippines. There is no doubt that much of the amount brought from China is exported; but we have not been able to ascertain the proportion.

From what source the ancients derived their cinnamon and cassia cannot now be ascertained with certainty. Neither the plants nor their localities, as described by Dioscorides, Pliny, and Theophrastus, correspond precisely with our present knowledge; but in this respect much allowance must be made for the inaccurate geography of the ancients. It is not improbable that the Arabian or other Eastern navigators, at a very early period, conveyed this spice within the limits of Phœnician and Grecian, and subsequently of Roman commerce.

Properties. *Ceylon cinnamon* is in long cylindrical fasciculi, composed of numerous quills, the larger enclosing the smaller. The finest is of a light brownish-yellow colour, almost as thin as paper, smooth, often somewhat shining, pliable to a considerable extent, with a splintery fracture when broken. It has a pleasant fragrant odour, and a warm, aromatic, pungent, sweetish, slightly astringent, and highly agreeable taste. When distilled it affords but a small quantity of essential oil, which, however, has an exceedingly grateful flavour. It is brought to this country from England; but is very costly, and is not generally kept in the shops. The inferior sorts are browner, thicker, less splintery, and of a less agreeable flavour, and are little if at all superior to the best Chinese. The finer variety of *Cayenne cinnamon* approaches in character to that above described, but is paler and in thicker pieces, being usually collected from older branches. That which is gathered very young, is scarcely distinguishable from the cinnamon of Ceylon. It is not recognised in our markets as a distinct variety.

The *Chinese cinnamon*, called *cassia* in commercial language, is usually in single tubes of various sizes, from an eighth of an inch to half an inch or even an inch in diameter. Sometimes the tubes are double, but very rarely more than double. In some instances the bark is rolled very much upon itself, in others is not even completely quilled, forming segments more or less extensive of a hollow cylinder. It is of a redder or darker colour than the finest Ceylon cinnamon, thicker, rougher, denser, and breaks with a shorter fracture. It has a stronger, more pungent and astringent, but less sweet and grateful taste; and, though of a similar odour, is less agreeably fragrant. It is the kind almost universally kept in our shops, and, while it is much cheaper than the former variety, is perhaps not inferior to it for the preparation of the various tinctures, &c., into which cinnamon enters as an ingredient. Of a similar character is the cinnamon imported directly from various parts of the East Indies. But under the name of cassia are also brought to us very inferior kinds of cinnamon, collected from the trunks or large branches of the trees, or injured by want of care in keeping, and perhaps some derived from inferior species. It is said that cinnamon from which the oil has been distilled, is sometimes fraudulently mingled with the genuine. These inferior kinds are detected, independently of their greater thickness, and coarseness of fracture, by their deficiency in the peculiar sensible properties of the spice.

From the analysis made by Vauquelin, it appears that cinnamon contains a peculiar essential oil, tannin, mucilage, a colouring matter, an acid, and lignin. The oil obtained from the Cayenne cinnamon, he found to be more biting than that from the Ceylonese, and at the same time to be somewhat peppery. Bucholz found in 100 parts of *cassia lignea*, 0·8 of volatile oil, 4·0 of resin, 14·6 of gummy extractive (probably including tannin), 64·3 of lignin and bassorin, and 16·3 of water including loss. This aromatic yields its virtues wholly to alcohol, and less readily to water. At the temperature of boiling alcohol very little of the oil rises, and an extract prepared from the tincture retains, therefore, the aromatic properties. For an account of the essential oil, see *Oleum Cinnamomi*.

Medical Properties and Uses. Cinnamon is among the most grateful and efficient of the aromatics. It is warm and cordial to the stomach, carminative, astringent, and, like most other substances of this class, more powerful as a local than general stimulant. It is seldom, however, prescribed alone, though sometimes capable, when given in powder or infusion, of allaying nausea, checking vomiting, and relieving flatulence. It is chiefly used as an adjuvant to other less pleasant medicines, and enters into a great number of officinal preparations. It is peculiarly adapted to diarrhœa, and is often employed in that complaint with chalk and astringents. The dose of the powder is from ten grains to a scruple.

Cassia Buds. This spice was formerly recognised as officinal by the Edinburgh College, under the name of *Flores Lauri Cassiæ*, but has been omitted in their last Pharmacopœia. It consists of the calyx of one or more species of *Cinnamomum*, surrounding the young germ, and, as stated by Dr. Martius on the authority of the elder Nees, about one quarter of the normal size. It is produced in China; and Mr. Reeves states that great quantities of it are brought to Canton from the province which affords the cassia. The species which yields it is in all probability the same with that which yields the bark, though it has been ascribed by Nees to the *Cinnamomum Loureirii*. In favour of the former opinion is the statement of Dr. Christison, that the *C. aromaticum*, cultivated in the hot houses of Europe, bears a flower-bud which closely resembles the cassia-bud when at the same period of advancement. Cassia-buds have some resemblance to cloves, and are compared to small nails with round heads. The enclosed germen is sometimes removed, and they are then cup-shaped at top. They have a brown colour, with the flavour of cinnamon, and yield an essential oil upon distillation. Though little known in this country, they may be used for the same purposes as the bark.

COCCULUS. *Ed.**Cocculus Indicus.*

“Fruit of *Anamirta Cocculus*.” *Ed.*

Off. Syn. COCCULUS SUBEROSUS. *Fructus. Dub.*

Coque du Levant, Fr.; Kokkelskörner, Fischkörner, Germ.; Galla di Levante, Ital.

The plant which produces *Cocculus Indicus* was embraced by Linnæus, with several others, under the common title of *Menispermum Cocculus*. These were afterwards referred by De Candolle to a new genus, which he demominated *Cocculus*. From this the particular species under consideration has recently been separated by Wight and Arnott, and erected into a distinct genus with the name of *Anamirta*, which has been adopted by Lindley and other botanists.

ANAMIRTA. Sex. Syst. Diœcia Dodecandria.—*Nat. Ord.* Menispermaceæ.

Gen. Ch. Flowers diœcious. *Calyx* of six sepals in a double series, with two close-pressed bractioles. *Corolla* none. *MALE.* Stamens united into a central column dilated at the apex. *Anthers* numerous, covering the whole globose apex of the column. *FEMALE. Flowers* unknown. *Drupe* one to three, one-celled, one-seeded. *Seed* globose, deeply excavated at the hilum. *Albumen* fleshy. *Cotyledons* very thin, diverging. (*Wight and Arnott.*)

Anamirta Cocculus. Wight and Arnott, *Flor. Penins. Ind. Orient.* i. 446; Lindley, *Flor. Med.* 371.—*Menispermum Cocculus.* Linn.—*Cocculus Suberosus.* De Cand. *Prodrom.* i. 97. This is the only species. It is a climbing shrub, with a suberose or corky bark; thick, coriaceous, smooth, shining, roundish or cordate leaves, sometimes truncate at the base; and the female flowers in lateral compound racemes. It is a native of the Malabar coast, and of Eastern Insular and Continental India. The fruit is the official portion.

This plant was proved to be the source of *Cocculus Indicus* by Roxburgh, who raised it from genuine seeds which he had received from Malabar, and planted in the recent state. It is believed that other allied plants, bearing similar fruit, contribute to furnish the drug; and the *Cocculus Plukenetii* of Malabar, and *C. lacunosus* of Celebes and the Moluccas are particularly designated by authors. It was known to the Arabian physicians, and for a long time was imported into Europe from the Levant, from which circumstance it was called *cocculus Levanticus*. It is now brought exclusively from the East Indies.

Properties, &c. *Cocculus Indicus*, as found in the shops, is roundish, somewhat kidney-shaped, about as large as a pea; having a thin, dry, blackish, wrinkled exterior coat, within which is a ligneous bivalvular shell, enclosing a whitish, oily, very bitter kernel. It is without smell, but has an intensely and permanently bitter taste. It bears some resemblance to the bay berry, but is not quite so large, and may be distinguished by the fact that in the *Cocculus Indicus* the kernel never wholly fills the shell. When the fruit is kept long, the shell is sometimes almost empty. The Edinburgh College directs that “the kernels should fill at least two-thirds of the fruit.” M. Boullay discovered in the seeds a peculiar bitter principle which he demominated *picrotoxin*. This is white, crystallizable in quadrangular prisms, soluble in twenty-five parts of boiling and fifty of cold water, very soluble in alcohol and ether, but insoluble in the oils. It is poisonous, and, in the quantity of from five to ten grains given to strong dogs, produces death pre-

ceded by convulsions. To procure it, the watery extract of the seeds is triturated with pure magnesia, and then treated with hot alcohol, which dissolves the picrotoxin, and yields it upon evaporation. In this state, however, it is impure. To obtain it colourless it must be again dissolved in alcohol, and treated with animal charcoal. After filtration and due evaporation, it is deposited in the crystalline form. Besides picrotoxin, Cocculus Indicus contains a large proportion of fixed oil and some other substances of less interest. The active principle above described is said to reside exclusively in the kernel, upon which part M. Boullay operated. In the shell, MM. Pelletier and Couerbe discovered two distinct principles, one having alkaline properties and named *menispermin* (menispermia), the other identical with it in composition, but distinguishable by its want of alkalinity, its volatility, and its solubility and crystalline form, and denominated *paramenispermin*. They also found, in the same part, a new acid, which they called *hypo-picrotoxic*. The picrotoxin of M. Boullay they believed to possess acid properties, and, under this impression, proposed for it the name of *picrotoxic acid*. (*Journ. de Pharm.* xx. 122.)

Medical Properties, &c. Cocculus Indicus acts upon the system in the manner of the acrid narcotic poisons, but is never given internally. In India it is used to stupefy fishes in order that they may be caught; and it has been applied to the same purpose in Europe and this country. It is asserted that the fish thus taken are not poisonous. In Europe, it is said to be added to malt liquors in order to give them bitterness and intoxicating properties, although the practice is forbidden by the law, in England, under heavy penalties. The powdered fruit, mixed with oil, is employed in the East Indies as a local application in obstinate cutaneous affections. An ointment made with the powder has been used in tinea capitis and to destroy vermin in the hair. Picrotoxin has been successfully substituted by Dr. Jaeger for the drug itself. Rubbed up with lard in the proportion of ten grains to the ounce, it usually effected cures of tinea capitis in less than a month.

Cochineal.

“Coccus Cacti.” *U. S.*

Off. Syn. COCCI. Coccus Cacti. *Lond., Ed.*; COCCUS CACTI. *Dub.*

Cochenille, *Fr.*; Germ.; Cocciniglia, *Ital.*; Cochinilla, *Span.*

The Coccus is a genus of hemipterous insects, having the snout or rostrum in the breast, the antennæ filiform, and the posterior part of the abdomen furnished with bristles. The male has two erect wings, the female is wingless. The *C. Cacti* is characterized by its depressed, downy, transversely wrinkled body, its purplish abdomen, its short and black legs, and its subulate antennæ, which are about one-third of the length of the body. (*Rees's Cyclopædia*.)

This insect is found wild in Mexico and the adjoining countries, inhabiting different species of Cactus and allied genera of plants; and is said to have been discovered also in some of the West India islands, and the southern parts of the United States. In Mexico, particularly in the provinces of Oaxaca and Guaxaca, it is an important object of culture. The Indians form plantations of the *nopal* (*Opuntia cochinillefera*), upon which the insect

feeds and propagates. During the rainy season, a number of the females are preserved under cover upon the branches of the plant, and are distributed after the cessation of the rains upon the plants without. They perish very speedily after having deposited their eggs. These, hatched by the heat of the sun, give origin to innumerable minute insects, which spread themselves over the plant. The males, of which, according to Mr. Ellis, the proportion is not greater than one to one hundred or two hundred females, being provided with wings and very active, approach and fecundate the latter. After this period, the females, which before moved about, attach themselves to the leaves, and increase rapidly in size; so that, in the end, their legs, antennæ, and proboscis are scarcely discoverable, and they appear more like excrescences on the plant than distinct animated beings. They are now gathered for use, by detaching them from the plant by means of a blunt knife, a few being left to continue the race. They are destroyed either by dipping them enclosed in a bag into boiling water, or by the heat of a stove. In the former case they are subsequently dried in the sun. The males, which are much smaller than the full grown females, are not collected. It is said that of the wild insect there are six generations every year, furnishing an equal number of crops; but the domestic is collected only three times annually, the propagation being suspended during the rainy season, in consequence of its inability to support the inclemency of the weather. The insect has been taken from Mexico to the Canary Islands, where it has been successfully propagated; and considerable quantities of cochineal have been delivered to commerce from the island of Teneriffe. Attempts have also been made to introduce the culture into Spain, Corsica, and Algiers. (*Journ. de Pharm.* xxv. 592.)

As kept in the shops, the finer cochineal, *grana fina* of Spanish commerce, is in irregularly circular or oval somewhat angular grains, about one-eighth of an inch in diameter, convex on one side, concave or flat on the other, and marked with several transverse wrinkles. Two varieties of this kind of cochineal are known to the druggist, distinguished by their external appearance. One is of a reddish-gray colour, formed by an intermixture of the dark colour of the insect with the whiteness of a powder by which it is almost covered, and with patches of a rosy tinge irregularly interspersed. From its diversified appearance, it is called by the Spaniards *cochinilla jaspeada*. It is the variety commonly kept in our shops. The other, *cochinilla renegrada*, or *grana nigra*, is dark coloured, almost black, with only a minute quantity of the whitish powder between the wrinkles. The two are distinguished in our markets by the name of *silver grains* and *black grains*. Guibourt supposes the difference to depend upon the effect of culture, or, perhaps, on original varieties in the insect. According to others, it arises from the mode of preparation; the gray cochineal consisting of the insects destroyed by a dry heat; the black, of those destroyed by immersion in hot water, which removes the external whitish powder. There is little or no difference in their quality.

Another and much inferior variety is the *grana sylvestra* or wild cochineal, consisting partly of very small separate insects, partly of roundish or oval masses, which exhibit, under the microscope, minute and apparently new born insects, enclosed in a white or reddish cotton-like substance. It is scarcely known in our drug market.

Cochineal has a faint heavy odour, and a bitter slightly acidulous taste. Its powder is of a purplish carmine colour, tinging the saliva intensely red. According to Pelletier and Caventou, it consists of a peculiar colouring principle which they call *carmine*, a peculiar animal matter constituting the

skeleton of the insect, a fatty matter composed of stearin and oléin, an odorous fatty acid, and various salts. It was also analyzed by John, who called the colouring principle *cochinilin*. Carmine is of a brilliant purple red colour, unalterable in dry air, fusible at 122° F., very soluble in water, soluble in cold, and more so in boiling alcohol, insoluble in ether, and without nitrogen among its constituents. It is obtained by macerating cochineal in ether, and treating the residue with successive portions of boiling alcohol, which on cooling deposit a part of the carmine, and yield the remainder by spontaneous evaporation. It may be freed from a small proportion of fatty matter which adheres to it, by dissolving it in alcohol of 40° Baumé, and then adding an equal quantity of sulphuric ether. Pure carmine is deposited in the course of a few days. The watery infusion of cochineal is of a violet crimson colour, which is brightened by the acids, and deepened by the alkalies. The colouring matter of cochineal is readily precipitated. The salts of zinc, bismuth, and nickel produce a lilac precipitate, and those of iron a dark purple approaching to black. The salts of tin, especially the nitrate and chloride, precipitate the colouring matter of a brilliant scarlet, and form the basis of those splendid scarlet and crimson dyes, which have rendered cochineal so valuable in the arts. With alumina the colouring matter forms the pigment called *lake*. The finest *lakes* are obtained by mixing the decoction of cochineal with freshly prepared gelatinous alumina. The pigment called *carmine* is the colouring matter of cochineal precipitated from the decoction by acids, the salts of tin, &c., or animal gelatin, and when properly made is of the most intense and brilliant scarlet.

Cochineal has been adulterated by causing certain heavy substances, by shaking in a bag or otherwise, to adhere to the surface of the insects, and thus increase their weight. The fraud may be detected by the absence, under the microscope, of a woolly appearance which characterizes the white powder upon the surface of the unadulterated insect.

Medical Properties, &c. Cochineal is supposed by some to possess anodyne properties, and has been recommended in hooping cough and neuralgic affections; but it is little used internally. In pharmacy it is employed to colour tinctures and ointments.

The dose of a tincture prepared by macerating one part of cochineal in eight parts of diluted alcohol, is for an adult from twenty to thirty drops twice a day. In neuralgic paroxysms, Sauter gave half a tablespoonful, with the asserted effect of curing the disease.

COCHLEARIA OFFICINALIS. *Herba. Dub.*

Common Scurvy-grass.

Cranson, *Herbe aux cuillers, Fr.*; Löffelkraut, *Germ.*; Coclearia, *Ital., Span.*

COCHLEARIA. See ARMORACIA.

Cochlearia officinalis. Willd. *Sp. Plant.* iii. 448; Woodv. *Med. Bot.* p. 393. t. 112. The common scurvy-grass is an annual or biennial plant, sending up early in the spring a tuft of radical leaves, which are heart-shaped, roundish, of a deep shining green colour, and supported on long footstalks. The leaves of the stem are alternate, oblong, somewhat sinuate, the lower petiolate, the upper sessile. The stem is erect, branched, angular, six or eight inches high, and bears, at the extremity of the branches, nume-

rous white cruciform peduncled flowers, in thick clusters. The fruit is a roundish two-celled pod, containing numerous seeds. The whole plant is smooth and succulent.

It is a native of the northern countries of Europe, where, as well as in the United States, it is occasionally cultivated in gardens. The whole herb is officinal. It has, when fresh, a pungent unpleasant odour if bruised, and a warm, acrid, bitter taste. These properties are lost by drying. They are imparted to water and alcohol by maceration, are retained by the expressed juice, and probably depend on a peculiar volatile oil which is separable in very small quantity by distillation with water.

Medical Properties and Uses. Common scurvy-grass is gently stimulant, aperient, and diuretic. It is highly celebrated as a remedy in sea scurvy; and has been recommended in chronic obstructions of the viscera, and certain forms of chronic rheumatism. The fresh plant may be eaten as a salad, or used in the form of infusion in water or wine, or of the expressed juice. Alcohol and water are impregnated with its virtues by distillation, and the distilled spirit has been found useful in paralysis in the dose of thirty drops several times a day. The expressed juice may be used as a local application in scorbutic affections of the gums. W.

COLCHICUM. Sex. Syst. Hexandria Trigynia.—Nat. Ord. Melanthaceæ.

Gen. Ch. A spathe. Corolla six-parted, with a tube proceeding directly from the root. Capsules three, connected, inflated. Willd.

Colchicum autumnale. Willd. Sp. Plant. ii. 272; Woodv. Med. Bot. p. 759. t. 258. This species of *Colchicum*, often called *meadow-saffron*, is a perennial bulbous plant, the leaves of which appear in spring, and the flowers in autumn. Its manner of growth is peculiar, and deserves notice in this place, as connected in some measure with its medicinal efficacy. In the latter part of summer, a new bulb, or *cormus* as botanists now call the part, begins to form at the lateral inferior portion of the old one, which receives the young offshoot in its bosom, and embraces it half round. The new plant sends out fibres from its base, and is furnished with a radical spathe, which is cylindrical, tubular, cloven at top on one side, and half under ground. In September, from two to six flowers, of a lilac or pale purple colour, emerge from the spathe, unaccompanied with leaves. The corolla consists of a tube five inches long, concealed for two-thirds of its

length in the ground, and of a limb divided into six segments. The flowers perish by the end of October, and the rudiments of the fruit remain under ground till the following spring, when they rise upon a stem above the surface in the form of a three-lobed, three-celled capsule. The leaves of the new plant appear at the same time, so that in fact they follow the flower instead of preceding it, as might be inferred from the order of the seasons in which they respectively show themselves. The leaves are radical, spear-shaped, erect, numerous, about five inches long, and one inch broad at the base. In the mean time, the new bulb has been increasing at the expense of the old, which having performed its appointed office perishes, while the former, after attaining its full growth, sends forth new shoots from itself, and in its turn decays. Each parent bulb has two offsets.

The *C. autumnale* is a native of the temperate parts of Europe, where it grows wild in moist meadows. Various attempts have been made to introduce its culture into this country, but with no very encouraging success; though small quantities of the bulb of apparently good quality have been brought into the market. The officinal portions are the bulb or cormus, and the seeds. The root, botanically speaking, consists of the fibres which are attached to the base of the bulb. The flowers have been found to possess similar virtues with the bulb and seeds, but have not been adopted in the Pharmacopœias.

1. COLCHICI RADIX.

The medicinal virtue of the bulb depends much upon the season at which it is collected. Early in the spring it is too young to have fully developed its peculiar properties; and late in the fall it has become exhausted by the nourishment which it has afforded to the new plant. The proper period for its collection is from the early part of June, when it has usually attained perfection, to the middle of August, when the offset appears. It is probably owing, in great measure, to this inequality in the colchicum at different seasons, that entirely opposite reports have been given by different authors of its powers. Krapf ate whole bulbs without experiencing inconvenience; Haller found it entirely void of taste and acrimony; and we are told that in Carniola the peasants use it as food with impunity in the autumn. On the contrary, abundant testimony might be adduced of its highly irritating and poisonous nature, of which in fact there exists at present no doubt. Perhaps soil and climate may have some influence in modifying its character.

The meadow-saffron bulb is often used in the fresh state in the countries where it grows, as it is apt to be injured in drying, unless the process is very carefully conducted. The usual plan is to cut the bulb, as soon after it has been dug up as possible, into thin transverse slices, which are spread out separately upon paper or perforated trays, and dried with a moderate heat. The reason for drying it very speedily after removal from the ground, is that it otherwise begins to vegetate, and a change in its chemical nature takes place; and such is its retentiveness of life, that if not cut in slices, it is liable to undergo a partial vegetation even during the drying process. It sustains much loss of weight by exsiccation. Mr. Bainbridge obtained only two pounds fifteen ounces of dried bulb from eight pounds of the fresh.

Properties. The recent bulb or cormus of the *C. autumnale* resembles that of the tulip in shape and size, and is covered with a brown membranous coat. Internally it is solid, white, and fleshy; and when cut transversely, yields, if mature, an acrid milky juice. Dr. J. R. Coxe lays much stress on a small lateral projection from its base, which serves in his opinion to distinguish it from all other bulbs; but which appears to be merely a con-

necting process between it and the new plant, and is not always present. When dried and deprived of its external membranous covering, the bulb is of an ash-brown colour, convex on one side, and somewhat flattened on the other, where it is marked by a deep groove extending from the base to the summit. As found in our shops it is always in the dried state, sometimes in segments made by vertical sections of the bulb, but generally in transverse circular slices, about the eighth or tenth of an inch in thickness, with a notch at one part of their circumference. The cut surface is white, and of an amylaceous aspect. The odour of the recent bulb is said to be *hirvine*; the dried is inodorous. The taste is bitter, hot, and acrid. Its constituents, according to Pelletier and Caventou, are a peculiar vegetable alkali denominated *veratria*,* combined with an excess of gallic acid; a fatty matter composed of olein, stearin, and a peculiar volatile acid analogous to the cevadic; a yellow colouring matter; gum; starch; inulin in large quantity; and lignin. The active properties are ascribed to the *veratria*, for an account of which see *Veratrum album*. Wine and vinegar extract all the virtues of the bulb. Dr. A. T. Thomson informs us that the milky juice of fresh colchicum produces a beautiful cerulean blue colour, if rubbed with the alcoholic solution of guaiac; and that the same effect is obtained by substituting for the juice an acetic solution of the dried bulb. He considers the appearance of this colour, when the slices are rubbed with a little distilled vinegar and tincture of guaiac, as a proof that the drug is good and has been well dried. A very deep or large notch in the circumference of the slices is considered by the same author an unfavourable sign, as it indicates that the bulb has been somewhat exhausted in the nourishment of the offset. The decoction yields a deep blue precipitate with solution of iodine, white precipitates with the acetates of lead, nitrate of protoxide of mercury, and nitrate of silver, and a slight precipitate with tincture of galls.

Medical Properties and Uses. Meadow-saffron is believed to act upon the nervous system, allaying pain and producing other sedative effects, even when it exerts no obvious influence over the secretions. Generally speaking, when taken in doses sufficiently large to affect the system, it gives rise to more or less disorder of the stomach or bowels, and sometimes occasions active vomiting and purging, with the most distressing nausea. When not carried off by the bowels, it often produces copious diaphoresis, and occasionally acts as a diuretic and expectorant; and a case is on record of a violent salivation supposed to have resulted from its use. (*N. Am. Med. and*

* According to Geiger and Hesse, the organic alkali of the meadow-saffron is peculiar, and entirely distinct from *veratria*, with which it has been confounded. They propose for it the name of *colchicine*, which, in accordance with our nomenclature, should be changed to *colchicia*. It is crystallizable, and has a very bitter and sharp taste, but is destitute of the extreme acrimony of *veratria*, and does not, like that principle, excite violent sneezing when applied to the nostrils. It differs also in being more soluble in water, and less poisonous in its influence on the animal system. To a kitten eight weeks old, one-tenth of a grain was given dissolved in a little dilute alcohol. Violent purging and vomiting were produced, with apparently severe pain and convulsions, and the animal died at the end of twelve hours. The stomach and bowels were found violently inflamed, with effusion of blood throughout their whole extent. A kitten somewhat younger was destroyed in ten minutes by only the twentieth of a grain of *veratria*; and, on examination after death, marks of inflammation were found only in the upper part of the œsophagus. We do not know that the conclusions of Geiger and Hesse have yet been confirmed by other experimentalists. The process for obtaining *colchicia* is similar to that employed in the preparation of hyoscyamia from hyoscyamus. (*See the Article Hyoscyamus*.) A simpler process is to digest the seeds of meadow-saffron in boiling alcohol, precipitate the tincture with magnesia, treat the precipitated matter with boiling alcohol, and finally filter and evaporate.

Surg. Journ. x. 204.) It appears in fact to have the property of stimulating all the secretions, while it rather diminishes than otherwise the action of the heart. In an overdose, it is capable of producing dangerous and even fatal effects. Excessive nausea and vomiting, abdominal pains, purging and tenesmus, sinking of the pulse, coldness of the extremities, and general prostration, with occasional symptoms of nervous derangement, are among the results of its poisonous action. It was well known to the ancients as a poison, and is said to have been employed by them as a remedy in gout and other diseases. Störck revived its use among the moderns. He gave it as a diuretic and expectorant in dropsy and humoral asthma; and on the continent of Europe it acquired considerable reputation in these complaints; but the uncertainty of its operation led to its general abandonment, and it had fallen into almost entire neglect, when Dr. Want of London again brought it into notice, by attempting to prove its identity with the active ingredient of the *eau medicinale d'Husson*, so highly celebrated as a cure for gout. The chief employment of the meadow-saffron is at present in the treatment of gout and rheumatism, in which experience has abundantly proved it to be a highly valuable remedy. We have, within our own observation, found it especially useful in these affections, when of a shifting or neuralgic character. It sometimes produces relief without obviously affecting the system; but is more efficient when it evinces its influence upon the skin or alimentary canal. Professor Chelius states that it changes the chemical constitution of the urine in arthritic patients, producing an evident increase of the uric acid. (*N. Am. Med. and Surg. Journ.* xi. 234.) This effect, however, is by no means uniform. Dr. Elliotson successfully treated a case of prurigo with the wine of colchicum, given in the dose of half a drachm three times a day, and continued for three weeks. (*Medico-Chirurg. Rev.* Oct. 1827.) Dr. Smith, of Port au Prince, employed it advantageously in tetanus both traumatic and idiopathic. He gave it in full doses repeated every half hour till it produced an emetic or cathartic effect. (*Am. Journ. of the Med. Sci.* xvii. 66.) Mr. Ritton found the powdered bulb an effectual remedy in numerous cases of leucorrhœa. (*Ibid.* vi. 527.) Colchicum has also been recommended in inflammatory and febrile diseases as an adjuvant to the lancet, in diseases of the heart with excessive action, in various nervous complaints, as chorea, hysteria, and hypochondriasis, and in chronic bronchial affections. The medicine is generally given in the state of vinous tincture. (See *Vinum Colchici Radicis*.) In this form it has been used externally in rheumatism. The dose of the dried bulb is from two to eight grains, which may be repeated every four or six hours till the effects of the medicine are obtained.

2. COLCHICI SEMEN.

The seeds of the meadow-saffron ripen in summer, and should be collected about the end of July or beginning of August. They never arrive at maturity in plants cultivated in a dry soil, or in confined gardens. (*Williams*.) They are nearly spherical, about the eighth of an inch in diameter, of a reddish-brown colour externally, white within, and of a bitter acrid taste. Their active properties reside in the testa or husk, and they should not, therefore, be bruised in the preparation of the wine or tincture.* Dr.

* The following description of the seeds is given by Mr. Gray in the *Lond. Med. Re-*

Williams of Ipswich in England, who first brought them into notice, recommends them in the warmest terms in chronic rheumatism, and considers them superior to the bulb, both in the certainty of their effects and the mildness of their operation. There is no doubt that they possess virtues analogous to those of the bulb, and have this advantage, that they are not liable to become injured by drying—an advantage of peculiar value in a country where the plant is not cultivated, and where the bulb cannot be readily procured in the fresh state. A wine of the seeds is directed in the United States Pharmacopœia. Their dose is about the same with that of the bulb.

Cucumis Colocynthis. Willd. *Sp. Plant.* iv. 611; Woodv. *Med. Bot.* p. 189. t. 71. The bitter cucumber is an annual plant, bearing considerable resemblance in appearance to the common cucumber of our gardens. The stems, which are herbaceous and beset with rough hairs, trail upon the ground, or rise upon neighbouring bodies to which they attach themselves by their numerous tendrils. The leaves are of a triangular shape, many-cleft, variously sinuated, obtuse, hairy, of a fine green colour on the upper surface, rough and pale on the under; and stand alternately upon long petioles. The flowers are yellow, and appear singly at the axils of the leaves. The fruit is a globular pepo, of the size of a small orange, yellow and smooth when ripe; and contains, within a hard coriaceous rind, a white spongy medullary matter, enclosing numerous ovate, compressed, white or brownish seeds.

The plant is a native of Turkey, and abounds in the islands of the Archipelago. It grows also in various parts of Africa and Asia. Burkhart, in his travels across Nubia, found the country covered with it; Thunberg met with it at the Cape of Good Hope; and Ainslie says that it grows in many parts of Lower India, particularly in sandy situations near the sea. It is said to be cultivated in Spain.

The fruit is gathered in autumn, when it begins to assume a yellow colour, pository for April, 1821. “*Seeds*, ovate, globose, about one-eighth of an inch in diameter. *Integuments*, simple, soft, spongy, membranaceous, thin, reddish-brown, closely adherent to the perisperm. *Perisperm* or *albumen*, hard, rather cartilaginous, pellucid, pale, not in the least divided, of the same shape as the seed. *Corculum* or *embryo*, very small, ovate globose, not in the least divided, whitish, placed nearly opposite to the *hylum*, or that part where the seed is affixed to the parent plant, but out of the axis of the seed. Base pointing to the *hylum*, slender. Apex very obtuse.” An acquaintance with the real characters of the seeds is the more necessary, as the seeds of other plants have been sold for them.

and, having been peeled, is dried quickly either in a stove or by the sun. Thus prepared it is imported from the Levant. Pereira states that very small quantities are imported into England from Mogadore unpeeled.

Properties. As kept in the shops, colocynth is in the shape of whitish balls, about the size of a small orange, very light and spongy, and abounding in seeds which constitute three-fourths of their whole weight. The seeds are somewhat bitter; but possess comparatively little activity, and, according to Captain Lyon, are even used as food in Northern Africa. When the medicine is prepared for use, they are separated and rejected, the pulpy or medullary matter only being employed. This has a very feeble odour, but a nauseous and intensely bitter taste. Water and alcohol extract its virtues. Vauquelin obtained the bitter principle in a separate state, and called it *colocynthin*. According to the analysis of Meissner, 100 parts of the dry pulp of colocynth contain 14.4 parts of colocynthin, 10.0 of extractive, 4.2 of fixed oil, 13.2 of a resinous substance insoluble in ether, 9.5 of gum, 3.0 of pectic acid (pectin), 17.6 of gummy extract derived from the lignin by means of potassa, 2.7 of phosphate of lime, 3.0 of phosphate of magnesia, and 19.0 of lignin, besides water. (*Berzelius, Trait. de Chim.*) Colocynthin is obtained by boiling the pulp in water, evaporating the decoction, treating the extract thus procured with alcohol, evaporating the alcoholic solution, and submitting the residue, which consists of the bitter principle and acetate of potassa, to the action of a little cold water, which dissolves the latter, and leaves the greater part of the former untouched. It is of a yellowish-brown colour, somewhat translucent, brittle and friable, inflammable, more soluble in alcohol than in water, but capable of imparting to the latter an intense bitterness. The aqueous solution gives with the infusion of galls an abundant white precipitate. An infusion of colocynth, made with boiling water, has a golden-yellow colour, and gelatinizes upon cooling. Neumann obtained from 768 parts of the pulp, treated first with alcohol and afterwards with water, 168 parts of alcoholic and 216 of aqueous extract.

Medical Properties and Uses. The pulp of colocynth is a powerful drastic, hydragogue cathartic, producing, when given in large doses, violent griping, and sometimes bloody discharges, with dangerous inflammation of the bowels. Death has resulted from a teaspoonful and a half of the powder. (*Christison.*) Even in moderate doses it sometimes acts with much harshness, and is therefore seldom prescribed alone. By some writers it is stated to be diuretic. It was frequently employed by the ancient Greeks and the Arabians, though its drastic nature was not unknown to them. Among the moderns it is occasionally used, especially by the German practitioners, in obstinate cases of dropsy, and various affections depending on disordered action in the brain. In combination with other cathartics it loses much of its violence, but retains its purgative energy; and in this state is very extensively employed. The compound extract of colocynth is a favourite preparation with many practitioners; and combined with calomel, extract of jalap, and gamboge, it forms a highly efficient and safe cathartic, especially applicable in congestion of the portal circle and torpidity of the liver. (See *Pilulæ Catharticæ Compositæ*.) The dose of colocynth is from five to ten grains. It is best administered in a state of minute division effected by trituration with gum or farinaceous matter.

Thunberg states that the fruit of the *C. Colocynthis*, at the Cape of Good Hope, is rendered so mild by being properly pickled, that it is eaten both by the natives and colonists; but as it is thus employed before attaining perfect

maturity, it is possible that the drastic principle may not have been developed.

Colombo, Fr.; Columbowurzel, *Germ.*; Columba, *Ital.*; Rafz de Columbo, *Span.*; Kalumbo, *Port.*; Calumb, *Mozambique.*

The columbo plant has been, till a recent period, but imperfectly known to botanists. Flowering specimens of a plant gathered by Commerson, about the year 1770, in the garden of M. Poivre in the Isle of France, and sent to Europe with that botanist's collection, were examined by Lamarck, and described under the name of *Menispermum palmatum*. But its original locality was unknown, and it was only conjecturally supposed to be the source of columbo. In the year 1805, M. Fortin, while engaged in purchasing the dried root as an article of trade in Mozambique, obtained possession of a living offset, which he took to Madras, and which, being planted in the garden of Dr. Anderson, produced a male plant. This was figured and described by Dr. Berry, without any knowledge of the previous description of Lamarck. From the drawing thus made, the plant was referred to the natural family of the Menispermæ; but, as the female flowers were wanting, some difficulty was experienced in fixing its precise botanical position. De Candolle, who probably had the opportunity of examining Commerson's specimens, did indeed give its generic and specific character; but confessed that he was not acquainted with the structure of the female flower and fruit. The desideratum, however, has been recently supplied by ample drawings sent to England by Mr. Telfair, of Mauritius, made from plants which were propagated from living roots, obtained by Captain Owen in 1825, while prosecuting his survey of the Eastern coast of Africa. (See *Curtis's Botan. Mag. vol. 4. pl. 2970.*) The genus *Cocculus* of De Candolle, in which the plant is now placed, was separated by that botanist from the genus *Menispermum*, and includes those species which have six stamens, while the *Menispermum* is limited to those with twelve or more.

Cocculus. *Sex. Syst.* Diœcia Hexandria.—*Nat. Ord.* Menispermaceæ.

Cocculus palmatus. *De Cand. Syst. Veg. i. 523; Woodv. Med. Bot. 3d Ed. vol. 5. p. 21.* This is a climbing plant, with a perennial root, consisting of several fasciculated, fusiform, somewhat curved, and descending tubers, of the thickness of an infant's arm. The stems, of which one or two proceed from the same root, are twining, simple in the male plant, branched in the female, round, hairy, and about as thick as the little finger. The leaves, which stand on rounded, glandular-hairy footstalks, are alternate, distant, cordate, with three, five, or seven entire, acuminate, wavy, somewhat hairy lobes, and as many nerves, each of which runs into one of the

lobes. The flowers are small and inconspicuous, and are arranged in solitary axillary racemes, which, in the male plant, are compound, in the female, simple, and in both shorter than the leaves.

This species of *Cocculus* is a native of Mozambique, on the south-eastern coast of Africa, where it grows wild in great abundance in the thick forests which extend from the sea many miles into the interior. The plant is never cultivated. The root is dug up in March, when dry weather prevails. From the base of the root numerous fusiform offsets proceed, less fibrous and woody than the parent stock. These offsets are separated and cut into transverse slices, which are dried in the shade. The old root is rejected.

Columbo is a staple export of the Portuguese from their dominions in the South East of Africa. It is taken to India, and thence distributed to various parts of the world. It was formerly supposed to be a product of Ceylon, and to have derived its name from Colombo, a city of that island, from which it was thought to be exported. It is possible that, when the Portuguese were in possession of Ceylon, Colombo may have been the entrepot for the drug brought from Africa, and thus have given origin to its name. Some, however, consider a more probable derivation to be from the word *calumb*, which is said to be the Mozambique name for the root.

Properties. The root, as it reaches us, is in flat circular or oval pieces, from the eighth of an inch to near an inch in thickness, and from one to two inches in diameter. Along with these are sometimes a few cylindrical pieces an inch or two in length. The cortical portion is thick, of a bright yellow slightly greenish colour internally, but covered with a brownish wrinkled epidermis. The interior or medullary portion, which is readily distinguishable from the cortical, is light, spongy, yellowish, usually more or less shrunk, so that the pieces are thinnest in the centre; and is frequently marked with concentric circles and radiating lines. Those pieces are to be preferred which have the brightest colour, are most compact and uniform in their texture, and are most free from the worm-holes by which the root is apt to be penetrated. The odour of columbo is slightly aromatic. The taste is very bitter, that of the cortical much more so than that of the central portion, which is somewhat mucilaginous. The root is brittle, and easily pulverized. The powder has a greenish tinge, which becomes browner with age and deepens when it is moistened. As it attracts moisture from the air, and is apt to undergo decomposition, it should be prepared in small quantities at a time.

M. Planché analyzed columbo in 1811, and found it to contain a peculiar azotized substance in large quantity, a bitter yellow substance not precipitated by metallic salts, and one-third of its weight of starch. He obtained also a small proportion of essential oil, salts of lime and potassa, oxide of iron, and silica. Mr. Wittstock of Berlin has subsequently isolated a peculiar crystallizable principle, in which the bitterness resides, and for which he proposes the name of *colombin*. (*Journ. de Pharm. Fevrier, 1831.*) It appears to be the bitter yellow substance of Planché, deprived of a portion of colouring matter. *Colombin* crystallizes in beautiful transparent quadrilateral prisms, is without smell, and is extremely bitter. It is but very slightly soluble in water, alcohol, or ether, at ordinary temperatures, and yet imparts to these fluids a strongly bitter taste. It is more soluble in boiling alcohol, which deposits it upon cooling. The best solvent is diluted acetic acid. It is taken up by alkaline solutions, from which it is precipitated by acids. It has neither acid nor alkaline properties, and its alcoholic and acetic solutions are not affected by the metallic salts, or the infusion of galls. The

process for obtaining it consists in exhausting columbo by means of alcohol of the sp. gr. 0.835, distilling off three quarters of the alcohol, allowing the residue to stand for some days till crystals are deposited, and lastly treating these crystals with alcohol and animal charcoal. The mother-waters still contain a considerable quantity of colombin, which may be separated by evaporating with coarsely powdered glass to dryness, exhausting the residue with ether, distilling off the ether, treating the residue with boiling acetic acid, and evaporating the solution so that crystals may form. Colombin is thought to be the active principle of columbo, but is probably somewhat modified in its action on the system by the other substances with which it is associated. The virtues of the root are extracted by boiling water and by alcohol. Precipitates are produced with the infusion and tincture by the infusion of galls, the acetate and subacetate of lead, corrosive chloride of mercury, and lime-water; but the bitter principle is not affected by these reagents.

Adulterations. In France, a spurious columbo was some years since extensively substituted for the genuine root, which, according to Guibourt, had become rare in the commerce of that country. As it may possibly be introduced into our market, it is desirable that our druggists should be put in possession of the characters by which it may be distinguished. Though similar to columbo in appearance, it is different in properties, and is therefore truly a sophistication. It is said to be taken to France from Barbary; but the plant which yields it is not known. Though in round slices like the genuine root, it has an epidermis of a gray-fawn colour, marked with close and parallel circular striæ; its transverse surfaces are irregularly depressed; the medullary portion is of a yellowish-orange, with a deeper coloured circle; the smell is weak like that of gentian, the taste feebly bitter and rather saccharine; the powder is of a yellow-fawn instead of a greenish colour; but the most striking difference is the total absence of starch, which constitutes one-third of columbo. Iodine therefore is an excellent test. If the true columbo be moistened with hot water, and touched with iodine, it immediately assumes a blackish colour; while the spurious root, treated in the same way, undergoes no change. The latter differs also in communicating a fine yellow colour to ether, in evolving ammonia when treated with caustic potassa, and in reddening in infusion the tincture of litmus.

It is said that the root of white bryony, tinged yellow with the tincture of columbo, has sometimes been fraudulently substituted; but the adulteration is too gross to deceive those acquainted with the characters of either of these drugs.

The American columbo, the root of the *Frasera Walteri*, is said to be sold in some parts of Europe for the genuine. Independently of the sensible differences between the two roots, (see *Frasera*.) M. Stolze of Halle states, that while the tincture of columbo remains unaffected by the sulphate or sesquichloride of iron, and gives a dirty gray precipitate with tincture of galls, the tincture of frasera acquires a dark green with the former reagent, and is not affected by the latter. (*Duncan*.)

Medical Properties and Uses. Columbo is among the most useful of the mild tonics. Without astringency, with very little stimulating power, and generally acceptable to the stomach, it answers admirably as a remedy in simple dyspepsia, and in those states of debility which are apt to attend convalescence from acute disorders, especially when the alimentary canal is left in an enfeebled condition. Hence it is often prescribed in the declining stages of remittent fever, dysentery, diarrhœa, cholera morbus, and cholera infantum. The absence of irritating properties renders it also an appro-

prate tonic in the hectic fever of phthisis, and its kindred affections. It has been highly recommended in vomiting, unconnected with inflammation of the stomach, as in the sickness of pregnant women. It is frequently administered in combination with other tonics, with aromatics, with mild cathartics, and with antacids. The remedy which we have found most effectual in the permanent cure of a disposition to the accumulation of flatus in the bowels, is an infusion made with half an ounce of columbo, half an ounce of ginger, a drachm of senna, and a pint of boiling water, and given in the dose of a wineglassful three times a day. Columbo is much used by the natives of Mozambique, and the neighbouring parts of Africa, in dysentery and other diseases. (*Berry*.) It was first introduced to the notice of the profession in Europe by François Redi, in the year 1685.

It is most commonly prescribed in the state of infusion. (*See Infusum Colombæ*.) The dose of the powder is from ten to thirty grains, and may be repeated three or four times a day. It is frequently combined with powdered ginger, carbonate of iron, and rhubarb.

Gen. Ch. *Partial Involucre* halved, usually three-leaved. *Fruit* nearly globular, five-streaked, notched on both sides. *Willd.*

Conium maculatum. Willd. *Sp. Plant.* i. 1395; Bigelow, *Am. Med. Bot.* i. 113; Woodv. *Med. Bot.* p. 104. t. 42. This is an umbelliferous plant, having a biennial spindle-shaped whitish root, and an herbaceous branching stem, from three to six feet high, round, hollow, smooth, shining, slightly striated, and marked with brownish-purple spots. The lower leaves are tripinnate, more than a foot in length, shining, and attached to the joints of the stem by sheathing petioles; the upper are smaller, bipinnate, and inserted at the divisions of the branches; both have channeled foot-stalks, and incised leaflets which are deep green on their upper surface and paler beneath. The flowers are very small, white, and disposed in compound terminal umbels. The general involucre consists of from three to seven lanceolate, reflected leaflets, whitish at their edges; the partial involucre, of three or four, oval, pointed, spreading, and on one side only. The petals are cordate, with their points inflected, five in number, and nearly equal. The stamens are spreading, and about as long as the corolla; the styles diverging. The

fruit is roundish ovate, a line and a half or rather less in length by a line in breadth, striated, and composed of two plano-convex, easily separable parts, which have on their outer surface five crenated ribs.

The hemlock is a native of Europe, and has been introduced into the United States, where it is now naturalized. It grows usually in bunches along the road sides or in waste grounds, and is found most abundantly in the neighbourhood of old settlements. Its flowers appear in June and July. The whole plant, especially at this period, exhales a fetid odour, compared by some to that of mice, by others to that of the urine of cats; and narcotic effects are experienced by those who breathe for a long time air impregnated with the effluvia. The plant varies in narcotic power according to the climate and character of the weather, being most active in hot and dry seasons, and in warm countries. The hemlock of Greece, Italy, and Spain is said to be much more energetic than that of the North of Europe. As a general rule, those plants are most active which grow in a sunny exposure. The term *cicuta*, which till recently was very often applied to this plant, belongs to a different genus. Both the leaves and fruit are official.

The proper season for gathering the leaves is when the plant is in flower; and Dr. Fothergill asserts from experimental knowledge, that they are most active about the time when the flowers begin to fade. The footstalks should be rejected, and the leaflets quickly dried, either in the hot sun, on tin plates before a fire, or by a stove heat not exceeding 120° F. They should be kept in boxes or tin cases, excluded as much as possible from the air and light, by exposure to which they lose their fine green colour, and become deteriorated in medical virtues. The same end is answered by pulverizing them, and preserving the powder in opaque and well stopped bottles. But little reliance can be placed on the dried leaves; as, even when possessed of a strong odour and a fine green colour, they are sometimes destitute of the peculiar narcotic principle. When rubbed with caustic potassa they should exhale the odour of conia. The fruit, commonly called seeds, retains its activity much longer than the leaves.

Properties. The dried leaves of the hemlock have a strong, heavy, narcotic odour, less disagreeable than that of the recent plant. Their taste is bitterish and nauseous; their colour a dark green, which is retained in the powder. A slight degree of acrimony possessed by the fresh leaves is said to be dissipated by drying. The seeds have a yellowish-gray colour, a feeble odour, and a somewhat bitterish taste. Their form has already been described. Water distilled from the fresh leaves has the odour of hemlock, and a very nauseous taste, but does not produce narcotic effects upon the system. The decoction has little taste, and the extract resulting from its evaporation is nearly inert. From these facts it is inferrible that the active principle, as it exists in the plant, is not volatile at 212°, and, if soluble in water, is injured by a boiling heat. Alcohol and ether take up the narcotic properties of the leaves; and the ethereal extract, which is of a rich dark green colour, is stated by Dr. A. T. Thomson to have the smell and taste of the plant in perfection, and in the dose of half a grain to produce headache and vertigo. Upon destructive distillation, the leaves yield a very poisonous empyreumatic oil. We have no satisfactory analysis of hemlock. Schrader found in the juice of the leaves, resin, extractive, gum, albumen, a green fecula, and various saline substances. Brandes obtained from the plant a very odorous oil, albumen, resin, colouring matter, and salts, and believed that he had discovered a peculiar alkaline principle; but there is good reason to think that he was mistaken; as the principle which he described is essen-

tially different from that which subsequent experiment has proved to exist in the plant.

So long ago as 1827, Giseke obtained an alkaline liquid by distilling hemlock leaves with water and caustic lime; but he did not succeed in isolating the substance in which this alkalinity resided. Geiger was undoubtedly the first who obtained the active principle in a separate state, and proved it to possess alkaline properties. It appears that there are two volatile substances in hemlock, one of them an *oil*, which comes over by simple distillation, and upon which the odour of the plant depends, and the other an *alkaline principle*, which, as it exists in the plant, is so combined as not to be volatilizable, but which, when separated by one of the mineral alkalies from its native state of combination, rises readily in distillation, and may thus be procured separate. This latter substance is the active principle of the plant, and merits the name of *conia* which has been conferred upon it. *Conëine*, *conine*, *conicine*, and *cicutine* are synonymes, which have been adopted by different writers; but the name first mentioned is that which accords with the nomenclature of the vegetable alkalies generally recognised in England and this country. What is the state of combination in which it exists in the plant is not certainly known; but it is probably united with an acid, as it may be separated by the reaction of the alkalies. This acid Peschier believed to be peculiar, and named *coniic acid*. Geiger obtained *conia* by the following process. He distilled fresh hemlock with caustic potassa and water, neutralized with sulphuric acid the alkaline liquid which came over, evaporated this liquid to the consistence of syrup, added anhydrous alcohol so long as a precipitate of sulphate of ammonia was afforded, separated this salt by filtration, distilled off the alcohol, mixed the residue with a strong solution of caustic potassa, and distilled anew. The *conia* passed over with the water, from which it separated, floating on the surface in the form of a yellowish oil. Caustic soda or lime might be substituted for potassa in the first distillation. According to Dr. Christison, an easier process is to distil cautiously a mixture of strong solution of potassa and the alcoholic extract of the unripe fruit. The alkaloid is obtained floating like an oil upon the surface of the water in the receiver. As obtained by the above processes, *conia* is in the state of a hydrate, containing one-fourth of its weight of water and a little ammonia. From the former, it may be freed by chloride of calcium, from the latter, by exposing it under an exhausted receiver till it ceases to emit bubbles of gas.

The fresh leaves or seeds should be employed in the preparation of *conia*; as the alkali appears to undergo decomposition by time and exposure. The seeds contain most of this principle; but even in these it exists in very small proportion. From six pounds of the fresh and nine pounds of the dried seeds, Geiger obtained about an ounce of *conia*; while from one hundred pounds of the fresh herb he got only a drachm, and from the dried leaves could obtain none of the alkali. Christison recommends the full grown fruit while yet green; and states that eight pounds will yield half an ounce of hydrate of *conia*, and contains much more. (*Dispensatory*.) Some doubts were at one time thrown upon the accuracy of Geiger's conclusions as to the nature of *conia*, which was supposed to owe its alkalinity to the presence of ammonia; but the experiments of MM. Boutron and Henry have satisfactorily settled the question in favour of its claims to be considered as a peculiar organic alkali.

Conia is in the form of a yellowish, oily liquid, lighter than water, of a strong and penetrating odour, recalling that of fresh hemlock yet not identical with it, and of a very acrid taste. In volatility it resembles the essen-

al oils, readily rising with the vapour of boiling water, but when unmixed, requiring for ebullition, according to Christison, a temperature of 370° . It is freely soluble in alcohol, ether, the fixed and volatile oils, and slightly so in water. It unites with about one-fourth of water to form a hydrate. It reddens turmeric, and neutralizes the acids, forming with them soluble salts, some of which are crystallizable. With tannic acid it forms an insoluble compound. Like ammonia it emits a white cloud, when approached by a cold moistened with muriatic acid. When exposed to the air, it speedily becomes of a deep brown colour, and is ultimately converted into a resinous matter, and into ammonia which escapes. Under the influence of heat this change takes place with much greater rapidity. Its presence may be detected in an extract or other preparation of hemlock by rubbing it with potassa, which instantly develops its peculiar odour. In ultimate composition it is analogous to the other organic alkalies, containing oxygen, hydrogen, carbon, and nitrogen. In its effects on the system it closely resembles hemlock itself. Dr. Christison found it, contrary to the experience of Geiger, even more active in the saline state, than when uncombined. It is a most energetic poison, one drop of it injected into the eye of a rabbit killing the animal in nine minutes, and three drops killing a stout rat in a minute and a half when similarly applied. Dr. Christison, from whose paper these facts are derived, (*Trans. Ed. Roy. Soc.* 1836,) is of the opinion that it acts upon the spinal marrow, directly prostrating the nervous power, and thus producing paralysis of the voluntary muscles, which, invading the organs of respiration, destroys life by arresting this process. The brain does not seem to be especially attacked, as the animal, when it lies slowly, preserves its senses unimpaired so long as it breathes. In cases of sudden death from the poison, the heart does not cease to act till after apparent death; and its action may be sustained after the animal has ceased to breathe by keeping up artificial respiration. Experiments made upon animals with a recently prepared extract of hemlock produced precisely the same phenomena as those which followed the use of conia. Locally the alkali appears to act as an irritant.

Medical Properties and Uses. Hemlock is narcotic, without being decidedly stimulant or sedative to the circulation. Mr. Judd, however, has inferred from his experiments that it directly diminishes the action of the heart, and when it produces death, contrary to the results obtained by Christison, exhausts the contractility of that organ. (*Medico-Bot. Trans.* vol. i. pt. 4.) These conclusions require confirmation. When given so as fully to affect the system it produces more or less vertigo, dimness of vision, nausea, faintness, and general muscular debility. In larger doses it occasions dilated pupils, difficulty of speech, delirium or stupor, tremors and paralysis, and ultimately convulsions and even death. Its operation usually commences in less than half an hour, and if moderate seldom continues longer than twenty-four hours. It is supposed to be the narcotic used by the Athenians to destroy the life of condemned individuals, and by which Socrates and Phocion died. It was also used by the ancients as a medicine, but fell into entire neglect; and was not again brought into notice till the time of Störck, by whom it was much employed and extravagantly praised. Since that period it has been submitted to ample trial, and, though its original reputation has not been fully sustained, it still retains a place in the catalogue of useful medicines. Anodyne, soporific, antispasmodic, antaphrodisiac, deobstruent, and diuretic properties have been ascribed to it; though its claims to the possession of so many virtues have not been well established. It was highly recommended by Störck as a remedy in scir-

thus and cancerous ulcers, but at present is only considered a useful palliative in this complaint. In mammary tumours and chronic enlargements of the liver and other abdominal viscera; in painful serofulous tumours and ulcers; in various diseases of the skin, as leprosy and elephantiasis; in the complicated derangement of health attendant upon secondary syphilis; in chronic rheumatism and neuralgic affections; in excessive secretion of milk; in pertussis, asthma, chronic catarrh, and consumption; and in various other disorders connected with nervous derangement, or a general depraved state of the health, it is occasionally employed with the effect of relieving or palliating the symptoms, or favourably modifying the action of remedies with which it is combined. Dr. Gibson, professor of Surgery in the University of Pennsylvania, speaks highly of its efficacy in the cure of goitre. (See *Phil. Journ. of the Med. and Phys. Sci.* i. 67.)

The powdered leaves, and the inspissated juice (the extract of the Pharmacopœias), are the forms in which it is usually administered. Either of these may be given in the dose of three or four grains twice a day, gradually increased till the occurrence of slight vertigo or nausea indicates that it has taken effect. To maintain a given impression, it is necessary to increase the dose even more rapidly than is customary with most other narcotics; as the system becomes very speedily habituated to its influence. In some instances, the quantity administered in one day has been augmented to more than two ounces. The strength of the preparations of hemlock is exceedingly unequal; and caution is therefore necessary, when the medicine is given in very large quantities, to employ the same parcel, or, if a change be made, to commence with the new parcel in small doses, so as to obviate any danger which might result from its greater power. Unpleasant consequences have resulted from a neglect of this precaution. There is also an officinal tincture and an alcoholic extract, both of which, when properly prepared, are efficient preparations. The fresh juice of the plant has been recommended by Hufeland in the dose of from twelve to forty drops. The powdered seeds may be employed in a dose somewhat smaller than that of the leaves. Cullen states that an extract prepared from them is stronger than that of the plant. The fresh leaves are sometimes used externally as an anodyne cataplasm; and the extract, and an ointment prepared from the leaves are applied to the same purpose.

Though fatal to some animals, hemlock is eaten with impunity by others, as horses, goats, and sheep. The best method of relieving its poisonous effects, is the speedy evacuation of the stomach.

CONTRAYERVA. *U. S. Secondary.*

Contrayerva.

“The root of *Dorstenia Contrayerva*.” *U. S.*

Off. Syn. CONTRAJERVA. *Dorstenia Contrajerva*. Radix. *Lond.*

Contrayerva, *Fr.*; Giftwurzel, *Germ.*; Contrajerva, *Ital.*; Contrayerba, *Span.*

DORSTENIA. *Sex. Syst.* Tetrandria Monogynia.—*Nat. Ord.* Urticacæ.

Gen. Ch. Receptacle common, one-leaved, fleshy, in which solitary seeds are nestled. *Willd.*

The root known by the name of *contrayerva* is believed to be derived from several species of *Dorstenia*, among which, besides the *D. Contra-*

yerva, two others are mentioned by Dr. Houston, the *D. Houstonia*, and *D. Drakena*, the former growing near Campeachy, the latter near Vera Cruz. It is referred by Dr. Martius also to the *D. Brasiliensis*, growing in Jamaica, Trinidad, and Brazil. The *D. Contrayerva* is the only one recognised in the Pharmacopœias.

Dorstenia Contrayerva. Willd. *Sp. Plant.* i. 682; Woodv. *Med. Bot.* p. 705. t. 240. This plant has a perennial, fusiform, branching, rough, compact root or rhizoma, which sends up several leaves of an irregular shape, about four inches in length, lobed, serrated, pointed, and placed upon long radical footstalks, which are winged towards the leaves. The scapes or flower-stems are also radical, rise several inches in height, and support irregular quadrangular receptacles, which contain male and female flowers, the former having two stamens, the latter a single style. The capsule, when ripe, possesses an elastic power, by which the seeds are thrown out with considerable force.

The plant grows in Mexico, the West Indies, and Peru. The root (rhizoma) is the officinal portion. According to Pereira, however, the *contrayerva* of the shops is not the product of the species above described, but of the *D. Brasiliensis*, and is brought from Brazil. The term *contrayerba*, in the language of the Spanish Americans, signifies *counterpoison* or *antidote*, and was applied to this root under the impression that it has the property of counteracting all kinds of poison.

Properties. The root, as found in our shops, is oblong, an inch or two in length, of varying thickness, very hard, rough, and solid, of a reddish-brown colour externally, and pale within; and has numerous long, slender, yellowish fibres attached to its inferior part. The odour is aromatic; the taste warm, slightly bitterish, and pungent. The fibres have less taste and smell than the tuberous portion. The sensible properties are extracted by alcohol and boiling water. The decoction is of a dark, brownish-red colour, and highly mucilaginous. The tincture reddens infusion of litmus, and lets fall a precipitate on the addition of water. The root has not yet been analyzed, but is known to contain starch and a volatile oil.

Medical Properties and Uses. *Contrayerva* is a stimulant tonic and diaphoretic, and has been given in low states of fever, malignant eruptive diseases, some forms of dysentery and diarrhœa, and other diseases requiring gentle stimulation. It is very seldom used in this country. The dose of the powdered root is about half a drachm. W.

CONVOLVULUS PANDURATUS. U.S. Secondary.

Wild Potato.

“The root of *Convolvulus panduratus*.” U.S.

CONVOLVULUS. See SCAMMONIUM.

Convolvulus panduratus. Willd. *Sp. Plant.* i. 850; Barton, *Med. Bot.* i. 249. The wild potato has a perennial root, and a round, purplish, procumbent or climbing stem, which twines around neighbouring objects, and grows sometimes twelve feet in length. The leaves, which stand alternately on long petioles, are broad, heart-shaped at the base, entire, or lobed on the sides like a guitar or violin, somewhat acuminate, deep green on the upper surface, and paler beneath. The flowers are in fascicles upon long axillary peduncles. The calyx is smooth and awnless; the corolla, tubular campanulate, very large, white at the border, but purplish-red at the base.

The plant is indigenous, growing throughout the United States in sandy

fields, and along fences, and flowering from June to August. A variety with double flowers is cultivated in the gardens for the sake of ornament.

The root, which is the officinal part, is very large, two or three feet in length, about three inches thick, branched at the bottom, externally of a brownish-yellow colour and full of longitudinal fissures, internally whitish and milky, and of a somewhat acrid taste. Pursh says that he has seen a root as thick as a man's thigh.

Medical Properties. The wild potato is feebly cathartic, and has been proposed as a substitute for jalap, but is scarcely used. It is thought also to be somewhat diuretic, and has been employed, with supposed advantage, in strangury and calculous complaints. Forty grains of the dried root are said to purge gently. Perhaps an extract might be found more effectual.

COPAIBA. U.S., Lond., Ed.

Copaiba.

"The juice of *Copaifera officinalis* and other species of *Copaifera*." U. S. "*Copaifera Langsdorffii*. *Resina liquida*." Lond. "Fluid resinous exudation of various species of *Copaifera*. *Copaiva*." Ed.

Off. Syn. COPAIFERA OFFICINALIS. *Resina liquida*. Dub.

Balsam of Copaiba; Baume de copahu, Fr.; Copaiva-Balsam, Germ.; Balsamo di copaiba, Ital.; Balsamo de copayva, Span.

COPAIFERA. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Leguminosæ, *Jussieu*. Amyridaceæ, *Lindley*.

Gen. Ch. Calyx none. Petals four. Legume ovate. Seed one, with an ovate arillus. Willd.

The first notice to be found of the copaiba plant is that by Maregrav and Piso, in the year 1648. Jacquin in 1763 described a species of *Copaifera*, which grew in the island of Martinique, and which he named *C. officinalis*, from the fact that it afforded this resinous juice. As this was believed to be the same plant with that observed by Maregrav in Brazil, it was adopted without hesitation in the Pharmacopœias; but their identity is now denied; and Desfontaines has proposed for the officinal species the title of *C. Jacquini*, in honour of the botanist who originally described it. From recent observation and discoveries it appears, that numerous species of *Copaifera* exist in Brazil and other parts of South America, all of which, according to Martius, yield copaiba. Besides the *C. officinalis* or *C. Jacquini*, the following are described by Hayne;—*C. Guianensis*, *C. Langsdorffii*, *C. coriacea*, *C. Beyrichii*, *C. Martii*, *C. bijuga*, *C. nitida*, *C. laxa*, *C. cordifolia*, *C. Jussieu*, *C. Sellowii*, *C. oblongifolia*, and *C. multijuga*. Hayne believes that the *C. bijuga* is the plant seen by Maregrav and Piso.

Copaifera officinalis. Willd. ii. 630; Woodv. *Med. Bot.* p. 609. t. 216. *C. Jacquini*. Desfont. *Mem. du Mus.* vii. 376; Hayne, *Darstel. und Beschreib.* &c. x. 14. 'This is an elegant tree, with a lofty stem, much branched at the top, and crowned by a thick canopy of foliage. The leaves are alternate, large, and pinnate, composed of from two to five pairs of ovate, entire, obtusely acuminate leaflets, two or three inches in length, rather narrower on one side than the other, smooth, pellucidly punctate, somewhat shining, and supported on short footstalks. The flowers are whitish, and disposed in terminal branched spikes. The fruit is an oval, two-valved pod, containing a single seed.

This species of *Copaifera* is a native of Venezuela, and grows in the pro-

vince of Carthagena, mingled with the trees which afford the balsam of Tolu. It grows also in some of the West India islands, particularly Trinidad and Martinique, where it is said to be naturalized. Though recognised in the United States Pharmacopœia as the source of the officinal copaiba, it probably yields little of that now in use. According to Hayne, the species from which most of the Copaiba of commerce is derived, is the *C. multi-juga*, growing in the province of Para. It is probable that the *C. Guianensis*, which inhabits the neighbouring province of Guiana, especially in the vicinity of the Rio Negro, affords also considerable quantities; and the *C. Langsdorffii* and *C. coriacea*, which are natives of Santo Paulo, are thought to yield most of the juice collected in the last mentioned province. But the London College is certainly in error in ascribing copaiba exclusively to the *C. Langsdorffii*; as little of that found in commerce is derived from the region of country where that species is known to flourish.

The juice is obtained by making deep incisions into the stems of the trees; and the operation is said to be repeated several times in the same season. As it flows from the wound, it is clear, colourless, and very thin, but soon acquires a thicker consistence, and a yellowish tinge. It is most largely collected in the provinces of Para and Maranham, in Brazil, and until recently was brought to this country chiefly from the port of Para, in small casks or barrels. But large quantities of it are now brought from Maracaybo, in Venezuela, and from other ports on the Caribbean sea, whence it comes in casks, demijohns, cans, jugs, &c. Copaiba is also exported from the French South American province of Cayenne, from Rio Janeiro, and from some of the West India islands; but little reaches the United States from these sources.

Properties. Copaiba is a clear, transparent liquid, usually of the consistence of olive oil, of a pale yellow colour, a peculiar not unpleasant odour, and a bitterish, hot, nauseous taste. Its specific gravity varies from 0.950 to 1.000. It is insoluble in water, but entirely soluble in absolute alcohol, ether, and the fixed and volatile oils. Strong alkaline solutions dissolve it perfectly; but the resulting solution becomes turbid when largely diluted with water. With the alkalies and alkaline earths, it forms saponaceous compounds, in which the resin of the copaiba appears to act the part of an acid. It dissolves magnesia, especially with the aid of heat, and even disengages carbonic acid from the carbonate of that earth. If triturated with a sixteenth of its weight of magnesia and set aside, it gradually assumes a solid consistence; and a similar change is produced with hydrate of lime. (See *Pilulæ Copaibæ*.) Its essential constituents are volatile oil and resin, with a minute proportion of an acid which appears to be the acetic. (Durand. *Journ. of the Phil. Col. of Pharm.* i. 3.) As it contains no benzoic acid, it cannot with propriety retain its former title of *balsam of copaiba*. The substances which it most closely resembles, both in composition and properties, are the turpentine.

The *volatile oil*, which has been adopted as officinal by the Edinburgh College under the name of *COPAIBÆ OLEUM*, constitutes from a third to one-half or more of the copaiba. It may be separated by distillation, and is best obtained by distillation with water. As it first comes over it is colourless, but the later product is of a fine greenish hue. By redistillation it may be rendered wholly colourless. It has the odour and taste of copaiba, is lighter than water, boils at about 470° (*Christison*), is soluble in ether and alcohol, absorbs muriatic acid gas and forms with it crystals of artificial camphor, and when pure contains no oxygen, being isomeric with pure oil of turpentine. It answers even better than naphtha for preserving potassium, a fact first observed by Mr. Durand of Philadelphia.

The *resinous* mass which remains is hard, brittle, translucent, of a greenish-brown colour, and nearly destitute of smell and taste. By mixing it with the oil in proper proportion, we may obtain a liquid identical or nearly so with the original juice. When treated with the oil of petroleum, it is separated into two distinct resins, one of which is dissolved, and may be obtained separate by evaporation, the other is left behind. The first is yellowish, hard, and brittle, and constitutes by far the largest proportion of the residuum of the distillation. It appears to possess acid properties; as its alcoholic solution reddens litmus, and it forms definite compounds with the alkalies. It has therefore received the name of *copaivic acid*. The second resin is yellowish-brown, soft, unctuous, and without acid reaction; and is supposed by Berzelius to result from the resinification of the volatile oil, as it is more abundant in the old than in the recent juice. Recent copaiba examined by Gerber yielded 41 per cent. of volatile oil, 51·38 of the hard and brittle resin, 2·18 of the soft resin, and 5·44 of water; while an older specimen gave 31·07 per cent. of oil, 53·68 of hard resin, 11·15 of soft resin, and 4·10 of water.

Copaiba, upon exposure to the air, assumes a deeper colour, a thicker consistence, and greater density, and if spread out upon an extended surface, ultimately becomes dry and brittle. This change is owing partly to the volatilization, partly to the oxidation of the essential oil. Considerable diversities must, therefore, exist in the drug, both in physical properties and the proportion of its ingredients, according to its age and degree of exposure. Similar differences also exist in the copaiba procured from different sources. Thus, that of the *West Indies*, when compared with the *Brazilian*, which is the variety above described and in common use, is of a thicker consistence, of a deeper or darker yellow colour, less transparent, and of a less agreeable, more terebinthinate odour; specimens obtained from the ports of Venezuela or New Grenada were found upon examination by M. Vigne, to differ from each other not only in physical properties, but also in their chemical relations (*Journ. de Pharm. N. S.* i. 52.); and it is not impossible that differences may exist in the juice according to the circumstances of its collection.

Adulterations. Copaiba is said to be frequently adulterated; but the remark is applicable rather to the markets of Europe than to those of the United States. The fixed oils are the most frequent addition, especially castor oil, which, in consequence of its solubility in alcohol, cannot, like the others, be detected by the agency of this fluid. Various plans have been proposed for ascertaining the presence of castor oil. The simplest is to boil one drachm of the copaiba in a pint of water, till the liquid is wholly evaporated. If the copaiba contain oil, the residue will be more or less soft according to the quantity present; otherwise it will be hard. Another mode, proposed by M. Planche, consists in shaking together in a bottle one part of solution of ammonia of the sp. gr. 0·9212 (22° Baumé) with two and a half parts of copaiba, at a temperature of from 50° to 60° F. The mixture, at first cloudy, quickly becomes transparent if the copaiba is pure, but remains more or less opaque if it is adulterated with castor oil. Carbonate of magnesia, caustic potassa, and sulphuric acid have also been proposed as tests. In the *Edinburgh Pharmacopœia*, it is stated that copaiba “dissolves a fourth part of its weight of carbonate of magnesia, with the aid of a gentle heat, and continues translucent.” The presence of a small proportion of any fixed oil renders the mixture opaque. Turpentine, which is said to be sometimes added to copaiba, may be detected by its smell, especially if the copaiba be heated.

Medical Properties and Uses. Copaiba is gently stimulant, diuretic, laxative, and in very large doses often actively purgative. It produces, when swallowed, a sense of heat in the throat and stomach, and extends an irritant action, not only throughout the alimentary canal, but also to the urinary passages, and in fact, in a greater or less degree, to all the mucous membranes, for which it appears to have a strong affinity. The urine acquires a peculiar odour during its use, and its smell may be detected in the breath. It sometimes occasions an eruption upon the skin, resembling that of measles, and attended with a disagreeable itching and tingling sensation. Nausea and vomiting, painful purgation, strangury and bloody urine, and a general state of fever are among the morbid results of its excessive action. As a remedy it has been found most efficient in the diseases of the mucous membranes, particularly such as are of a chronic character. Thus it is given with occasional advantage in leucorrhœa, gleet, chronic dysentery, painful hemorrhoidal affections, and in chronic catarrh and other forms of bronchial disease. By Dr. La Roche, of Philadelphia, it is highly recommended in catarrh of the bladder, and in chronic irritation of the same organ. (*Am. Journ. of Med. Scien.* xiv. 13.) It has been given with some success in dropsy; and is said to be used as a vermifuge in Brazil. The complaint, however, in which it is most employed is gonorrhœa. It is given in all stages of the disorder; but caution is requisite when the inflammatory symptoms are high. Even in health, if taken largely, it sometimes produces very unpleasant irritation of the urinary passages, and, by sympathy, of the testicles. It was formerly highly esteemed as a vulnerary, and as an application to ulcers; but is now seldom used externally. Dr. Ruschenberger, of the U. S. navy, strongly recommends it as a local application in chilblains. (*Med. Examiner*, i. 77.)

The dose of copaiba is from twenty drops to a fluidrachm three times a day, or a smaller quantity repeated more frequently. It may be given dropped on sugar; but in this form is often so exceedingly offensive, as to render some concealment of its nauseous qualities necessary. It is sometimes given floating on the surface of some aromatic water, or mixed with an equal measure of spirit of nitric ether. A less disagreeable form is that of emulsion, prepared by rubbing the copaiba first with mucilage or the yolk of an egg, and sugar, and afterwards with water impregnated with some aromatic essential oil, as that of mint or cinnamon. The *volatile oil* may be used in the dose of ten or fifteen drops, and probably with the same effects as the copaiba, of which it is the active ingredient. It may be administered dropped on sugar, or in the form of emulsion. The resin, which has been proposed as a substitute, is nearly inert. The pills made by means of magnesia may sometimes be resorted to with advantage; and it has recently become the fashion to administer copaiba enclosed in capsules of gelatin, which completely cover the taste, while they are readily dissolved in the liquors of the stomach. (See *Glue*, in the *Appendix*.) Velpeau has found the best effects from copaiba in the form of enema. He gives two drachms made into an emulsion with the yolk of an egg, twenty or thirty drops of laudanum, and eight fluidounces of water.

COPTIS. U.S. Secondary.

Goldthread.

"The root of *Coptis trifolia*." U.S.

COPTIS. *Sex. Syst.* Polyandria Polygynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. *Calyx* none. *Petals* five or six, caducous. *Nectaries* five or six, cucullate. *Capsules* five to eight, stipitate, stellately diverging, and rostrate, many-seeded. *Nuttall*.

Coptis trifolia. Bigelow, *Am. Med. Bot.* i. 60; Barton, *Med. Bot.* ii. 97. This little evergreen bears considerable resemblance to the strawberry in size and general aspect. It has a perennial creeping root, which, from its slenderness, and bright yellow colour, has given rise to the name of *goldthread*, by which the plant is commonly known. The caudex, from which the petioles and flower-stems proceed, is invested with ovate, acuminate, yellowish, imbricated scales. The leaves, which stand on long slender footstalks, are ternate, with firm, rounded or obovate, sessile leaflets, having an acute base, a lobed and acuminately crenate margin, and a smooth veined surface. The scape or flower-stem is slender, round, rather longer than the leaves, and surmounted by one small white flower, with a minute mucronate bracte beneath it. The petals are oblong, concave, and of a white colour; the nectaries inversely conical, hollow, and yellow at the top. The stamens have capillary filaments and globose anthers. The germs are from five to eight, stipitate, oblong, compressed, and surmounted by short recurved styles, with acute stigmas. The capsules, which diverge in a star-like form, are pedicelled, compressed, beaked, and contain numerous black seeds attached to the inner side.

The goldthread inhabits the northern regions of this continent and of Asia, and is found in Greenland and Iceland. It delights in the dark shady swamps and cold morasses of northern latitudes and Alpine regions, and abounds in Canada, and in the hilly districts of New England. Its blossoms appear in May. All parts of the plant possess more or less bitterness; but this property is most intense in the root, which is the only portion directed by the Pharmacopœia.

Dried goldthread, as brought into the market, is in loosely matted masses, consisting of the long, thread-like, orange-yellow roots, frequently interlaced, and mingled with the leaves and stems of the plant. It is without smell, and has a purely bitter taste, unattended with aroma or astringency. It imparts its bitterness and yellow colour to water and alcohol, but most perfectly to the latter, with which it forms a bright yellow tincture. Its virtues appear to depend on a bitter extractive matter, which is precipitated by nitrate of silver and acetate of lead. (*Bigelow*.) It affords no evidence of containing either resin, gum, or tannin.

Medical Properties and Uses. It is a simple tonic bitter, bearing a close resemblance to quassia in its mode of action, and applicable to all cases in which that medicine is prescribed; though, from its higher price, not likely to come into general use as a substitute. In New England it is much employed as a local application in aphthous ulcerations of the mouth; but it probably has no other virtues in this complaint than such as are common to all the simple bitters. It may be given internally in substance, infusion, or tincture. The dose of the powder is from ten to thirty grains, of a tincture prepared by macerating an ounce of the root in a pint of diluted alcohol, one fluidrachm.

Another species of *Coptis* has been described by Dr. Wallich, under the name of *Coptis Teeta*, which grows in the mountainous regions bordering on Assam, and is much used as a tonic by the people of that country and by the Chinese. It appears to be closely analogous in properties to the *C. trifolia*. (*Am. Journ. of Pharm.* ix. 196.) W.

CORIANDRUM. U.S., Lond., Ed.

Coriander.

“The fruit of *Coriandrum sativum*.” *U. S.*, *Ed.* “*Coriandrum sativum*. *Fructus*.” *Lond.*

Coriandre, Fr.; *Koriander, Germ.*; *Coriandro, Ital.*; *Cilantro, Span.*

CORIANDRUM. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Apiaceæ or Umbelliferæ.

Gen. Ch. Corolla radiate. Petals inflex-emarginate. Universal involucre one-leaved. Partial involucre halved. Fruit spherical. *Willd.*

Coriandrum sativum. *Willd. Sp. Plant.* i. 1448; *Woodv. Med. Bot.* p. 137. t. 53. This is an annual plant, with an erect, round, smooth, branching stem, which rises about two feet in height, and is furnished with compound leaves, of which the upper are thrice ternate, with linear pointed leaflets, the lower pinnate, with the pinnæ cut into irregular serrated lobes, resembling those of common parsley. The flowers are white or rose-coloured, and disposed in compound terminal umbels. The fruit is globular, and consists of two concave hemispherical portions.

The *C. sativum* is a native of Italy, but at present grows wild in most parts of Europe, having become naturalized in consequence of its extensive cultivation. The flowers appear in June, and the fruit ripens in August. It is a singular fact, that all parts of the fresh plant are extremely fetid when bruised, while the fruit becomes fragrant by drying. This is the officinal portion. It is brought to us from Europe.

The fruit of the coriander, as found in the shops, is globular, about the eighth of an inch in diameter, obscurely ribbed, of a grayish or brownish-yellow colour, and separable into the two portions (half-fruits) of which it consists. It has the persistent calyx at its base, and is sometimes surmounted by the adhering style. The smell and taste are gratefully aromatic, and depend on a volatile oil, which may be obtained separate by distillation. They are imparted to alcohol by maceration, and less readily to water.

Medical Properties and Uses. Coriander has, in a moderate degree, the ordinary medical virtues of the aromatics. It is almost exclusively employed in combination with other medicines, either to cover their taste, to render them acceptable to the stomach, or to correct their griping qualities. It was well known to the ancients. The dose is from a scruple to a drachm.

CORNU. *Lond., Ed.**Hartshorn.*

“*Cervus Elaphus. Cornu.*” *Lond.* “Horn of *Cervus Elaphus.*” *Ed.*
Off. Syn. CORNUA CERVINA. Ramenta. Dub.

Corne de cerf, Fr.; Hirschhorn, Germ.; Corno di cervo, Ital.; Cuerno de ciervo, Span.

The stag or hart—*Cervus Elaphus*—the horns of which are directed by the British Colleges, inhabits Europe, Asia, and the North of Africa. Those of our own common deer—*Cervus Virginianus*—though employed in the arts, are not officinal. Hartshorn is usually imported into this country from Germany, in the state of shavings, but is very little employed.

Hartshorn shavings are without smell and taste, pliable, and of an ivory yellow colour. According to M. Merat-Guillot, they contain in 100 parts, 27 of gelatin, 57.5 of phosphate of lime, 1 of carbonate of lime, and 14.5 of water including the loss. Boiling water extracts their gelatin, forming a transparent, colourless jelly, which may be rendered palatable by the addition of sugar, lemon or orange juice, and a little wine. In its preparation, two pints of water are boiled with four ounces of the shavings to a pint, and the residue strained while hot. The clear liquid gelatinizes upon cooling. By destructive distillation, the shavings yield an impure solution of carbonate of ammonia, which formerly received the name of *spirit of hartshorn*; and the same name has been subsequently applied to similar ammoniacal solutions procured from other sources. When burnt, they leave an earthy residue consisting almost exclusively of phosphate of lime.

Medical Properties, &c. The jelly prepared from the shavings of hartshorn has been thought to possess medical virtues; but it is only nutritive and demulcent, and is probably not superior to calfsfoot jelly. The shavings themselves are used in the preparation of the Pulvis Antimonialis.

CORNUS CIRCINATA. *U.S. Secondary.**Round-leaved Dogwood.*

“The bark of *Cornus circinata.*” *U. S.*

CORNUS. Sex. Syst. Tetrandria Monogynia.—Nat. Ord. Cornaceæ.

Gen. Ch. Involucre usually four-leaved. *Petals* superior, four. *Drupe* with a two-celled nut. *Willd.*

We have ten indigenous species of *Cornus*, all of which are supposed to possess similar medical properties; and three—the *C. Florida*, *C. circinata*, and *C. sericea*—are noticed in the Pharmacopœia of the United States. The last two are placed in the secondary list, not because they are esteemed less efficient than the first; but because they have hitherto less attracted the attention of the profession.

Cornus circinata. Willd. Sp. Plant. i. 663. This is a shrub from six to ten feet high, with warty branches, large, roundish, pointed leaves, waved on their edges and downy beneath, and white flowers disposed in depressed cymes. The fruit is blue. The plant is a native of the United States, extending from Canada to Virginia, and growing on hill-sides and the banks of rivers. It flowers in June and July.

The bark, when dried, is in quills of a whitish or ash colour, and affords

a powder resembling that of ipecacuanha. Its taste is bitter, astringent, and aromatic. In chemical composition, so far as this has been ascertained, it is analogous to the *Cornus Florida*. It possesses also similar medical virtues, and may be employed in the same doses. It has been much used as a tonic and astringent in Connecticut, and was highly extolled by the late Dr. Ives of New York, who recommended, as the most eligible preparation, an infusion made by pouring a pint of boiling water on an ounce of the coarsely powdered bark. The dose of this is from one to two fluidounces. W.

CORNUS FLORIDA. U.S.

Dogwood.

“The bark of *Cornus Florida*.” U. S.

CORNUS. See CORNUS CIRCINATA.

Cornus Florida. Willd. *Sp. Plant.* i. 661; Bigelow, *Am. Med. Bot.* ii. 73; Barton, *Med. Bot.* i. 44. This is a small indigenous tree, usually about fifteen or twenty feet in height, though sometimes not less than thirty or thirty-five feet. It is of slow growth; and the stem, which generally attains a diameter of four or five inches, is compact, and covered with a brownish bark, the epidermis of which is minutely divided by numerous superficial cracks or fissures. The branches are spreading, and regularly disposed, sometimes opposite, sometimes in fours nearly in the form of crosses. The leaves are opposite, oval, about three inches long, pointed, dark green, and sulcated on the upper surface, glaucous or whitish beneath, and marked with strong parallel veins. Towards the close of summer they are speckled with black spots, and on the approach of cold weather assume a red colour. The proper flowers are small, yellowish, and collected in heads, which are surrounded by a very large conspicuous involucre, consisting of four white obcordate leaves, having the notch at their summit tinged with red or purple. It is this involucre that constitutes the chief beauty of the tree at the period of flowering. The calyx is four-toothed, and the corolla composed of four obtuse reflexed petals. The fruit is an oval drupe of a vivid glossy red colour, containing a two-celled and two-seeded nucleus. The drupes are usually collected to the number of three or four, and remain on the tree till after the early frosts. They ripen in September.

The dogwood is found in all parts of the United States, from Massachusetts to the Mississippi and the Gulf of Mexico; but is most abundant in the Middle States. In the month of May it is clothed with a profusion of large white blossoms, which render it one of the most conspicuous ornaments of the American forests. The bark is the officinal portion, and is derived for use both from the stem and branches, and from the root. The bark of the root is preferred. It is brought into market in pieces of various sizes, usually more or less rolled, sometimes invested with a fawn-coloured epidermis, sometimes partially or wholly deprived of it, of a reddish-gray colour, very brittle, and affording, when pulverized, a grayish powder tinged with red. The odour of dogwood is feeble, its taste bitter, astringent, and slightly aromatic. Water and alcohol extract its virtues. It has not been accurately analyzed; but, from the experiments of Dr. Walker and others, appears to contain extractive matter, gum, resin, tannin, and gallic acid. A peculiar bitter principle, for which the name of *cornine* has been proposed, has been announced as an ingredient by Mr. Carpenter; but we need more definite information on the subject. The flowers of the *C. Florida* have the same

bitter taste as the bark, and, though not officinal, are sometimes employed for the same purposes.

Medical Properties and Uses. *Cornus Florida* is tonic and astringent. By Dr. Walker it was found, when taken internally, to augment the force and frequency of the pulse, and increase the heat of the body. It is thought to possess remedial properties closely analogous to those of Peruvian bark, for which it has occasionally been successfully substituted in the treatment of intermittent fevers; but the introduction of sulphate of quinia into use has nearly banished this, as well as many other substitutes for cinchona, from regular practice. The dogwood has also been employed with supposed benefit in typhoid fevers, and other complaints for which the Peruvian tonic is usually prescribed.

It may be given in powder, decoction, or extract. The dose of the powder is from a scruple to a drachm, repeated in cases of intermittent fever, so that from one to two ounces may be taken in the interval between the paroxysms. The decoction is officinal. (See *Decoctum Cornus Floridae*.) The dried bark is said to be preferable to the fresh; as it possesses all the activity of the latter, without being equally liable to offend the stomach and bowels. An extract might probably be used with advantage in intermittents in large doses.

Off. Prep. *Decoctum Cornus Floridae. U. S.* W.

CORNUS SERICEA. U.S. Secondary.

Swamp Dogwood.

“The bark of *Cornus sericea*.” *U. S.*

CORNUS. See CORNUS CIRCINATA.

Cornus sericea. Willd. *Sp. Plant.* i. 663; Barton, *Med. Bot.* i. 115. This species of *Cornus* is usually six or eight feet in height, with numerous erect stems, which are covered with a shining reddish bark, and send out opposite spreading branches. The young shoots are more or less pubescent. The leaves are opposite, petiolate, ovate, pointed, entire, and on the under surface covered with soft brownish hairs. The flowers are small, white, and disposed in terminal cymes, which are depressed and woolly. The fruit consists of globular, berry-formed drupes, of a cerulean blue colour, and collected in bunches.

The swamp dogwood inhabits the United States from Canada to Carolina, and is found in moist woods, in swamps, and on the borders of streams. It flowers in June and July. The bark was ascertained by Dr. Walker to have the same medical properties with that of the *Cornus Florida*. It may be given in the same doses, and administered in a similar manner. W.

COTULA. U.S. Secondary.

May-weed.

“The herb of *Anthemis Cotula*.” *U. S.*

Camomille puante, Maroute, *Fr.*; *Hunds-Kamille*, *Stinkende-Kamille*, *Germ.*; *Camomilla fetida*, *Cotula*, *Ital.*; *Manzanilla loca*, *Span.*

ANTHEMIS. See ANTHEMIS.

Anthemis Cotula. Willd. *Sp. Plant.* iii. 2181; Barton, *Med. Bot.* i. 161. The May-weed is an annual plant, with a fibrous root, and an erect striated stem, very much branched even to the bottom, from one to two feet in

height, and supporting alternate, sessile, flat, doubly pinnated, somewhat hairy leaves, with pointed linear leaflets. The flowers stand singly upon the summits of the branches, and consist of a central, convex, golden-yellow disk, with white radial florets, which spread horizontally during the day, but are reflexed or bent towards the stem at night. The calyx, which is common to all the florets, is hemispherical, and composed of imbricated hairy scales. The receptacle is conical or nearly cylindrical, and surmounted by rigid, bristle-shaped paleæ, shorter than the florets. The seeds are naked.

This plant grows abundantly both in the United States and in Europe. In this country, it is found in the vicinity of inhabited places, growing among rubbish, along the sides of roads, and in waste grounds. Notwithstanding its extensive diffusion, it is generally believed to be a naturalized, not an indigenous plant. It is frequently called *wild chamomile*. It flowers from the middle of summer till late in autumn.

The whole plant has a strong, disagreeable smell, and a warm, bitter taste, and imparts these properties to water. We are not aware that its analysis has been attempted.

The medical properties of this species of *Anthemis* are essentially the same as those of chamomile, for which it may be employed as a substitute; but its disagreeable odour is an obstacle to its general use. On the continent of Europe it has been given in nervous diseases, especially hysteria, under the impression, probably derived from its peculiar smell, that it possesses antispasmodic powers. It has also been thought to be emmenagogue. In this country it is scarcely employed, except as a domestic remedy. The whole plant is active; but the flowers, being less disagreeable than the leaves, are preferred for internal use. The remedy is best administered in the state of infusion. W.

CREASOTUM. U.S., Ed.

Creasote.

“A peculiar substance obtained from tar.” *U. S.*

Off. Syn. CREASOTON. Oxy-hydro-carburetum, *ex oleo pyroxylico paratum.* *Lond.*

This is a substance, of the nature of the volatile oils, discovered in 1830 by Dr. Reichenbach, of Moravia, in the products of the distillation of wood.

In the products of the distillation of organic substances generally, whether vegetable or animal, Reichenbach also discovered five other principles, called paraffine, eupione, picamar, capnomor, and pittacal, which, as being associated with creasote, will be noticed here. *Paraffine* is a white, crystalline, soft-solid, devoid of taste and smell, and characterized by its feeble affinity for other bodies, as is indicated by its name, from *parum affinis*. *Eupione* is an inodorous, insipid, limpid, and colourless liquid, of the sp. gr. 0.740, obtained most abundantly from animal tar, and Dippel's animal oil. Both these substances are composed exclusively of hydrogen and carbon. *Picamar* is an oily colourless liquid, heavier than water, of a peculiar odour and very bitter taste. It is present in the heaviest portion of the rectified oil of tar, and constitutes the bitter principle of that substance. *Capnomor*, so called from its being one of the ingredients of smoke, is a colourless liquid, lighter than water, having a pleasant odour and a pungent taste, and occurring in the heavy oil of tar. It has the property of dissolving caoutchouc, and is an ingredient in coal naphtha, which derives from its presence the

property of dissolving the same substance. *Pittacal*, also obtained from the heavy oil of tar, is a solid of a beautiful blue colour, and differing from the other substances above noticed, in containing nitrogen as one of its elements. These five substances have no uses.

Preparation. Creasote is obtained either from tar or from crude pyroligneous acid. When tar is used, it is distilled until it has attained the consistence of pitch. The distilled liquid divides itself into three layers, an aqueous between two oily layers. The inferior oily layer, which alone contains the creasote, is separated, and saturated with carbonate of potassa to remove acetic acid. The liquid is allowed to rest, and the new oil which separates is decanted from it. This oil is distilled, and yields products lighter than water, and a liquid heavier. The latter alone is preserved, and, having been agitated repeatedly with weak phosphoric acid to neutralize ammonia, is allowed to remain at rest for some time. It is next washed as long as acidity is removed, and then distilled with a fresh portion of weak phosphoric acid, care being taken to cohobate from time to time. The oily liquid thus rectified is colourless, and contains much creasote, but also a portion of eupione. To separate the latter, the liquid is mixed with a solution of caustic potassa of the density of 1.12, which dissolves the creasote, but not the eupione. The eupione, which swims above from its levity, being separated, the alkaline solution of the creasote is exposed to the air, until it becomes brown in consequence of the decomposition of a foreign matter, and is then saturated with sulphuric acid. This sets free the creasote, which is decanted and again distilled. The treatment by solution of potassa, sulphuric acid, &c., is to be repeated until the creasote no longer becomes brown by exposure to the air, but only slightly reddish. It is then dissolved in a stronger solution of potassa and distilled again, and finally re-distilled for the last time, rejecting the first portions which come over on account of containing much water, collecting the next portions, and avoiding to push the distillation too far. The product collected in this distillation is pure creasote.

When creasote is extracted from pyroligneous acid, the first step is to dissolve sulphate of soda in it to saturation. The oil which separates and swims above is decanted, and, having been allowed to remain at rest for a few days, is saturated by carbonate of potassa with the assistance of heat, and distilled with water. The oleaginous liquid obtained is of a pale yellow colour, and is to be treated with phosphoric acid, &c. &c., as above detailed with respect to the treatment of the corresponding oil obtained from tar.

According to M. Koene, the tar of the pine furnishes but little pure creasote; while coal tar, by his mode of treatment, yields nearly five drachms to the pint. We have not space for the insertion of his process, but the details may be consulted in the *Journal de Pharmacie*, 22^e Année, p. 89. M. Cozzi has also given a process which is stated to be economical. (*Amer. Journ. of Pharm.* x. 339, from the *Journ. de Chim. Med.*)

Properties. Creasote, when pure, is a colourless oleaginous liquid, of the consistence of oil of almonds, slightly greasy to the touch, volatilizable by heat, and having a caustic and burning taste, and a penetrating, disagreeable odour like that of smoked meat. As met with in the shops, it has frequently a brownish tinge. It burns with a sooty flame. Applied to the skin in a concentrated state, it corrugates and then destroys the cuticle. On paper it leaves a greasy stain, which disappears in a few hours, or in ten minutes when exposed to a heat of about 212°. Its sp. gr. is 1.037 (1.066 according to the Edinburgh Pharmacopœia). In favour of the latter number Dr. Christison adduces experimental results of his own, which are entirely satis-

factory. (*Christison's Dispensatory*, p. 374.) It boils at 397° , and retains its fluidity at -17° , and not probably at so low a temperature as -50° , as stated in the *London Pharmacopœia*.* It is a non-conductor of electricity, and refracts light powerfully. It is devoid of acid or alkaline reaction. Mixed with water, it forms two combinations—one a solution of 1 part of creasote in about 80 of water, the other, of 1 part of water in 10 of creasote. It unites in all proportions with alcohol, ether, and naphtha. It is capable of dissolving a large quantity of iodine and phosphorus, and a considerable portion of sulphur, especially when assisted by heat.

Creasote forms two combinations with potassa, one anhydrous, of an oleaginous consistence, the other, hydrated, and in the form of small, white pearly scales. It possesses similar habitudes with soda. It instantly dissolves ammonia, and retains it with great force. Nitric and sulphuric acids, in a concentrated state, decompose creasote; the former giving rise to abundant reddish vapours, the latter to a red colour, which becomes black on the addition of more of the acid. Acetic acid dissolves it in all proportions without decomposing it. Creasote dissolves a large number of metallic salts; and it reduces a few to the metallic state, as, for example, nitrate and acetate of silver. It acts powerfully in coagulating albumen, whether of the egg, or of the serum of the blood.

Of all the properties of creasote, the most remarkable is its power of preserving meat. It is this property which has suggested its name, derived from *κρέας*, *flesh*, and *σώζω* *I save*. Reichenbach states that fresh meat, dipped for a quarter of an hour in a solution of creasote, is preserved from putrefaction, and concludes that smoked meats owe their power to resist change to the presence of this substance.

Impurities and Adulterations. Creasote is apt to contain eupione, picamar, and capnomor, and is sometimes adulterated with rectified oil of tar, and the fixed and volatile oils. All these substances are detected by strong acetic acid, which dissolves the creasote, and leaves them behind, floating above the creasote solution. Fixed oils are also discovered by a stain on paper, not discharged by heat. Any trace of the matter which produces the brownish tinge, is detected by the liquid becoming discoloured by exposure to sunshine. Specific gravity is not a good criterion for the purity of creasote; because it is apt to be adulterated by liquids both heavier and lighter than itself, and hence may have the proper density without being pure. If it be very light, the presence of alcohol may be suspected. This adulteration may be separated by distillation, and will first come over, distinguishable by burning with a clear instead of a smoky flame.

Medical Properties, &c. Creasote is irritant, narcotic, styptic, antiseptic, and moderately escharotic. Internally it has been employed in a number of diseases; externally, for the most part as an application to eruptions, wounds, and ulcers, and as an injection and gargle. The principal diseases in which it has been given are diabetes mellitus, epilepsy, hysteria, neuralgia, chronic catarrh, hemoptysis, and pulmonary consumption. Over the latter disease it has no curative influence; but it is stated to facilitate expectoration and to give the sputa a more favourable

* The French authorities state that creasote remains fluid at 27° below zero, (Cent.) This is equivalent to 48.6° below freezing of Fahr. It is probable that the London College has inadvertently considered this number as indicating the number of degrees below zero of Fahr., instead of below freezing, and has taken the round number, 50° below zero, as a sufficiently near approximation. Mr. Phillips has not adopted the number of the *London Pharmacopœia*; but has committed the error of giving the temperature at 17° instead of 17° below zero. (See his *Trans. Lond. Pharm. Fourth Ed.* 392.)

character. In this disease, and in bronchorrhœa without inflammation, it has been recommended to be inhaled in a state of vapour, by means of the ordinary inhaling bottle. Dr. Elliotson, of London, considers it an important remedy in arresting nausea and vomiting, when not dependent on inflammation or structural disease of the stomach, as in hysteria and pregnancy. He also recommends it, as well as Mr. A. B. Maddock, of London, as a preventive of sea-sickness. The eruptions to the treatment of which it has been supposed to be best suited, are those of a scaly character. In burns its efficacy has been insisted on, especially in those attended with excessive suppuration and fungous granulations. In recent burns, where the cuticle is not broken, Dr. John Sutherland found it useful, applied in an undiluted state. In chilblains also it is stated to be a useful application. When applied to wounds, it acts as a styptic, stopping the capillary hemorrhage, but possesses no power to arrest the bleeding from large vessels. Hence creasote water has been applied locally to arrest uterine hemorrhage and the bleeding from leech-bites. The ulcers, in the treatment of which it has been found most useful, are those of an indolent and gangrenous character, in which its several properties of escharotic, stimulant, and antiseptic are usefully brought into play. It is also praised as an application to syphilitic, scrofulous, and cancerous ulcers. In all these cases, the remedy must be used of appropriate strength, and continued with judgment; and in case it should irritate, its use should be suspended, or alternated with that of emollient and soothing applications. In fistulous ulcers, it proves a useful resource, used by injection, by exciting the callous surfaces and disposing them to unite. Dr. Hildreth, of Zanesville, Ohio, found it efficacious, mixed with mercurial ointment, in the proportion of ten to thirty drops to the ounce, in scrofulous ophthalmia, and scrofulous ulceration of the cornea. A small portion of the ointment is introduced under the upper eyelid, morning and evening, and rubbed over the whole globe. The application should be strong enough to produce a smarting pain for about five minutes. The local must of course be combined with constitutional treatment. (*Amer. Journ. of Med. Sci. Oct. 1842, p. 362.*) Dr. R. Dick, of Glasgow, recommends creasote as an internal remedy in chronic gonorrhœa, and gleet. In cases of putrid sorethroat, in which the use of a stimulant and antiseptic is required, a gargle of creasote acts beneficially; and in chronic suppuration of the external meatus of the ear, the same properties make it valuable as an injection. In deafness arising from deficient cerumen, Mr. Curtis has found it useful. The meatus is first well cleansed, and afterwards brushed over, night and morning, with a mixture of a drachm of creasote to four drachms of oil of almonds, by means of a camel's hair brush. Dr. Partridge, of this city, has found the same treatment advantageous in several cases of deafness. The meatus may be cleansed by dropping into the ear at night a few drops of olive oil, and syringing it out the next morning with a weak and warm solution of castile soap, to which a sixth of cologne water has been added. This may be repeated five or six days, until the ear is thoroughly cleansed. (*Med. Exam. iii. 347.*) In toothache, dependent on destruction of the tooth and exposure of the nerve, creasote often acts promptly and radically in the removal of the pain. One or two drops of the pure substance must be carefully introduced into the hollow of the tooth, on a little cotton, avoiding contact with the tongue or cheek. To render the remedy effectual, the hollow of the tooth must be well cleaned out before it is applied.

Creasote is employed in the pure state, in mixture or solution, and in the form of ointment. (See *Mistura Creasoti*, and *Unguentum Creasoti*.) In

the pure state, it may be brushed over indolent or ill conditioned ulcers, or applied by means of lint, to arouse their sensibility, or to create a new action. Internally it is given in the dose of one or two drops, or more, repeated several times a day, diluted with weak mucilage, in the proportion of half a fluidounce to the drop. When used as a lotion for eruptions, ulcers, or burns, or as a gargle or injection, it is employed in solution, containing two, four, or six drops to the fluidounce of distilled water; the strength being determined by the circumstances of each particular case. In some cases the solution of creasote is used externally, mixed with poultices.

Three or four drops of creasote, added to a pint of ink, is said effectually to prevent its becoming mouldy. Dr. Christison finds from experiment, that creasote water is as good a preservative of some anatomical preparations as spirit, with the advantage of not hardening the parts. It is to creasote that the antiseptic properties of wood-smoke and of pyroligneous acid are probably due.

Creasote, in an overdose, acts as a poison. It produces giddiness, obscurity of vision, depressed action of the heart, convulsions and coma. No antidote is known to its poisonous effects. The treatment consists in the administration of ammonia and other stimulants.

According to Etting, taking the mean of two experiments, creasote consists of 7.8 hydrogen, 76.2 carbon, and 16 oxygen, proportions which coincide most nearly with nine equiv. of hydrogen, fourteen of carbon, and two of oxygen. It appears, however, that the specimens analyzed were not entirely free from water.

CRETA. *U. S.*, *Lond.*, *Ed.*

Chalk.

“Native friable carbonate of lime.” *U. S.* “*Calcis Carbonas (friabilis).*” *Lond.* “Friable carbonate of lime.” *Ed.*

Off. Syn. CALCIS CARBONAS. CRETA ALBA. *Dub.*

Craie, Fr.; *Kreide, Germ.*; *Creta, Ital.*; *Greda, Span.*, *Port.*

Carbonate of lime, in the extended meaning of the term, is the most abundant of simple minerals, constituting, according to its state of aggregation and other peculiarities, the different varieties of calcareous spar, common and shell limestone, marble, marl, and chalk. It occurs also in the animal kingdom, forming the principal part of shells, and a small proportion of the bones of the higher orders of animals. Though insoluble in pure water, yet it is present in minute quantity in most natural waters, being dissolved in the carbonic acid which they contain. In the waters of limestone districts, it is a very usual impregnation, and causes purging in those not accustomed to their use. In all such cases, boiling the water, by expelling the carbonic acid, causes the carbonate to be deposited. Besides being officinal in the state of chalk, carbonate of lime is also ordered as it exists in marble and oyster-shell, and as obtained by precipitation. (See *Marmor*, *Testa*, and *Calcis Carbonas Præcipitatum.*) In the present article we shall restrict our observations to chalk.

Localities. Chalk occurs abundantly in the South of England and North of France. It has not been discovered in the United States. It occurs massive in beds, and very frequently contains nodules of flint, and fossil remains of land and marine animals.

Properties. Chalk is an insipid, inodorous, insoluble, opaque, soft-solid, generally white, but grayish-white when impure. It is rough to the touch, easily pulverized, and breaks with an earthy fracture. It soils the fingers, yields a trace when drawn across an unyielding surface, and when applied to the tongue adheres slightly. Its sp. gr. varies from 2·3 to 2·6. It is seldom a perfectly pure carbonate of lime, but contains, besides gritty siliceous particles, small portions of alumina and of oxide of iron. If pure it is entirely soluble in muriatic acid; but usually a little silica is left. If the muriatic solution is not precipitated by ammonia, it is free from alumina and oxide of iron. Like all carbonates, it effervesces with acids. Though insoluble in water, it dissolves in an excess of carbonic acid. It consists, like the other varieties of carbonate of lime, of one eq. of carbonic acid 22·12, and one of lime 28·5 = 50·62.

Pharmaceutical Uses. Chalk, on account of the gritty particles which it contains, is unfit for medical use, until it has undergone levigation, when it is called *prepared chalk*. (See *Creta Præparata*.) It is sometimes used, in the preparation of the alkaline bicarbonates, to furnish a stream of carbonic acid, when decomposed by dilute sulphuric acid; as in the London process for bicarbonate of potassa.

CROCUS. *U. S., Lond., Ed.*

Saffron.

“The stigmas of *Crocus sativus*.” *U. S., Ed.* “*Crocus sativus. Stigmata exsiccata.*” *Lond.*

Off. Syn. CROCUS SATIVUS. Stigmata. *Dub.*

Safran, *Fr.*, *Germ.*; Zafferano, *Ital.*; Azafran, *Span.*

CROCUS. *Sex. Syst.* Triandria Monogynia.—*Nat. Ord.* Iridaceæ.

Gen. Ch. Corolla six parted, equal. Stigmas convoluted. *Willd.*

Crocus sativus. Willd. *Sp. Plant.* i. 194; Woodv. *Med. Bot.* p. 763. t. 259. The common cultivated saffron is a perennial plant, with a rounded and depressed bulb or cormus, from which the flower rises a little above the ground upon a long, slender, white, and succulent tube. The flower is large, of a beautiful lilac or bluish-purple colour, and makes its appearance in September or October. The leaves are radical, linear, slightly revolute, dark green upon their upper surface with a white longitudinal furrow in the centre, paler underneath with a prominent flattened midrib, and enclosed at their base, together with the tube of the corolla, in a membranous sheath, from which they emerge soon after the appearance of the flower. The style hangs out on one side between two segments of the corolla, and terminates in three long convoluted stigmas, which are of a rich orange colour, highly odorous, rolled in at the edges, and notched at the summit. These stigmas are the official part of the plant.

The *C. sativus*, or *autumnal crocus*, is a native of Greece and Asia Minor, where it has been cultivated from the earliest ages of antiquity. It is also cultivated for medicinal use in Sicily, Spain, France, England, and other temperate countries of Europe. In Great Britain it has been found growing wild but is not thought to be indigenous. Large quantities of saffron are raised in Egypt, Persia, and Cashmere, whence it is sent to India. We cultivate the plant in this country chiefly, if not solely, as a garden flower.

In England the flowers appear in October, and the leaves continue green through the winter; but the plant does not ripen its seed, and is propagated by offsets from the bulb. These are planted in grounds prepared for the purpose, and are arranged either in rows, or in small patches at certain distances. The flowers are gathered soon after they show themselves, as the period of flowering is very short. (*Fée.*) The stigmas, or summits of the pistils, together with a portion of the style, are separated from the remainder of the flower, and carefully dried by artificial heat, or in the sun. During this process they are sometimes made to assume the form of a cake by pressure; but the finest saffron is that which has been dried loosely. The two forms are distinguished by the name of *hay-saffron* and *cake-saffron*. Five pounds of the fresh stigmas yield one pound of the dried. (*Duncan.*)

The English saffron, formerly most highly esteemed in this country, has disappeared from our market. What may be sold under that name is probably derived from other sources. Much of the drug is imported from Gibraltar, packed in canisters. Parcels of it are also brought from Trieste and other ports of the Mediterranean. The Spanish saffron is generally considered best. Genuine *cake-saffron* is at present seldom found in commerce.

Properties. Saffron has a peculiar, sweetish, aromatic odour, a warm, pungent bitter taste, and a rich deep orange colour, which it imparts to the saliva when chewed. The stigmas of which it consists are an inch or more in length, expanded and notched at the upper extremity, and narrowing towards the lower, where they terminate in a slender, capillary, yellowish portion, forming a part of the style. Analyzed by Vogel and Bouillon-Lagrange, it afforded 6.5 per cent. of a peculiar extractive matter, and 7.5 of an odorous volatile oil, together with wax, gum, albumen, saline matter, water, and vegetable fibre. The extractive matter was named by them *polychroïte*, from the changes of colour which it undergoes by the action of reagents. It is prepared by evaporating the watery infusion to the consistence of honey, digesting the residue in alcohol, filtering the tincture, and evaporating it to dryness. Thus obtained, it is in the form of a reddish-yellow mass, of an agreeable smell, slightly bitter, soluble in water and alcohol, and somewhat deliquescent. Its solution becomes grass-green by the action of nitric acid, blue and then violet by that of sulphuric acid, and loses its colour altogether on exposure to light, and by chlorine. According to M. Henry, Sen., it contains about 20 per cent. of volatile oil, which can be separated only by the agency of an alkali. When perfectly pure, it is of a brilliant red colour, soluble with difficulty in water which it renders yellow, and readily soluble in alcohol, and the fixed and volatile oils. M. Henry states that this colouring matter constitutes 42 per cent. of saffron, and the essential oil 10 per cent. It is to the latter that the medicine owes its active properties. It may be partially separated by distillation. It is yellow, of a hot, acrid, bitterish taste, and heavier than water, in which it is slightly soluble.

Adulterations. The high price of this medicine gives rise to frequent adulterations. Water is said to be very often added in order to increase its weight. Oil is also added for the same purpose, or to improve the appearance. Sometimes the flowers of other plants, particularly the *Carthamus tinctorius* or safflower, and the *Calendula officinalis* or officinal marygold, are fraudulently mixed with the genuine stigmas. They may be known by their shape, which is rendered obvious by throwing a portion of the suspected mass into hot water, which causes them to expand. (See *Carthamus.*) Other adulterations are the fibres of dried beef, the stamens of the

Crocus distinguishable by their yellow colour, the stigmas previously exhausted in the preparation of the infusion or tincture, and various mineral substances easily detected upon close examination.

Choice of Saffron. Saffron should not be very moist, nor very dry, nor easily pulverized, nor should it emit an offensive smell when thrown upon live coals. The freshest is the best, and that which is less than a year old should, if possible, be selected. It should possess in a high degree the characteristic properties of colour, taste, and smell. If it does not colour the fingers when rubbed between them, or has an oily feel, or a musty flavour, or a black, yellow, or whitish colour, it should be rejected. In the purchase of this medicine in cakes, those should be selected which are close, tough, and firm in tearing; and care should be taken to avoid *cakes of safflower*, which are probably more frequent in the market than those of genuine saffron.

As its activity depends, partly at least, on a volatile ingredient, it should be kept in well-stopped vessels. Some recommend that it should be enclosed in a bladder, and introduced into a tin case.

Medical Properties and Uses. Saffron was formerly considered highly stimulant and antispasmodic. It has been alleged that, in small doses, it moderately excites the different functions, exhilarates the spirits, relieves pain, and produces sleep; in large doses, gives rise to headache, intoxication, delirium, stupor, and other alarming symptoms; and Shröder asserts that, in the quantity of two or three drachms, it proves fatal. It was thought also to act powerfully on the uterine system, promoting menstruation. The ancients employed it extensively, both as a medicine and condiment, under the name of *crocus*. It was also highly esteemed by the Arabians, and enjoyed considerable reputation among the physicians of modern Europe till within a comparatively recent period. On the continent it is still much used as a stimulant and emmenagogue. But the experiments of Dr. Alexander have proved it to possess little activity as a medicine; and in Great Britain and the United States it is seldom prescribed. By old women and nurses saffron tea is frequently used in exanthematous diseases, to promote the eruption; a practice introduced by the humoral pathologists, but afterwards abandoned by the profession, and not greatly injurious only from the inactivity of the medicine. The chief use of saffron at present is to impart colour and flavour to officinal tinctures. From ten to thirty grains may be given for a dose.

CUBEBA. *U. S.*, *Dub.*

Cubebs.

“The berries of Piper Cubeba.” *U. S.* “Piper Cubeba, Fructus.” *Dub.*

Off. Syn. PIPER CUBEBA. Piper Cubeba. *Baccæ. Lond.*; CUBEBAÆ. Fruit of Piper Cubeba. *Ed.*

Cubebe, *Fr.*; Kubeben, *Germ.*; Cubebe, *Ital.*; Cubebas, *Span.*; Kebabeh, *Arab.*

PIPER. *Sex. Syst.* Diandria Trigynia.—*Nat. Ord.* Piperacæ.

Gen. Ch. Calyx none. Corolla none. Berry one-seeded. Willd.

Piper Cubeba. Willd. *Sp. Plant.* i. 159; Woodv. *Med. Bot.* 3d Ed. v. 95.

This is a climbing perennial plant, with a smooth, flexuous, jointed stem, and entire, petiolate, oblong or ovate oblong, acuminate leaves, rounded or obliquely cordate at the base, strongly nerved, coriaceous, and very smooth. The flowers are diœcious and in spikes, with peduncles about as long as the petiole. The fruit is a globose, pedicelled berry.

This species of *Piper* is a native of Java, Penang, and probably other parts of the East Indies. It grows wild in the woods, and does not appear to be cultivated. The dried unripe fruit is the officinal portion. Dr. Blume thinks it probable that the drug is derived chiefly from another species—the *P. caninum* inhabiting the same countries; but Dr. Lindley could discover no difference between the fruit of the *P. cubeba* and the cubebs sold in London.

Properties. Cubebs are round, about the size of a small pea, of a blackish or grayish-brown colour, and furnished with a short stock, which appears to be continuous with raised veins that run over the surface of the berry, and embrace it like a network. The shell is hard, almost ligneous, and contains within it a single loose seed, covered with a blackish coat, and internally white and oleaginous. The odour of the berry is agreeably aromatic; the taste warm, bitterish, and camphorous, leaving in the mouth a peculiar sensation of coolness, like that produced by the oil of peppermint. The powder is dark coloured and of an oily aspect. From 1000 parts of cubebs, M. Monheim obtained 30 parts of a ceruminous substance, 25 of a green volatile oil, 10 of a yellow volatile oil, 45 of *cubebin*, 15 of a balsamic resin, 10 of chloride of sodium, 60 of extractive, and 650 of lignin, with 155 parts lost. According to MM. Capitaine and Soubeiran, *cubebin* is best obtained by expressing cubebs from which the oil has been distilled, preparing with it an alcoholic extract, treating this with a solution of potassa, washing the residue with water, and purifying it by repeated crystallizations in alcohol. Thus prepared, it is white, inodorous, and insipid, not volatilizable by heat, almost insoluble in water, slightly soluble in cold alcohol, freely so in that liquid when hot, and soluble also in ether, acetic acid, and the fixed and volatile oils. It bears a close resemblance to piperin, but differs from it in composition. (*Journ. de Pharm.* xxv. 355.) The volatile oil is officinal. (See *Oleum Cubebæ*.) Cubebs gradually deteriorate by age; and in the state of powder become rapidly weaker, in consequence of the escape of their active volatile ingredient. They should always be kept whole, and pulverized at the time of dispensing them. The powder is said to be sometimes adulterated with that of pimento.

Medical Properties and Uses. Cubebs are gently stimulant, with a special direction to the urinary organs. In considerable quantities they usually excite the circulation, increase the heat of the body, and sometimes occasion headache and giddiness. At the same time they frequently produce an augmented flow of the urine, to which they impart a peculiar odour. Nausea and moderate purging are also occasional attendants upon their operation; and they are said to give rise to a sense of coolness in the rectum during the passage of the feces. We have no evidence that they were known to the ancients. They were probably first brought into Europe by the Arabians; and were formerly employed for similar purposes with the black pepper; but they were found much less powerful and fell into disuse. Some years since they were again brought into notice in England as a remedy in gonorrhœa, and have been found very efficient in this complaint by numerous practitioners, not only of Great Britain, but of the continent of Europe and

of the United States. This application of cubebs was derived from India, where they have long been used in gonorrhœa, gleet, and as a grateful stomachic and carminative in disorders of the digestive organs. They are said to have occasionally produced swelled testicle when given in the first mentioned complaint; and, though recommended in all its stages, will probably be found most safe and effectual in cases where the inflammatory action is confined to the mucous membrane of the urethra. If not speedily useful, they should be discontinued. They have been given also in leucorrhœa, cystirrhœa, abscess of the prostate gland, piles, and chronic bronchial inflammation. They are best administered in the form of powder, of which the dose in gonorrhœa is from one to three drachms, repeated three or four times a day. For other affections the dose is sometimes reduced to ten grains. The volatile oil may be substituted for the powder, in the dose of ten or twelve drops, suspended in water by the intervention of sugar.

In Loudon's Encyclopædia of plants, it is stated that the berries of the *Uvaria Zeylanica* of Ceylon are used as a specific for gonorrhœa, under the name of cubebs. They are, however, wholly different from the genuine drug, and may be distinguished by containing four seeds in each berry, while the latter has but one.

CUPRUM.

Copper.

Cuivre, *Fr.*; Kupfer, *Germ.*; Rame, *Ital.*; Cobre, *Span.*

This metal is not officinal in the metallic state, but furnishes several important preparations. It is very generally diffused in nature, and exists principally in four states; as native copper, as an oxide, as a sulphuret, and as a salt. Its principal native salts are the sulphate, carbonate, arseniate, and phosphate. In the United States it has been found in various localities. The principal copper mines in the world, are those of the Pyrenees in France, Cornwall in England, and Fahlun in Sweden.

Properties. Copper is a brilliant, sonorous metal, of a reddish colour, and very ductile, malleable, and tenacious. It has a slightly nauseous taste, and emits a disagreeable smell when rubbed. Its texture is granular, and its fracture hackly. Its sp. gr. is 8.89, and its fusing point, 1996 F. according to Daniell; being intermediate in fusibility between silver and gold. Its equivalent number is 31.6. Exposed to the air it undergoes a slight tarnish. Its combinations are numerous and important. With oxygen it forms two well characterized oxides, a red suboxide or dioxide, consisting of two eqs. of copper and one of oxygen; and a black protoxide formed of one eq. of metal and one of oxygen. The latter oxide, which alone is salifiable, forms with acids several salts, important in medicine and the arts. With metals copper forms numerous alloys, of which that with zinc, called brass, is the most useful.

Characteristics. Copper is recognised by its colour and the effect of tests on its nitric solution. This solution, with potassa, soda, and ammonia, yields a blue precipitate, soluble in excess of the latter alkali, with which it forms a deep blue liquid. Ferrocyanuret of potassium occasions a brown precipitate of ferrocyanuret of copper; and a bright plate of iron immersed in the solution, immediately becomes covered with a film of metallic

copper. The ferrocyanuret of potassium is an exceedingly delicate test for detecting minute portions of copper in solution. Another test, proposed by M. Verguin, is to precipitate the copper in the metallic state on platinum by electro-chemical action. For this purpose a drop of the liquid to be examined is placed on a slip of platinum foil, and a slip of bright iron is brought in contact with the platinum and the liquid. If copper be present, it will be instantly precipitated on the surface of the platinum. (*Journ. de Pharm.* xxvii. 367.)

Action on the Animal Economy. Copper, in its pure state, is perfectly inert, but in combination is highly deleterious. Nevertheless a certain small portion of the metal, so far as researches have extended, is always present in the healthy body. Its combinations, when taken in poisonous doses, produce a coppery taste in the mouth; nausea and vomiting; violent pain of the stomach and bowels; frequent black and bloody stools; small, irregular, sharp, and frequent pulse; faintings; burning thirst; difficulty of breathing; cold sweats; paucity of urine; violent headache; cramps, convulsions, and finally death. The best treatment in cases of poisoning by copper, is to administer white of eggs, diffused in water, in large and repeated doses. If this remedy be not at hand, the patient must in the mean time be gorged with warm water, or with milk, and the throat irritated by the finger or a feather, with a view to excite vomiting. Should vomiting not take place by these means, the stomach-pump may be employed. The efficacy of the new antidote, (bicarbonate of soda,) proposed by W. Benoist, requires confirmation; and his objections to the white of eggs are probably unfounded.

In medico-legal examinations, where cupreous poisoning is suspected, Orfila recommends that the viscera be boiled in distilled water for an hour, and that the matter obtained by evaporating the filtered decoction to dryness, be carbonized by nitric acid. The matter thus treated will contain the copper. By proceeding in this way, there is no risk of obtaining the copper naturally existing in the animal tissues. This method of proceeding is preferable to examining the contents of the stomach and intestines, from which copper may be absent, while yet it may have penetrated the different organs by absorption, especially the abdominal viscera.

Vessels of copper should be discontinued in all operations connected with pharmacy and domestic economy; for, although the metal uncombined is inert, yet the risk is great that the vessel may be acted on, in which event, whatever may be contained in it would be rendered deleterious.

Pharm. Prep. The following is a list of all the preparations containing copper, in the U. S. and British Pharmacopœias, arranged so as to exhibit the synonyms.

CUPRI SUBACETAS. U.S., Dub.

Subacetate of Copper.

“Impure subacetate of copper.” U.S.

Off. Syn. ÆRUGO, *Lond., Ed.*

Verdigris; Acetate de cuivre brut, *Vert-de-gris, Fr.*; Grünspan, *Germ.*; Verde rame, *Ital.*; Cardenillo, *Span.*

Preparation. Verdigris is prepared in large quantities in the South of France, more particularly in the neighbourhood of Montpellier. It is also manufactured in Great Britain and Sweden. In France the process is conducted in the following manner. Sheets of copper are stratified with the refuse of the grape which remains after the expression of the juice in making wine, and allowed to remain in this state for a month or six weeks. At the end of this time, the plates are found coated with a considerable quantity of verdigris. This is scraped off, and the plates are then replaced as at first, to be further acted on. The scrapings thus obtained form a paste, which is afterwards well beaten with wooden mallets, and packed in oblong leathern bags, about ten inches in length by eight in breadth, in which it is dried in the sun, until the loaf of verdigris, as it is called, attains the proper degree of hardness. The rationale of the process is easily understood. The grape-refuse contains a considerable quantity of juice, which, by contact with the air, undergoes the acetous fermentation. The copper becomes oxidized, and, by subsequent combination with the acetic acid generated during the fermentation, forms the subacetate of copper or verdigris. In England a purer verdigris is prepared by alternating copper plates with pieces of woollen cloth steeped in pyroligneous acid.

Verdigris comes to this country exclusively from France, being imported principally from Bordeaux and Marseilles. The leathern packages in which it is put up, called sacks of verdigris, weigh generally from twenty-five to thirty pounds, and arrive in casks, each containing from thirty to forty sacks.

Properties. Verdigris is in masses of a pale green colour, and composed of a multitude of minute silky crystals. Sometimes, however, it occurs of a bright blue colour. Its taste is coppery. It is insoluble in alcohol, and, by the action of water, a portion of it is resolved into the neutral acetate which dissolves, and a triacetate which remains behind in the form of a dark green powder, gradually becoming black. It is hence evident that, when verdigris is prepared by levigation with water, it is altered in its nature. The neutral acetate is the crystallized acetate of copper of the Dublin College (see *Cupri Acetas. Crystalli*); while the triacetate may be viewed as identical with the prepared verdigris (see *Cupri Subacetat. Præparatum*). When acted on by sulphuric acid, it is decomposed, vapours of acetic acid being evolved, easily recognised by their vinegar odour. It is soluble almost entirely in ammonia, and dissolves in muriatic acid, with the exception of impurities, which should not exceed five per cent. When of good quality, it has a lively green colour, is free from black or white spots, and is dry and difficult to break. The green rust, called in popular language verdigris, which copper vessels are apt to contract when not kept clean, is a carbonate of copper, and must not be confounded with real verdigris.

Composition. Verdigris, apart from its impurities, is a variable mixture of the subacetates of copper; the subsesquiacetate predominating in the green variety, the diacetate in the blue. The London College defines it to be an impure diacetate of copper; the Edinburgh, the commercial diacetate.

When acted on by water, the portion consisting of diacetate is converted into soluble neutral acetate, and insoluble triacetate, as above mentioned.

Medical Properties and Uses. Verdigris is used externally as a detergent and escharotic, and is occasionally applied to chronic eruptions, foul and indolent ulcers, and venereal warts. The special applications of it will be mentioned under its preparations. For its effects as a poison, and the mode of treatment, the reader is referred to the article *Cuprum*.

Off. Prep. Cupri Subacetas Præparatum, *Dub.*; Emplastrum Cantharidis Compositum, *Ed.*; Linimentum Æruginis, *Lond.*; Unguentum Cupri Subacetatis, *U. S.*, *Ed.* B.

CUPRI ACETAS. Crystalli. *Dub.*

Crystals of Acetate of Copper.

Distilled verdigris, Crystals of Venus, neutral acetate of copper; Cristaux de Venus, Verdet cristallisé, *Fr.*; Destillirter Grünspan, Kupferkrystallen, *Germ.*

Crystallized acetate of copper is prepared principally at Montpellier, in France. The verdigris which is made in private houses is collected and carried to the manufactory. It is there dissolved in vinegar by the assistance of heat, and the solution, after having been sufficiently concentrated, is transferred to suitable vessels, where it crystallizes on cooling. The crystallization is facilitated by inserting sticks in the liquid, split in four longitudinally, the several portions being kept apart by small wedges of wood. On these the crystals are deposited.

This salt has a deep blue colour and strong styptic taste, crystallizes in rhomboidal prisms, and effloresces slightly in the air. It dissolves in water, without residue, a character which serves to distinguish it from verdigris. It consists of one eq. of acetic acid, one of protoxide of copper, and one of water. Its popular name of distilled verdigris is incorrect; as no distillation is practised in its preparation.

Medical and Pharmaceutical Uses. It is not very obvious for what reason the Dublin College has included this among its official preparations. It is sometimes employed in pharmacy for the purpose of obtaining acetic acid, which may be disengaged from it by the action of sulphuric acid; and the larger proportional quantity of acetic acid which it contains makes it more eligible for this purpose than verdigris. It enters into no official preparation. B.

CUPRI SULPHAS. *U. S.*, *Lond.*, *Ed.*, *Dub.*

Sulphate of Copper.

Blue vitriol, Roman vitriol, Blue stone; Sulfate de cuivre, Vitriol bleu, Couperose bleu, *Fr.*; Schwefelsaures Kupfer, Kupfervitriol, Blauervitriol, Blauer Galitzenstein, *Germ.*; Rame solfato, Vitriolo di rame, Vitriolo di Cipro, *Ital.*; Sulfato de cobre, Vitriolo azul, *Span.*

Preparation, &c. Sulphate of copper occasionally exists in nature, in solution in the water which flows through copper mines. In this case the salt is obtained by merely evaporating the waters which naturally contain it. Another method for obtaining it, is to roast the native sulphuret in a reverberatory furnace, whereby it is made to pass, by absorbing oxygen, into the state of sulphate. The roasted mass is lixiviated, and the solution obtained evaporated that crystals may form. The salt procured by either of these methods, contains a little sulphate of the sesquioxide of iron, from

which it may be freed by adding an excess of protoxide of copper, which has the effect of precipitating the iron. A third method consists in wetting, and then sprinkling with sulphur, sheets of copper, which are next heated to redness for some time, and afterwards plunged into water while yet hot. The same operation is repeated until the sheets are entirely corroded. At first a sulphuret is formed, which by the action of heat and air gradually passes into the state of sulphate. This is dissolved in the water, and is obtained in crystals by evaporation.

Sometimes sulphate of copper is obtained as a secondary product, in pursuing one of the methods for separating silver from gold. The silver is separated by boiling the alloy in sulphuric acid. The sulphate of silver formed is then decomposed by the immersion of copper plates, with the effect of forming sulphate of copper, and precipitating the silver.

Properties. Sulphate of copper has a rich deep-blue colour, and strong metallic styptic taste. It reddens vegetable blues, and crystallizes in large, transparent, rhomboidal prisms, which effloresce slightly in the air and become greenish, and are soluble in four parts of cold, and two of boiling water, but insoluble in alcohol. When heated, it first melts in its water of crystallization, and then dries and becomes white. If the heat be increased, it next undergoes the igneous fusion; and finally, at a high temperature, loses its acid, protoxide of copper being left. Potassa, soda, and ammonia throw down from it a bluish-white precipitate of hydrated protoxide of copper, which is immediately dissolved by an excess of the last mentioned alkali, forming a rich deep-blue solution, called in early pharmacy, *aqua sapphirina*. It is also decomposed by the alkaline carbonates, and by a number of important salts, such as borax, acetate and subacetate of lead, acetate of iron, nitrate of silver, corrosive chloride of mercury, tartrate of potassa, and chloride of calcium; and it is precipitated by all astringent vegetable infusions. Of course it must not be associated in prescription with any of these substances. If it become very green on the surface by the action of the air, it shows the presence of sesquioxide of iron. This oxide may also be detected by ammonia, which will throw it down along with the oxide of copper, without taking it up when added in excess. The salt consists of one eq. of sulphuric acid, one of protoxide of copper, and five of water.

Medical Properties. Sulphate of copper, in small doses, is deemed astringent and tonic; in large ones, a prompt emetic. With a view to its tonic effect it has been given in intermittent fever, as well as in epilepsy and some other spasmodic diseases; and as an emetic, for discharging poisons from the stomach, especially opium. In croup it has been employed as an emetic with encouraging success. It has of late been highly recommended in chronic diarrhœa. Externally it is employed in solution as a stimulant to ill-conditioned ulcers, as an escharotic for destroying warts, fungous granulations, and callous edges, and as a styptic to bleeding surfaces. It is found, in not a few instances, to promote the cicatrization of ulcers; and it is not unfrequently employed, with that view, as a wash for chancres. In weak solution, either alone or associated with other substances, it forms a useful collyrium in the chronic stages of some forms of ophthalmia. Eight grains of it, mixed with an equal weight of Armenian bole and two grains of camphor, and added to half a pint of boiling water, forms, after becoming limpid by rest, a collyrium strongly recommended by Mr. Ware, as a substitute for *Bates's Aqua Camphorata*, in the purulent ophthalmia of infants. The dose, as an astringent or tonic, is a quarter or half a grain, gradually increased; as an emetic, from two to five grains. As a stimulant wash, the

solution may be made of the strength of two, four, or eight grains to the fluid-ounce of water. Orfila cautions against giving large doses of this salt as an emetic in cases of poisoning; as it is apt, from its poisonous effects, to increase the mischief, where it happens not to be expelled by vomiting, by reason of the insensibility of the stomach. Upon the whole, such is the activity of the sulphate of copper, that it should be exhibited with the greatest caution. For its effects as a poison, see *Cuprum*.

Safran des Indes, *Fr.*; Kurkuma, Gilbwurz, *Germ.*; Curcuma, *Ital., Span.*; Zirsood, *Arab.*; Huldie, *Hindoo*.

CURCUMA. *Sex. Syst.* Monandria Monogynia.—*Nat. Ord.* Zingiberacæ.

Gen. Ch. Both limbs of the corolla three-partite. *Anther* with two spurs at the base. *Seeds* with an arillus. *Loudon's Encyc.*

Curcuma longa. Willd. *Sp. Plant.* i. 14; Woodv. *Med. Bot.* p. 737. t. 252. The root of this plant is perennial, tuberous, palmate, and internally of a deep yellow or orange colour. The leaves are radical, large, lanceolate, obliquely nerved, sheathing at their base, and closely embrace each other. The scape or flower-stem, which rises from the midst of the leaves, is short, thick, smooth, and constitutes a spike of numerous imbricated bracteal scales, between which the flowers successively make their appearance. The plant is a native of the East Indies and Cochinchina, and is cultivated in various parts of Southern Asia, particularly in China, Bengal, and Java, whence the root is exported. The best is said to come from China.

The dried root is in cylindrical or oblong pieces, about as thick but not as long as the finger, tuberculated, somewhat contorted, externally yellowish-brown, internally deep orange-yellow, hard, compact, and breaking with a fracture like that of wax. Another variety, comparatively rare, is round or oval, about the size of a pigeon's egg, and marked externally with numerous annular wrinkles. It is distinguished by the name of *curcuma rotunda*, the former being called *curcuma longa*. The two varieties have a close resemblance in sensible properties, and are thought to be derived from the same plant, though formerly ascribed to different species of *Curcuma*. The odour of turmeric is peculiar; the taste warm, bitterish, and feebly aromatic. It tinges the saliva yellow, and affords an orange-yellow powder. Analyzed by Pelletier and Vogel, it was found to contain lignin, starch, a peculiar yellow colouring matter called *curcumin*, a brown colouring matter, gum, an odorous and very acrid volatile oil, and a small quantity of chloride of calcium. Curcumin is obtained, mixed with a little volatile oil, by digesting the alcoholic extract of turmeric in ether, and evaporating the ethereal tincture. It may be procured entirely pure by separating it from its combination with oxide of lead. It is brown in mass, but yellow in the state of powder, without odour or taste, scarcely soluble in water, but very soluble in alcohol, ether, and the oils. The alkalies rapidly change its colour to a reddish-brown; and paper tinged with tincture of turmeric is employed as a test of the presence of these bodies. Berzelius, however, states that its colour is changed to red or brownish-red by the concentrated mineral acids, by pure

boracic acid, especially when dissolved in alcohol, and by numerous metallic salts; so that its indications cannot be certainly relied on. Its alcoholic solution produces coloured precipitates with acetate of lead, nitrate of silver, and other salts. Turmeric is used for dyeing yellow; but the colour is not permanent.

Medical Properties, &c. This root is a stimulant aromatic, bearing some resemblance to ginger in its operation, and is much used in India as a condiment. It is a constant ingredient in the curries so generally employed in the East. In former times it had some reputation in Europe as a remedy in jaundice and other visceral diseases; but at present it is employed only to impart colour to ointments, and other pharmaceutic preparations.

Turmeric paper, used as a test, is prepared by tinging white unsized paper with a tincture or decoction of turmeric. The tincture may be made with one part of turmeric to six parts of proof spirit; the decoction, with one part of the root to ten or twelve parts of water. The access of acid or alkaline vapours should be carefully avoided. W.

CYDONIA. Lond.

Quince Seeds.

Cydonia vulgaris. Semina." Lond.

Semences de coings, *Fr.*; Quittenkerne, *Germ.*; Semi di cotogno, *Ital.*; Simiente de membrillo, *Span.*

The quince tree has been separated from the genus *Pyrus* and erected into a new one with the title *Cydonia*, which is now generally admitted by botanists. It differs from the *Pyrus* in the circumstance that the cells of its fruit contain many seeds, instead of two only as in the latter.

CYDONIA. *Sex. Syst.* Icosandria Pentagynia.—*Nat. Ord.* Pomeæ.

Gen. Ch. *Calyx* five-parted, with leafy divisions. *Apple* closed, many-seeded. *Testa* mucilaginous. *Loudon's Encyc.*

Cydonia vulgaris. *Pers. Enchir.* ii. 40.—*Pyrus Cydonia.* Willd. *Sp. Plant.* ii. 1020; Woodv. *Med. Bot.* p. 505. t. 182. The common quince tree is characterized as a species by its downy deciduous leaves. It does not require particular description. It is supposed to have been originally obtained from Crete, but grows wild in Austria, on the banks of the Danube. It is abundantly cultivated in this country. The fruit is about the size of a pear, yellow, downy, of a pleasant odour, and a rough, astringent, acidulous taste; and in each of its five cells contains from eight to fourteen seeds. Though not eaten in its raw state, it forms a very pleasant confection; and a syrup prepared from it may be used as a grateful addition to drinks in sickness, especially in looseness of the bowels, which it is supposed to restrain by its astringency. The seeds are the officinal portion.

They are ovate, angled, of a reddish-brown colour externally, white within, inodorous, and nearly insipid, being slightly bitter when long chewed. Their coriaceous envelope abounds in mucilage, which is extracted by boiling water. Two drachms of the seeds are sufficient to render a pint of water thick and ropy. It has been proposed by a German pharmacist to evaporate the decoction to dryness, and powder the residue. Three grains of this powder form a sufficiently consistent mucilage with an ounce of water. Dr. Pereira considers the mucilage of quince seeds as a peculiar substance, and proposes to call it *cydonin*. It differs from arabin in not yielding a precipitate with silicate of potassa, and from bassorin and cerasin, in being soluble in water both hot and cold.

Medical Properties, &c. The mucilage of quince seeds may be used for all the purposes to which other mucilaginous liquids are applied. It is preferred by some practitioners as a local application in conjunctival ophthalmia, but in this country is less used for this purpose than the infusion of sassafras pith.

CUMINUM. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Apiaceæ or Umbelliferæ.

Gen. Ch. Fruit ovate, striated. *Partial umbels* four. *Involucres* four-cleft.

Cuminum Cyminum. Willd. *Sp. Plant.* i. 1440; Woodv. *Med. Bot.* p. 142. t. 56. This is an annual plant, about six or eight inches high, having a round, slender, branching stem, with numerous narrow, linear, pointed, smooth, grass-like leaves, of a deep green colour. The flowers are white or purple, and disposed in numerous terminal umbels, which have very few rays, and are attended with general and partial involucres, consisting of three or four linear leaflets. The fruit consists of two oblong plano-convex half-fruits, commonly called seeds, united by their flat sides. The plant is a native of Egypt, but is cultivated for its fruit in Sicily, Malta, and other parts of Europe.

The cumin seeds of the shops are elliptical, flat on one side, convex, furrowed, and rough on the other, about one-sixth of an inch in length, and of a light brown colour. Each has seven longitudinal ridges. Two seeds are sometimes united together as upon the plant. Their odour is peculiar, strong, and heavy; their taste warm, bitterish, aromatic, and disagreeable. They contain much essential oil, which is lighter than water, of a yellowish colour, and has the sensible properties of the seeds.

Medical Properties and Uses. In medical properties they resemble the other aromatic fruits of umbelliferous plants, but are more stimulating. They are seldom used in the United States, and appear to have been retained by the London College merely as an ingredient in a stimulant and discutient plaster, which, however, has been discarded in the last edition of their Pharmacopœia. Their dose is from fifteen grains to half a drachm

Delphinium Consolida. Willd. *Sp. Plant.* ii. 1226; Loudon's *Encyc. of*

Plants, p. 473. 7832. The larkspur is a showy annual plant, with an erect, branched, slightly pubescent stem. Its leaves are divided into linear segments, widely separated, and forked at the summit. The flowers are usually of a beautiful azure blue colour, and disposed in loose terminal racemes, with peduncles longer than the bractes. The nectary is one-leaved, with an ascending horn nearly equalling the corolla. The seeds are contained in smooth, solitary capsules.

This species of larkspur has been introduced from Europe into this country, where it has become naturalized, growing in the woods and fields, and flowering in June and July.

Various parts of the larkspur have been employed in medicine; and the plant is said to have properties closely analogous to those of the *Delphinium Staphisagria*. (See *Staphisagriæ Semina*.) The flowers are bitter and acrid, and having formerly been supposed to possess the power of healing wounds, gave the name of *consolida* to the species. They were considered diuretic, emmenagogue, and vermifuge; but are not now used. The seeds are very acrid, are esteemed diuretic, and in large doses produce vomiting and purging. They were analyzed by Mr. Thomas C. Hopkins of Philadelphia, and found to contain *delphinia*, volatile oil, fixed oil, gum, resin, chlorophylle, gallic acid, and salts of potassa, lime, and iron. (*Am. Journ. of Pharm.* xi. 8.) A tincture prepared by macerating an ounce of the seeds in a pint of diluted alcohol, has been found useful in spasmodic asthma and dropsy. The dose is ten drops, to be gradually increased till some effects upon the system are evinced. The remedy has been employed both in America and England; and the seeds of an indigenous species, the *D. exaltatum*, have been applied to a similar purpose. The root probably possesses the same properties with other parts of the plant; but, though designated in the Pharmacopœia, is little if at all used. W.

DIANTHUS CARYOPHYLLUS. Flores. *Dub.*

Flowers of the Clove Pink.

DIANTHUS. *Sex. Syst.* Decandria Digynia.—*Nat. Ord.* Caryophyllaceæ.

Gen. Ch. Calyx cylindrical, one-leaved, with four scales at the base.

Petals five, with claws. Capsule cylindrical, one-celled. *Willd.*

Dianthus Caryophyllus. Willd. *Sp. Plant.* ii. 674; Woodv. *Med. Bot.* p. 579. t. 205. The clove pink or carnation is too well known to require minute description. It is a perennial, herbaceous plant, characterized as a species by its branching stem, its solitary flowers, the short ovate scales of its calyx, its very broad beardless petals, and its linear, subulate, channeled, glaucous leaves. Indigenous in Italy, it is every where cultivated in gardens for the beauty of its flowers, of which numerous varieties have been produced by horticulturists. Those are selected for medicinal use which have the deepest red colour, and the most aromatic odour. The petals should not be collected till the flower is fully blown, and should be employed in the recent state.

They have a fragrant odour said to resemble that of the clove. Their taste is sweetish, slightly bitter, and somewhat astringent. Both water and alcohol extract their sensible properties, and they yield a fragrant essential oil by distillation.

In Europe they are employed to impart colour and flavour to a *syrup* which serves as a vehicle for other less pleasant medicines. According to the directions of the former Ed. Pharmacopœia, this was prepared by

macerating one part of the flowers, without their claws, with four parts of boiling water for twelve hours, then filtering, and adding seven parts of sugar. W.

DIGITALIS. U.S., Ed.

Foxglove.

“The leaves of *Digitalis purpurea*.” *U. S., Ed.*

Off. Syn. DIGITALIS FOLIA. DIGITALIS SEMINA. *Digitalis purpurea. Folia. Semina. Lond. DIGITALIS PURPUREA. Folia. Dub. Digitale pourprée, Doightier, Fr.; Purpurrother Fingerhut, Germ.; Digitale purpurea, Ital.; Dedalera, Span.*

DIGITALIS. *Sex. Syst.* Didynamia Angiospermia.—*Nat. Ord.* Scrophulariaceæ.

Gen. Ch. Calyx five-parted. Corolla bell-shaped, five-cleft, ventricose. Capsule ovate, two-celled. *Willd.*

Digitalis purpurea. Willd. *Sp. Plant.* iii. 283; Woodv. *Med. Bot.* p. 218. t. 78. Foxglove is a beautiful plant, with a biennial or perennial, fibrous root, which in the first year sends forth large tufted leaves, and in the following summer, a single, erect, downy, and leafy stem, rising from two to five feet in height, and terminating in an elegant spike of purple flowers. The lower leaves are ovate, pointed, about eight inches in length and three in breadth, and stand upon short, winged footstalks; the upper are alternate, sparse, and lanceolate; both are obtusely serrated at their edges, and have wrinkled velvety surfaces, of which the upper is of a fine deep-green colour, the under paler and more downy. The flowers are numerous, and attached to the upper part of the stem by short peduncles, in such a manner as generally to hang down upon one side. At the base of each peduncle is a floral leaf, which is sessile, ovate, and pointed. The calyx is divided into five segments, of which the uppermost is narrower than the others. The corolla is monopetalous, bell-form, swelling on the lower side, irregularly divided at the margin into short obtuse lobes, and in shape and size bearing some resemblance to the end of the finger of a glove, a circumstance which has suggested most of the names by which the plant is designated in different languages. Its mouth is guarded by long soft hairs. Externally, it is in general of a bright purple colour; internally, is sprinkled with black spots upon a white ground. There is a variety of the plant in which the flowers are white. The filaments are white, curved, and surmounted by large yellow anthers. The style, which is simple, supports a bifid stigma. The seeds are very small, numerous, of a grayish-brown colour, and contained in a pyramidal, two-celled capsule.

The foxglove grows wild in most of the temperate countries of Europe, where it flowers in the middle of summer. In this country it is cultivated both as an ornamental garden plant, and for medicinal purposes. The leaves are the part usually employed, although the London College recognises the seeds also as official. Much care is requisite, in selecting, preparing, and preserving foxglove in order to insure its activity. The leaves should be gathered in the second year, immediately before or during the period of inflorescence, and those only should be chosen which are full grown and perfectly fresh. (*Geiger.*) It is said that those plants are preferable which grow spontaneously in elevated places, exposed to the sun. (*Duncan.*) As the leaf-stalk and mid-rib are comparatively inactive, they may be rejected. Withering recommends that the leaves should be dried either in the sunshine,

or by a gentle heat before the fire; and care should be taken to keep them separate during the drying process. Pereira states that a more common, and, in his opinion, a preferable mode, is to dry them in a basket, in a dark place, in a drying stove. It is probably owing, in part, to the want of proper attention in preparing digitalis for the market, that it is so often to be found inefficient. Much of the medicine kept in our shops is obtained from the settlement of the Shakers in New-York, and is in the state of oblong compact masses, into which the leaves are probably compressed before they are thoroughly dried. In some of these cakes the digitalis is of good quality; but we have seen others in which it was quite the reverse, and some which were mouldy in the interior; and upon the whole cannot but consider this mode of preparing the drug as objectionable. The dried leaves should be kept in tin canisters, well closed so as to exclude light and moisture, or they may be pulverized, and the powder preserved in well-stopped and opaque phials. As foxglove deteriorates by time, it should be frequently renewed, as often, if possible, as once a year. Its quality must be judged of by the degree in which it possesses the characteristic properties of colour, smell, and especially of taste.

Properties. Foxglove is without smell in the recent state, but acquires a faint narcotic odour when dried. Its taste is bitter and nauseous. The colour of the dried leaf is a dull pale green, modified by the whitish down upon the under surface; that of the powder is a fine deep green. Digitalis yields its virtues both to water and alcohol. The dried leaves, analyzed by Rein and Haase, were found to contain in 100 parts, 5.5 of a green resin, soft, viscid, soluble in alcohol, ether, and the volatile oils, and possessing the properties of a mixture of resin and fixed oil; 15.0 of gum mixed with a salt of potassa; 2.0 of superoxalate of potassa; 52.0 of lignin; 5.5 of water, with 5.0 parts lost. According to Haase, the virtues of digitalis depend upon the soft resin. (*Berzelius, Trait. de Chim.*) MM. Brault and Poggiale state, as the result of their researches, that the leaves contain chlorophylle, resin, a fatty matter, starch, vegetable fibre, gum, tannin, a volatile oil, and salts of lime and of potassa. They are disposed to ascribe the virtues of the plant chiefly to the resin, which has a bitter, acrid, almost corrosive taste. The pretended *digitalin* of M. Le Royer has turned out to be nothing more than a mixture of chlorophylle, resin, fatty matter, and different salts of lime and of potassa. (*Journ. de Pharm.* xxi. 130.) The results of analysis, in relation to the active principle of the drug, are as yet quite unsatisfactory. Dr. Morries obtained a narcotic empyreumatic oil by its destructive distillation.

Medical Properties and Uses. Digitalis is narcotic, sedative, and diuretic. When administered in quantities sufficient to bring the system decidedly under its influence, it is apt to produce a sense of tightness or weight with dull pain in the head, vertigo, dimness or other disorder of vision, and more or less confusion in the mental operations. At the same time, it occasionally gives rise to irritation in the pharynx and œsophagus, which extends to the larynx and trachea, producing hoarseness; and, in more than one instance, ptyalism has been observed to result from its action. It sometimes also disturbs the bowels, and excites nausea, or even vomiting. Another effect, which, in a practical point of view, is highly important, is an augmented flow of urine. This has been ascribed by some to the increased absorption which digitalis is supposed to produce; and in support of this opinion it is stated, that its diuretic operation is observable only when dropsical effusion exists; but the fact seems to be, that it is capable of augmenting the quantity of urine in health, and it probably exerts a directly stimulating influence

over the secretory function of the kidneys. This influence is said sometimes to extend to the genital organs.* Besides the various effects above detailed, digitalis exerts a remarkably sedative operation upon the heart. This is exhibited in the reduction both of the force and frequency of the pulse, which sometimes sinks from the ordinary standard to 50, 40, or even 30 strokes in the minute. In some instances, however, it undergoes little change; in others only becomes irregular; and we are told that it is even occasionally increased in frequency. It was observed by Dr. Baidon, that the effects of digitalis upon the circulation were very much influenced by posture. Thus, in his own case, the pulse which had been reduced from 110 to 40 in the recumbent position, was increased to 72 when he sat, and to 100 when he stood. We do not discover anything remarkable in this circumstance. It is well known that the pulse is always more frequent in the erect than in the horizontal posture, and the difference is greater in a state of debility than in health. Digitalis diminishes the frequency of the pulsations of the heart by a directly debilitating power; and this very debility, when any exertion is made which calls for increased action in that organ, causes it to attempt, by an increase in the number of its contractions, to meet the demand which it is wholly unable to supply by an increase in their force.

The various effects above detailed may result from digitalis given in doses calculated to produce its remediate influence. In larger quantities its operation is more violent. Nausea and vomiting, stupor or delirium, cold sweats, extreme prostration of general strength, hiccough, convulsions, syncope, are among the alarming symptoms which indicate the poisonous character of the medicine. These effects are best counteracted by stimulants, such as brandy, the volatile alkali, and opium. When there is reason to believe that any of the poison remains, it is obviously proper, before employing other measures, to evacuate the stomach by the free use of warm liquids.

A peculiarity of digitalis is that, after having been given in moderate doses for several days, without any apparent effect, it sometimes acts suddenly with an accumulated influence, endangering even the life of the patient. It is, moreover, very permanent in its operation, which, having once commenced, is maintained like that of mercury, for a considerable period, without any fresh accession of the medicine. The practical inferences deducible from these properties of digitalis, are first, that after it has been administered for some time without effect, great caution should be observed not to increase the dose, nor to urge the medicine too vigorously; and secondly, that after its effects have begun to appear, it should be suspended for a time, or exhibited in moderate doses, lest a dangerous accumulation of its influence should be experienced. In numerous instances death has resulted from its incautious employment.

Digitalis has been long known to possess medicinal powers; but it was never generally used, nor regarded as a standard remedy, till after its application by Withering to the treatment of dropsy, about the year 1775. It is at present employed very extensively, both for its diuretic power, and for its sedative influence over the circulation. The former renders it highly useful in dropsical diseases, though like all other remedies it very frequently fails; the latter adapts it to the treatment of cases in which the action of the heart requires to be controlled. The idea was at one period entertained, that it might serve as a substitute for the lancet in febrile and inflammatory complaints; and it has been much employed for this purpose by the Italian phy-

* See an account of experiments by Professors Jærg and others, of Leipsic, in the N. Am. Med. and Surg. Journ. vol. xi. p. 235.

sicians, who practised in accordance with the *contra-stimulant* doctrine; but experience has proved that it is a very frail support in any case in which the symptoms of inflammation are such as to call for the loss of blood. As an adjuvant to the lancet, and in cases in which circumstances forbid the employment of this remedy, it is often very useful. Though it certainly has not the power, at one time ascribed to it by some practitioners, of curing phthisis, it acts beneficially as a palliative in that complaint by depressing the excited movements of the heart. In the same way it proves advantageous in aneurism, hypertrophy and dilatation of the heart, palpitations from rheumatic or gouty irritation, and in various forms of hemorrhage, after action has been sufficiently reduced by the lancet. It has also been prescribed in mania, epilepsy, pertussis, and spasmodic asthma; and highly respectable testimony can be adduced in favour of its occasional efficacy in these complaints; but any good which may be derived from it is ascribable rather to its influence over the brain and nerves, than to that which it exercises over the circulation. In delirium tremens it has been recently recommended as a specific, given in the form of infusion, in the full dose, repeated every two hours till symptoms of narcotism are induced; but the practice is somewhat hazardous unless the patient be carefully watched. (*Am. Journ. of Med. Sci.* xvii. 501.) The medicine, externally applied, is said to act speedily and powerfully as a diuretic, and to have been used advantageously in dropsy. For this purpose the fresh leaves bruised, or the tincture may be rubbed over the abdomen and on the inside of the thighs. (*Revue Médicale*, May, 1834.)

Digitalis is most effectually administered in substance. The dose of the powder is one grain, repeated twice or three times a day, and gradually increased till some effect is produced upon the head, stomach, pulse, or kidneys, when it should be omitted or reduced. The infusion and tincture are officinal preparations often resorted to. (See *Infusum Digitalis*, and *Tinctura Digitalis*.) The extract has also been employed; and Orfila found it, whether prepared with water or alcohol, more powerful than the powder; but the virtues of digitalis are too energetic to require concentration; and the preparation is not more certain than the powder. The decoction has also been used, but has nothing to recommend it. Enormous doses of this medicine have sometimes been given with asserted impunity; and when they occasion full vomiting, it is possible that they may sometimes prove harmless; but when the alarming consequences which sometimes result from comparatively moderate doses are considered, the practice must be condemned as exceedingly hazardous.

DIOSMA. *U. S., Lond.*

Buchu.

“The leaves of *Diosma crenata*.” *U. S.* “*Diosma crenata. Folia.*” *Lond.*
Off. Syn. BUCKU. Leaves of various species of *Barosma*. *Ed.*; DIOSMA CRENATA. *Folia.* BUCHU. *Dub.*

This medicine consists of the leaves of different plants growing at the Cape of Good Hope, formerly ranked in the genus *Diosma*, but transferred by botanists to the genus *Barosma*, so named from the strong odour of the leaves. (Βαγρο and οσμή.) The *B. crenata*, *B. crenulata*, and *B. serrati-*

folia are described by Lindley as medicinal species. The leaves of these and other *Barosmas*, and of some *Agathosmas*, are collected by the Hottentots, who value them on account of their odour, and, under the name of *bookoo* or *buchu*, rub them, in the state of powder, upon their greasy bodies.

BAROSMA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Rutaceæ.

Gen. Ch. *Calyx* five-cleft or five-parted. Disk lining the bottom of the calyx generally with a short scarcely prominent rim. *Petals* five, with short claws. *Filaments* ten; the five opposite the petals sterile, petaloid; the other five longer, subulate. *Style* as long as the petals. *Stigma* minute, five-lobed. *Fruit* composed of five cocci covered with glandular dots at the back. (*Condensed from Lindley.*) These plants are all small shrubs, with opposite leaves, and peduncled flowers.

Barosma crenata. Lindley, *Flor. Med.* p. 213.—*Diosma crenata.* De Cand. *Prodrom.* i. 714; Woodv. *Med. Bot.* 3d Ed. v. 52. This is a slender shrub, with smooth, somewhat angular branches, of a purplish colour. The leaves are opposite, ovate or obovate, acute, serrated and glandular at the edge, coriaceous, and full of small pellucid dots on the under surface. The flowers are white or of a reddish tint, and stand solitarily at the end of short, lateral, leafy shoots.

Properties. The *buchu* leaves of the shops are from three quarters of an inch to an inch long, from three to five lines broad, elliptical, lanceolate ovate or obovate, sometimes slightly pointed, sometimes blunt at the apex, very finely notched and glandular at the edges, smooth and of a green colour on the upper surface, dotted and paler beneath, and of a firm consistence. Their odour is strong, diffusive, and somewhat aromatic; their taste bitterish, and closely analogous to that of mint. These various properties are abundantly sufficient to distinguish them from senna, with which they might be confounded upon a careless inspection. They are sometimes mixed with portions of the stalks and fruit. Analyzed by Cadet de Gassicourt, they were found to contain in 1000 parts, 6·65 parts of a light, brownish-yellow, and highly odorous volatile oil, 211·7 of gum, 51·7 of extractive, 11 of chlorophylle, and 21·51 of resin. Water and alcohol extract their virtues, which probably depend on the volatile oil and extractive matter. The latter is precipitated by the infusion of galls.

Medical Properties and Uses. *Buchu* leaves are gently stimulant, with a peculiar tendency to the urinary organs, producing diuresis, and, like all other similar medicines, exciting diaphoresis when circumstances favour this mode of action. The Hottentots at the Cape of Good Hope have long used them in a variety of diseases. From these rude practitioners they were borrowed by the resident English and Dutch physicians, by whose recommendation they have been employed to some extent in Great Britain and on the continent of Europe, and have attracted attention on this side of the Atlantic. They are chiefly given in complaints of the urinary organs, such as gravel, chronic catarrh of the bladder, morbid irritation of the bladder and urethra, disease of the prostate, and retention or incontinence of urine from a loss of tone in the parts concerned in its evacuation. The remedy has also been recommended in dyspepsia, chronic rheumatism and cutaneous affections. From twenty to thirty grains of the powder may be given two or three times a day. The leaves are also used in infusion, in the proportion of an ounce to a pint of boiling water, of which the dose is one or two fluidounces. A tincture has been employed as a stimulant embrocation in local pains.

DIOSPYROS. U.S. Secondary.

Persimmon.

“The bark of *Diospyros Virginiana*.” U. S.

DIOSPYROS. *Sex. Syst.* Diœcia Octandria.—*Nat. Ord.* Ebenaceæ.

Gen. Ch. MALE. *Calyx* four to six-cleft. *Corolla* urceolate, four to six-cleft. *Stamens* eight to sixteen; filaments often producing two anthers. FEMALE. *Flower* as the male. *Stigmas* four or five. *Berry* eight to twelve-seeded. *Nuttall*.

Diospyros Virginiana. Willd. *Sp. Plant.* iv. 1107; Michaux, *N. Am. Sylv.* ii. 219. The persimmon is an indigenous tree, rising in the Southern States in favourable situations to the height of sixty feet, with a trunk eighteen or twenty inches in diameter; but seldom attaining more than half this size near its northern limits, and often not higher than fifteen or twenty feet. The stem is straight, and in the old tree covered with a furrowed blackish bark. The branches are spreading; the leaves ovate oblong, acuminate, entire, smooth, reticulately veined, alternate, and supported on pubescent footstalks. The buds are smooth. The male and female flowers are on different trees. They are lateral, axillary, solitary, nearly sessile, of a pale orange colour, and not conspicuous. The fruit is a globular berry, of a dark yellow colour externally when perfectly ripe, and containing numerous seeds embedded in a soft yellow pulp.

This tree is very common in the Middle and Southern States; but, according to Michaux, does not flourish beyond the forty-second degree of north latitude. The flowers appear in May or June; but the fruit is not ripe till the middle of autumn. While in the green state, the fruit is excessively astringent; but when perfectly mature, and after having been touched by the frost, it is sweet and palatable. We are told by Michaux, that in the Southern and Western States it is made into cakes with bran, and used for preparing beer with the addition of water, hops, and yeast. A spirituous liquor may be obtained by the distillation of the fermented infusion. The unripe fruit has been advantageously used by Dr. Mettauer, of Virginia, in diarrhœa, chronic dysentery, and uterine hemorrhage. He gave it in infusion, syrup, and vinous tincture, prepared in the proportion of about an ounce of the bruised fresh fruit, to two fluidounces of the vehicle, and administered in the dose of a fluidrachm or more for infants, and half a fluidounce or more for adults. (*Am. Journ. of Med. Sci. N. S.* iv. 297.) The bark is the only part of the tree directed by the Pharmacopœia. It is astringent and very bitter; and is said to have been used advantageously in intermittents, and in the form of a gargle in ulcerated sorethroat. W.

DRACONTIUM. U.S. Secondary.

Skunk Cabbage.

“The root of *Dracontium fœtidum*—*Ictodes fœtidus* (Bigelow)—*Symplocarpus fœtidus* (Barton, *Med. Bot.*)” U. S.

Botanists have had some difficulty in properly arranging this plant. It is attached by Willdenow to the genus *Dracontium*, by Michaux and Pursh is considered a *Pothos*, and by American botanists has been erected into a new genus, which Nuttall calls *Symplocarpus* after Salisbury, and for which Dr. Bigelow has proposed the name *Ictodes*, expressive of the odour of the plant.

The term *Symplocarpus*, though erroneous in its origin, was first proposed for the new genus, and, having been adopted by several botanists, should be retained.

SYMPLOCARPUS. *Sex. Syst.* Tetrandria Monogynia.—*Nat. Ord.* Araceæ.

Gen. Ch. *Spathe* hooded. *Spadix* covered with perfect flowers. *Calyx* with four segments. *Petals* none. *Style* pyramidal. *Seeds* immersed in the spadix. *Bigelow*.

Symplocarpus fœtidus. Barton, *Med. Bot.* i. 123.—*Ictodes fœtidus*. Bigelow, *Am. Med. Bot.* ii. 41. The *skunk cabbage* is a very curious plant, the only one of the genus to which it belongs. The root is perennial, large, abrupt, and furnished with numerous fleshy fibres, which penetrate to the depth of two feet or more. The spathe, which appears before the leaves, is ovate, acuminate, obliquely depressed at the apex, auriculated at the base, folded inwards at the edges, and of a brownish-purple colour, varied with spots of red, yellow, and green. Within the spathe, the flowers which resemble it in colour, are placed in great numbers upon a globose, peduncled spadix, for which they form a compact covering. After the spathe has decayed, the spadix continues to grow, and, when the fruit is mature, has attained a size exceeding by several fold its original dimensions. The different parts of the flower, with the exception of the anthers, augment in like proportion. At the base of each style is a roundish seed, immersed in the spadix, about the size of a pea, and speckled with purple and yellow. The leaves, which rise from the ground after the flowers, are numerous and crowded, oblong, cordate, acute, smooth, strongly veined, and attached to the root by long petioles, which are hollowed in front, and furnished with coloured sheathing stipules. At the beginning of May, when the leaves are fully developed, they are very large, being from one to two feet in length, and from nine inches to a foot in breadth.

This plant is indigenous, growing abundantly in meadows, swamps, and other wet places, throughout the whole northern and middle sections of the Union. Its flowers appear in March and April, and in the lower latitudes often so early as February. The fruit is usually quite ripe, and the leaves are decayed before the end of August. The plant is very conspicuous from its abundance, and from the magnitude of its leaves. All parts of it have a disagreeable fetid odour, thought to resemble that of the offensive animal after which it is named. This odour resides in an extremely volatile principle, which is rapidly dissipated by heat, and diminished by desiccation. The root is the part usually employed in medicine. It should be collected in autumn, or early in spring, and dried with care.

The dried root, as found in the shops, consists of two distinct portions; the body or caudex, either whole or in transverse slices, and the separated radicles. The former, when whole, is cylindrical, or in the shape of a truncated cone, two or three inches long by about an inch in thickness, externally dark brown and very rough from the insertion of the radicles, internally white and amylaceous. The latter are in pieces of various lengths, about as thick as a hen's quill, very much flattened and wrinkled, white within, and covered by a yellowish reddish-brown epidermis, of a considerably lighter shade than that of the body of the root. The fetid odour remains, to a greater or less extent, for a considerable period after the completion of the drying process. The taste, though less decided than in the fresh state, is still acrid, manifesting itself, after the root has been chewed for a short time, by a pricking and smarting sensation in the mouth and throat. The acrimony, however, is dissipated by heat, and is entirely lost in decoction. It is also diminished by time and exposure; and the root should not

be kept for use longer than a single season. According to Mr. Turner, (see *Inaug. Essay in Am. Journ. of Pharm.* viii. 2.) the radicles, even in the recent plant, have less acrimony than the caudex. The seeds are said by Mr. Turner to have an exceedingly acrid taste, and, though inodorous when whole, to give out strongly, when bruised, the peculiar odour of the plant.

Medical Properties and Uses. The properties of this root are those of a stimulant, antispasmodic, and narcotic. In large doses it occasions nausea and vomiting, with headache, vertigo, and dimness of vision. Dr. Bigelow has witnessed these effects from thirty grains of the recently dried root. The medicine was introduced into notice by the Rev. Dr. Cutler, who recommended it highly as an antispasmodic in asthma; and it has been subsequently employed with apparent advantage in chronic catarrh, chronic rheumatism, and hysteria. Cures are also said to have been effected by its use in dropsy.

It is best given in powder, of which the dose is from ten to twenty grains, to be repeated three or four times a day, and gradually increased till some evidence of its action is afforded. A strong infusion is sometimes employed, and the people in the country prepare a syrup from the fresh root; but the latter preparation is very unequal. The root itself, as kept in the shops, is of uncertain strength, in consequence of its deterioration by age. W.

Bittersweet.

“The stalks of *Solanum Dulcamara*.” U.S. “*Solanum Dulcamara. Caulis.*” Lond., Dub. “Twigs of *Solanum Dulcamara*.” Ed.

Douce-amère, Fr.; Bittersüss, Alpranken, Germ.; Dulcamara, Ital., Span.

SOLANUM. Sex. Syst. Pentandria Monogynia.—Nat. Ord. Solanaceæ.

Gen. Ch. Corolla wheel-shaped. Anthers somewhat coalescing, opening by two pores at the apex. Berry two-celled. Willd.

This genus includes numerous species, of which several have been used in medicine. Besides the *S. Dulcamara*, which is the only officinal species, two others merit a brief notice. 1. The *Solanum nigrum*, the common garden or black nightshade, is an annual plant from one to two feet high, with an unarmed herbaceous stem, ovate, angular-dentate leaves, and white or pale violet flowers, arranged in peduncled nodding umbel-like racemes, and followed by clusters of spherical black berries, about the size of peas. There are numerous varieties of this species, one of which is a native of the United States. The leaves are the part employed in medicine. They are said to produce diaphoresis, sometimes diuresis and moderate purging, and in large doses nausea and giddiness. As a medicine they have been used in cancerous, scrofulous, and scorbutic diseases, and other painful ulcerous affections, being given internally, and applied at the same time in the form of poultice, ointment, or decoction to the tumours or ulcers themselves. A grain of the dried leaves may be given every night and gradually increased to ten or twelve grains, or till some sensible effect is experienced. The medicine, however, is scarcely used at present. By some persons the poisonous properties usually ascribed to the common nightshade are doubted. M. Dunal, of Montpellier, states as the result of numerous experiments, that the berries are not poisonous to man or the inferior animals; and the leaves are said to be consumed in large quantities in the Isles of France and Bourbon as food, having been previously boiled in water. In the latter case, the

active principle of the plant must have been extracted by decoction. 2. The *Solanum tuberosum*, or *common potato*, is interesting on account of the nutritive properties of its tubers, so extensively employed as food. The leaves, stalks, and unripe berries are asserted to have narcotic properties, and an extract prepared from the leaves has been employed as a remedy in cough and spasmodic affections, in which it is said to act like opium. (*Geiger.*) From half a grain to two grains may be given as a dose. Dr. Latham of London found the extract to produce very favourable effects in various chronic complaints, such as protracted cough, chronic rheumatism, angina pectoris, cancer of the uterus, &c. The influence which it exercised upon the nervous system was strongly marked, and, in many instances, the dose could not be increased above a few grains without giving rise to threatening symptoms. It appeared to Dr. Latham to be very analogous in its operation to digitalis. His experiments were repeated in Philadelphia by Dr. Worsham with very different results. The extract was found, in the quantity of nearly one hundred grains, to produce no sensible effect on the system. (*Philad. Journ. of Med. and Phys. Sciences*, vi. 22.) We can reconcile these opposite statements only upon the supposition, that the properties of the plant vary with the season, or with the place and circumstances of culture. An excellent form of starch, called potato arrow-root, is prepared from potatoes for medical use; and an imitation of sago is also made from them in Germany. Dr. Julius Otto found *solania* in the germs of the potato. He was induced to make the investigation by observing, that cattle were destroyed by feeding on the residue of germinated potatoes, used for the manufacture of brandy. (See *Journ. of Phil. Col. of Pharm.* vi. 348.)

Solanum Dulcamara. Willd. *Sp. Plant.* i. 1028; Woodv. *Med. Bot.* p. 237. t. 84; Bigelow, *Am. Med. Bot.* i. 169. The *bittersweet* or *woody nightshade* is a climbing shrub, with a slender, roundish, branching, woody stem, which, in favourable situations, rises six or eight feet in height. The leaves are alternate, petiolate, ovate, pointed, veined, soft, smooth, and of a dull green colour. Many near the top of the stem are furnished with lateral projections at their base, giving them a hastate form. Most of them are quite entire, some cordate at the base. The flowers are disposed in elegant clusters, somewhat analogous to cymes, and standing opposite to the leaves. The calyx is very small, purplish, and divided into five blunt persistent segments. The corolla is wheel-shaped, with five pointed reflected segments which are of a violet-blue colour, with a darker purple vein running longitudinally through their centre, and two shining greenish spots at the base of each. The filaments are very short, and support large erect lemon-yellow anthers, which cohere in the form of a cone around the style. The berries are of an oval shape and a bright scarlet colour, and continue to hang in beautiful bunches after the leaves have fallen.

This plant is common to Europe and North America. It flourishes most luxuriantly in damp and sheltered places, as on the banks of rivulets, and among the thickets which border our natural meadows. It is also found in higher and more exposed situations, and is frequently cultivated in gardens. In the United States it extends from New England to Ohio, and is in bloom from June to August. The root and stalk are possessed of the medicinal properties of the plant, though the latter only is officinal. The berries, which were formerly esteemed poisonous, and thought to act with great severity on the stomach and bowels, are now said to be innocuous. Bittersweet should be gathered in autumn, after the fall of the leaf; and the extreme twigs should be selected. That grown in high and dry situations is said to be the best.

The dried twigs, as brought to the shops, are of various lengths, cylindrical, about as thick as a goose-quill, externally wrinkled and of a grayish-ash colour, consisting of a thin bark, an interior ligneous portion, and a central pith. They are inodorous, though the stalk in the recent state emits, when bruised, a peculiar, rather nauseous smell. Their taste, which is at first bitter, and afterwards sweetish, has given origin to the name of the plant. Boiling water extracts all their virtues. These are supposed to depend, at least in part, upon a peculiar alkaline principle called *solanin* or *solanina*, which was originally discovered by M. Desfosses, of Besançon, in the berries of the *Solanum nigrum*, and has subsequently been found in the stalks, leaves, and berries of the *S. Dulcamara* and *S. tuberosum*. It is supposed to exist in the bittersweet combined with malic acid. It is obtained by precipitating the decoction of bittersweet with ammonia or magnesia, washing the precipitate with cold water, and then treating it with boiling alcohol, which deposits the alkaline principle on cooling, and still further by evaporation. *Solanina* is in the form of a white opaque powder, or of delicate acicular crystals, somewhat like those of sulphate of quinia, though finer and shorter. It is inodorous, of a bitter taste, fusible at a little above 212° , scarcely soluble in water, soluble in alcohol and ether, and capable of neutralizing the acids. Given to a cat, it was found by M. Desfosses to operate at first as an emetic, and afterwards as a narcotic. Dr. J. Otto observed, among its most striking effects, a paralytic condition of the posterior limbs of the animals to which it was administered. One grain of the sulphate of *solanina* was sufficient in his hands to destroy a rabbit in six hours. Besides *solanina*, the stalks of the *S. Dulcamara* contain, according to Pfaff, a peculiar principle to which he gave the name of *picroglycion*, indicative of the taste at once bitter and sweet, which it is said to possess. This has been obtained in a crystalline state by Blitz, by the following process. The watery extract is treated with alcohol, the tincture evaporated, the residue dissolved in water, the solution precipitated with subacetate of lead, the excess of this salt decomposed by sulphuretted hydrogen, the liquor then evaporated to dryness, and the residue treated with acetic ether, which yields the principle in the form of small isolated crystals by spontaneous evaporation. Pfaff found also in *Dulcamara*, a vegeto-animal substance, gummy extractive, gluten, green wax, resin, benzoic acid, starch, lignin, and various salts of lime.

Medical Properties and Uses. *Dulcamara* possesses feeble narcotic properties, with the power of increasing the secretions, particularly that of the kidneys and skin. We have observed, in several instances, when the system was under its influence, a dark purplish colour of the face and hands, and at the same time considerable languor of the circulation. Its narcotic effects do not become obvious, unless when it is taken in large quantities. In overdoses it produces nausea, vomiting, faintness, vertigo, and convulsive muscular movements. It has been recommended in various diseases, but is now nearly confined to the treatment of cutaneous eruptions, particularly those of a scaly character, as lepra, psoriasis, and pityriasis. In these complaints it is often decidedly beneficial, especially in combination with minute doses of the antimonials. Its influence upon the secretions is insufficient to account for its favourable effects, and we must be content with ascribing them to an alterative action. It is said to have been beneficially employed in chronic rheumatism and chronic catarrh. Antaphrodisiac properties are ascribed to it by some physicians. (See *Am. Cyc. of Pract. Med.* ii. 23.) We have seen it apparently useful in mania connected with strong venereal propensities. The usual form of administration is that of decoction, of which two

fluidounces may be taken four times a day, and gradually increased till some slight disorder of the head indicates the activity of the medicine. (See *Decoctum Dulcamaræ*.) An extract may also be prepared, of which the dose is from five to ten grains. That of the powder would be from thirty grains to a drachm.

In cutaneous affections a strong decoction is often applied to the skin, at the same time that the medicine is taken internally.

Momordica Elaterium. *Willd. Sp. Plant.* iv. 605; *Woodv. Med. Bot.* p. 192. t. 72.—*Ecballium Elaterium*. *French Codex*, A. D. 1837. The wild or squirting cucumber is a perennial plant, with a large fleshy root, from which proceed several round, thick, rough stems, branching and trailing like the common cucumber, but without tendrils. The leaves are petiolate, large, rough, irregularly cordate, and of a grayish-green colour. The flowers are yellow, and proceed from the axils of the leaves. The fruit has the shape of a small oval cucumber, about an inch and a half long, an inch thick, of a greenish or grayish colour, and covered with stiff hairs or prickles. When fully ripe, it separates from the peduncle, and throws out its juice and seed with considerable force through an opening at the base, where it was attached to the footstalk. The name of squirting cucumber was derived from this circumstance, and the scientific and officinal title is supposed to have had a similar origin, though some authors maintain that the term *elaterium* was applied to the medicine, rather from the mode of its operation upon the bowels, than from the projectile property of the fruit.*

This species of *Momordica* is a native of the South of Europe; and is cultivated in Great Britain, where, however, it perishes in the winter. *Elaterium* is the substance spontaneously deposited by the juice of the fruit, when separated, and allowed to stand. Dr. Clutterbuck of London has proved that it is contained only in the free juice which surrounds the seeds, and which is obtained without expression. The body of the fruit itself, the seeds, as well as other parts of the plant, are nearly or quite inert. When the fruit is sliced or placed upon a sieve, a perfectly limpid and colourless juice flows

* From the Greek *ελατω* I drive, or *ελατης* driver. The word *elaterium* was used by Hippocrates to signify any active purge. Dioscorides applied it to the medicine of which we are treating.

out, which after a short time becomes turbid, and in the course of a few hours begins to deposit a sediment. This, when collected and carefully dried, is very light and pulverulent, of a yellowish-white colour, slightly tinged with green. It is the genuine elaterium, and was found by Clutterbuck to purge violently in the dose of one-eighth of a grain. But the quantity contained in the fruit is exceedingly small. Clutterbuck obtained only six grains from forty cucumbers. Commercial elaterium is a much weaker medicine, owing in part, perhaps, to adulteration, but much more to the mode in which it is prepared. In order to increase the product, the juice of the fruit is often expressed; and there is reason to believe that it is sometimes evaporated so as to form an extract, instead of being allowed to deposit the active matter. The French elaterium is prepared by expressing the juice, clarifying it by rest and filtration, and then evaporating it to a suitable consistence. As the liquid which remains after the deposition of the sediment is comparatively inert, it will be readily perceived that the preparation of the French Codex must be very feeble. The following are the directions of the London College, with which those of the Edinburgh and Dublin Colleges essentially correspond. "Slice ripe wild cucumbers, express the juice very gently, and pass it through a very fine hair sieve; then set it aside for some hours until the thicker part has subsided. Reject the thinner, supernatant part, and dry the thicker part with a gentle heat." As the process is executed at Apothecaries' Hall, the juice, after expression, is allowed to stand for about two hours, when the supernatant liquor is poured off, and the matter deposited is carefully dried, constituting the finest elaterium. Another portion, of a paler colour, is deposited by the decanted liquor. (*Pereira.*) The slight pressure directed is necessary for the extraction of the juice from the somewhat immature fruit employed; and the perfectly ripe fruit cannot be employed; as, in consequence of its disposition to part with its contents, it cannot be carried to market. The medicine is incorrectly denominated by the London and Dublin Colleges *Extractum Elaterii*; being neither an extract, strictly speaking, nor an inspissated juice. The Edinburgh College calls it Elaterium in the Materia Medica list, but inconsistently admits the name of *Extractum Elaterii* in the preparations. In the Pharmacopœia of the United States, it is named simply *Elaterium*. As the plant is not cultivated in this country for medicinal purposes, our Pharmacopœia very properly adopts as officinal, the medicine as it is found in commerce. It is brought chiefly from England; but it is probable that a portion of the elaterium, of which Dr. Pereira speaks as coming from Malta, reaches our market also.

Properties. The best elaterium is in thin flat or slightly curled cakes or fragments, often bearing the impression of the muslin upon which it was dried, of a greenish-gray colour becoming yellowish by exposure, of a feeble odour, and a bitter somewhat acrid taste. It is pulverulent, and inflammable, and so light that it swims when thrown upon water. When of inferior quality, it is sometimes dark-coloured, much curled, and rather hard, either breaking with difficulty or presenting a resinous fracture. The Maltese elaterium is in larger pieces, of a pale colour sometimes without the least tinge of green, destitute of odour, soft, and friable; and not unfrequently presents evidences of having been mixed with chalk or starch. It sinks in water.

Dr. Clutterbuck first observed that the activity of elaterium resided in that portion of it which was soluble in alcohol and not in water. This fact was afterwards confirmed by Dr. Paris, who found that the alcoholic extract, treated with boiling distilled water, and afterwards dried, had the property

of purging in very minute doses, while the remaining portion of the elaterium was inactive. Supposing the substance thus prepared to be the active principle, he gave it the name of *elatin*; but incorrectly, as it consists of at least two distinct ingredients. The subsequent experiments of Mr. Hennel of London, and Mr. Morries of Edinburgh, which appear to have been nearly simultaneous, demonstrated the existence of a crystallizable matter in elaterium, which is probably the active principle of the medicine, and for which Mr. Morries proposed the appropriate name of *elaterin*. According to Mr. Hennel, 100 parts of elaterium contain 44 of elaterin, 17 of a green resin (chlorophylle), 6 of starch, 27 of lignin, and 6 of saline matters. The elatin of Dr. Paris is probably a mixture of elaterin and the green resin or chlorophylle.*

Elaterin, according to Mr. Morries, crystallizes when pure in colourless microscopic rhombic prisms, which have a silky appearance when in mass. It is extremely bitter and somewhat acrid to the taste, insoluble in water and alkaline solutions, soluble in alcohol, ether, and hot olive oil, and sparingly soluble in dilute acids. At a temperature between 300° and 400° it melts, and at a higher temperature is dissipated in thick, whitish, pungent vapour, having an ammoniacal odour. It has no alkaline reaction. It may be easily procured by evaporating an alcoholic tincture of elaterium to the consistence of thin oil, and throwing the residue while yet warm into a weak boiling solution of potassa. The potassa holds the green resin or chlorophylle in solution, and the elaterin crystallizes as the liquor cools. Mr. Hennel obtained it by treating with ether the alcoholic extract procured by the spontaneous evaporation of the tincture. This consists of elaterin and the green resin, the latter of which being much more soluble in ether than the former, is completely extracted by this fluid, leaving the elaterin pure. But as elaterin is also slightly soluble in ether, a portion of this principle is wasted by Mr. Hennel's method. By evaporating the ethereal solution, the green resin is obtained in a separate state. Mr. Hennel states that this was found to possess the purgative property of the elaterium in a concentrated state, as it acted powerfully in a dose less than one-third of a grain. But this effect was probably owing to the presence of a portion of elaterin which had been dissolved by the ether. The late Dr. Duncan of Edinburgh ascertained that the crystalline principle or elaterin produced, in the quantity of $\frac{1}{12}$ th or $\frac{1}{16}$ th of a grain, all the effects of a dose of elaterium. The quantity of elaterin varies exceedingly in different parcels of the drug. Mr. Morries obtained 26 per cent. from the best British elaterium, 15 per cent. from the worst, and only 5 or 6 per cent. from the French; while a portion procured according to the directions of the London College, yielded to Mr. Hennel upwards of 40 per cent. This great diversity in the strength of elaterium renders the substitution of its purgative principle highly desirable.

Choice of Elaterium. The inequality of elaterium depends probably more on diversities in the mode of preparation than on positive adulteration. It should possess all the sensible properties above indicated, as characterizing good elaterium, should not effervesce with acids, and should yield, as directed by the Edinburgh College, from one-seventh to one-fourth of elaterin, when treated in the mode above recommended for procuring that principle.

Medical Properties and Uses. Elaterium is a powerful hydragogue cathartic, and in a large dose generally excites nausea and vomiting. If too

* The substance to which Pelletier gave the name of *chlorophylle*, under the impression that it was a peculiar proximate principle, has been ascertained by that chemist to be a mixture of wax, and a green fixed oil. (*Journ. de Pharm.* xix. 109.)

freely administered, it operates with great violence both upon the stomach and bowels, producing inflammation of these organs, which has in some instances eventuated fatally. It also increases the flow of urine. The fruit was employed by the ancients, and is recommended in the writings of Dioscorides as a remedy in mania and melancholy. Sydenham and his contemporaries considered elaterium highly useful in dropsy; but, in consequence of some fatal results from its incautious employment, it fell into disrepute, and was generally neglected, till again brought into notice by Dr. Ferriar. It is now considered one of the most efficient hydragogue cathartics in the treatment of dropsical diseases, in which it has sometimes proved successful after all other remedies have failed. The full dose of ordinary commercial elaterium is from one to two grains; but as in this quantity it generally vomits, if of good quality, the best mode of administering it is in the dose of a quarter or half a grain repeated every hour till it operates. The dose of Clutterbuck's elaterium is the eighth of a grain. That of elaterin is from the sixteenth to the twelfth of a grain, and is best given in solution. One grain may be dissolved in a fluidounce of alcohol with four drops of nitric acid, and from 30 to 40 minims may be given diluted with water. W.

Gen. Ch. Calyx four-toothed. Petals four, oblong. Stigma four-cornered. Berry drupaceous. Willd.

Some botanists separate from this genus the species which have their fruit in the form of a capsule instead of a nut, and associate them together in a distinct genus with the name of *Icica*. This is recognised by De Candolle.

Most of the trees belonging to these two genera yield, when wounded, a resinous juice analogous to the turpentine, and differing little as procured from the different species. It is not improbable that the drug usually known by the name of *elemi*, though referred by the Colleges to one tree, is in fact derived from several. That known to the ancients is said to have been obtained from Ethiopia, and all the elemi of commerce was originally brought from the Levant. The tree which afforded it was not accurately known, but was supposed to be a species of *Amyris*. Geiger states that it was derived from the *A. Zeilanica*, growing in Ceylon. At present the drug is taken to Europe from Brazil, and is believed to be the product of a plant mentioned by Marcgrav under the name of *icicariba*, and considered by Linnæus as the *Amyris elemifera*. It appears, however, to be properly an *Icica*, and De Candolle denominates it *I. Icariba*. We can find no detailed description of the tree. It has a lofty trunk, with pinnate leaves, consisting of three or five pointed, perforated leaflets, which are smooth on their upper surface, and woolly beneath. It is erroneously stated in some works to be a native of Carolina. The elemi is obtained by incisions into the tree, through which the juice flows and concretes upon the bark.

It is in masses of various consistence, sometimes solid and heavy like wax, sometimes light and porous; unctuous to the touch; diaphanous; of diversified colours, generally greenish with intermingled points of white or

yellow, sometimes greenish-white with brown stains, sometimes yellow like sulphur; fragile and friable when cold; softening by the heat of the hand; of a terebinthinate somewhat aromatic odour, diminishing with age, and said, in some varieties, to resemble that of fennel; of a warm, slightly bitter, disagreeable taste; entirely soluble, with the exception of impurities, in boiling alcohol; and affording a volatile oil by distillation. It consists, according to M. Bonastre, of 60 parts of resin, 24 of a resinous matter soluble in boiling alcohol, but deposited when the liquid cools, 12·5 of volatile oil, 2 of extractive, and 1·5 of acid and impurities. It is sometimes adulterated with colophony and turpentine.

Medical Properties and Uses. Elemi has properties analogous to those of the turpentine; but is exclusively applied to external use. In the United States it is rarely employed even in this way. In the pharmacy of Europe it enters into the composition of numerous plasters and ointments. We are told that it is occasionally brought to this country in small fragments mixed with the coarser kinds of gum Arabic from the Levant and India.

ERGOTA. U.S., Lond., Ed.

Ergot.

“The diseased seeds of *Secale cereale*.” *U.S.* “*Acinula clavus*.” *Lond.* “An undetermined fungus, with degenerated seed of *Secale cereale*.” *Ed.*

Spurred rye; *Secale cornutum*; *Seigle ergoté*, *Fr.*; *Mutterkorn*, *Germ.*

In all the *Graminaceæ* or grass tribe, and in some of the *Cyperaceæ*, the place of the seeds is sometimes occupied by a morbid growth, which, from its resemblance to the spur of a cock, has received the name of *ergot*, adopted from the French. This product is most frequent in the rye, *Secale cereale* of botanists, and having been found, as occurring in that plant, to possess valuable medicinal properties, was adopted in the first edition of the United States Pharmacopœia under the name of *Secale cornutum* or *spurred rye*. In the recent edition, this name has been changed for *Ergota*, in conformity with the nomenclature of the London and Edinburgh Colleges, by whom the medicine was recognised for the first time at the last revision of their official catalogues.

Considerable difference of opinion has existed in relation to the nature of this singular substance. It was at one time generally thought to be merely the seed altered by disease—the morbid condition being ascribed by some to the agency of an insect, by others to excess of heat and moisture. A second opinion considered it a parasitic fungus, occupying the place of the seed. This was entertained by De Candolle, who called the fungus *Sclerotium Clavus*. According to a third and intermediate opinion, the ergot is the seed, diseased and entirely perverted in its nature by the influence of a parasitic fungus, attached to it from the very beginning of its development. This view was put forth by M. Léveillé in a memoir published in the Annals of the Linn. Society of Paris for the year 1826. According to this writer, a soft viscid tubercle may be seen at the earliest stage of the flower, surmounting the germ, the character of which it changes, without preventing its growth. The germ becomes of a dark colour, and increasing in size pushes the tubercle before it, which also expands, and exudes a viscid matter, which spreads over the germ, and drying upon its surface, gives it a thin yellowish coating. The tubercle was considered by M. Léveillé a fungus, and named *Sphacelia segetum*. The more recent observa-

tions of Mr. Quekett, of London, confirm this general view of the nature of ergot; but lead to a different conclusion as to the character of the parasitic plant. According to Mr. Quekett, the beginning of the growth of the ergot is marked by the appearance, about the young grain and its appendages, of multitudes of minute filaments like cobwebs, which run over all its parts, cementing anthers and stigmas together, and of a white coating upon the surface of the grain, from which, upon immersion in water, innumerable minute particles separate, and after a time sink in the fluid. These particles, when examined by the microscope, prove to be the reproductive agents, germs, or *sporidia* of a species of fungus, and may be observed to sprout and propagate in various ways under favourable circumstances. Their length, upon the average, is about the four-thousandth of an inch. The filaments are the results of the growth of these singular germs. The *sporidia* and filaments do not increase with the increase of the ergot; and when this has projected beyond the paleæ and become visible, it has lost a portion of its white coating and presents a dark violet colour. It now increases with great rapidity, and attains its full size in a few days. When completely developed, it exhibits very few of the filaments or *sporidia* upon its surface. But Quekett believes that the germs of the fungus emit their filaments through the tissue of the ergot when young and tender, and that, as this increases, it is made up partly of the diseased structure of the grain, and partly of the fungous matter. The fungus was named by Quekett *Ergotætia abortifaciens*. This view of the nature and cause of ergot is strongly supported by the asserted facts, that the microscopic fungus has an existence independent of the morbid grain, being found in various other parts of the plant, and growing even when entirely separated from it, and that the *sporidia* or white dust upon the surface of ergot, if applied to the seeds of certain Graminaceæ before germination, or sprinkled in the soil at the roots of the plants after they have begun to grow, will give rise to ergotized fruit.* That the ergot is not itself a peculiar fungus, but the perverted grain, is evinced by the frequent remains of the stigma upon its summit, by the scales at its base, and by the circumstance that in some instances only a portion of the seed is ergotized. How far its peculiar medical properties may depend upon the morbid substance of the grain, and how far on the fungous matter associated with it, has not been determined. (See *Am. Journ. of Pharm.* xi. 116 and 237—and *Med. Exam. N. S.* i. 62.)

The ergot usually projects out of the glume or husk beyond the ordinary outline of the spike or ear. In some spikes the place of the seeds is wholly occupied by the ergot, in others only two or three spurs are observed. It is stated that this substance is much more energetic when collected before than after harvest. Rye has generally been thought to be most subject to the disease in poor and wet soils, and in rainy seasons; and intense heat succeeding continued rains is said to favour its development, especially if these circumstances occur at the time the flower is forming. It is now, however, asserted that moisture has little or nothing to do with its production. (*Pereira*.) It should not be collected until some days after it has

* Wiggers observed that the white dust on the surface of ergot occasioned the same disease in other plants, when sprinkled in the soil about the roots; and Quekett found that the seeds of rye immersed in water impregnated with the *sporidia* from ergot, and afterwards allowed to germinate, produced plants on every one of which there were some ears possessing ergotted grains. (*Med. Gazette*, October, 1841.) It is true that Dr. Wright failed in obtaining the same effects, though he sowed powdered ergot with rye, watered the growing plants daily with water in which ergot had been steeped, and applied the powder to the growing ears. (*Ed. Med. and Surg. Journ.* January, 1841.) But this failure ought not to invalidate the positive results obtained by others.

begun to form; as, according to M. Bonjean, if gathered on the first day of its formation, it does not possess the poisonous properties which it exhibits when taken on the sixth day. (*Pharmaceutical Transactions*, Jan. 1842, from *Journ. de Chim. Med.*)

Properties. Ergot is in solid, brittle yet somewhat flexible grains, from a third of an inch to an inch and a half long, from half a line to three lines in thickness, cylindrical or obscurely triangular, tapering towards each end, obtuse at the extremities, usually curved like the spur of a cock, marked with one or two longitudinal furrows, often irregularly cracked or fissured, of a violet-brown colour and often somewhat glaucous externally, yellowish-white, or violet-white within, of an unpleasant smell when in mass resembling that of putrid fish, and of a taste which is at first scarcely perceptible, but ultimately disagreeable and slightly acrid. Under the microscope, the surface appears more or less covered with sporidia, which occasion its glaucous aspect; and the interior structure is found to be composed of minute roundish cells, containing, according to Quekett, particles of oil. Ergot yields its virtues to water and alcohol. The aqueous infusion or decoction is claret-coloured, and has an acid reaction. It is precipitated by the acetate and subacetate of lead, nitrate of silver, and tincture of galls; but affords with iodine no evidence of the presence of starch.

Ergot has been analyzed by Vauquelin, Winkler, a German chemist named Wiggers, Wright, and several others. The results obtained by Wiggers and Wright are most deserving of notice. According to the former, ergot contains 35.0 per cent. of a peculiar fixed oil; 1.04 of a peculiar, white, crystallizable, very soft fatty matter; 0.75 of cerin; 46.18 of a substance analogous to fungin, or the fleshy substance of mushrooms; 1.24 of *ergotin*; 7.76 of a substance resembling osmazome; 1.55 of a peculiar saccharine matter; 2.32 of gummy extractive combined with an azotized colouring principle; and 1.46 of albumen; besides saline and earthy matters in minute proportion. *Ergotin* was supposed by Wiggers to be the active principle. It is reddish-brown, of a peculiar nauseous odour and a bitter slightly acrid taste, soluble in alcohol, but insoluble in water or ether. It was obtained by digesting ergot in ether and afterwards in alcohol, evaporating the alcoholic solution, and treating the extract thus obtained with water, which left the *ergotin* undissolved. It was given with fatal effects to a hen; but much ampler observation is necessary to establish its claim to be considered as the active principle. Dr. Christison, though following the process of Wiggers, was unable to obtain *ergotin*, and Dr. Wright was equally unsuccessful. According to the last mentioned chemist, ergot contains 31.0 per cent. of oil, 11.4 of fungin, 26.0 of altered starch, 9.0 of mucilage, 7.0 of gluten, 5.5 of vegetable osmazome, 3.5 of colouring matter, and 3.1 of salts with free phosphoric acid. Dr. Wright, after careful investigation, came to the conclusion that the activity of the medicine resides in its fixed oil, which has accordingly been introduced into practice as a substitute for ergot. The *oil of ergot*, when obtained from grains recently collected, is, according to Dr. Wright, often quite free from colour; but as usually prepared, it is reddish-brown. It has a disagreeable, somewhat acrid taste, is lighter than water, and is soluble in alcohol and alkaline solutions. It is prepared by forming an ethereal tincture of ergot by the process of displacement, and evaporating the ether with a gentle heat. (*Ed. Med. and Surg. Journ.* for 1839-40.) The conclusions of Dr. Wright in relation to the action of this oil upon the system have been confirmed by the experiments and observations of others; and there can scarcely be a doubt that its effects

are identical with those of ergot. It may however be said, in all probability, rather to contain the active principle of ergot, than itself to constitute that principle. Thus, it is asserted that the oil obtained by simple expression produces on animals none of the effects which constantly result from that obtained by means of ether. (*Journ. de Pharm. N. S.* i. 183.) The opinion of M. Bonjean, that there are two active principles in ergot, the oil which is poisonous, and another resident in the watery extract, and possessing anti-hemorrhagic properties without being in the least degree poisonous, requires confirmation.

Ergot, when perfectly dry and kept in well-stopped bottles, will retain its virtues for a considerable time; but exposed to air and moisture it speedily undergoes chemical changes and deteriorates. It is, moreover, apt to be attacked by a minute worm, which consumes the interior of the grain, leaving merely the exterior shell and an excrementitious powder. This insect is sometimes found in the ergot before removal from the plant. (Muller, *Am. Journ. of Pharm.* x. 269.) In the state of powder, the medicine still more readily deteriorates. It is best, as a general rule, to renew it, if possible, every year or two.

Medical Properties and Uses. Given in small doses, ergot produces, in the system of the male, no obvious effects; but in the female, exhibits a strong tendency to the uterus, upon the contractile property of which it operates with great energy. It is perhaps the only medicine which specifically promotes contraction in this organ. In the quantity of half a drachm or a drachm it often occasions nausea or vomiting, and in still larger doses produces a sense of weight and pain in the head, giddiness, dilatation of the pupils, delirium, and even stupor, proving that it possesses narcotic properties. It is said also to excite febrile symptoms; but our own observation coincides with that of authors who ascribe to it the power of reducing the frequency of the pulse. We have seen this effect produced by it in a remarkable degree, even without nausea. Its long continued and copious use is highly dangerous, even when no immediate effects are perceptible. Terrible and devastating epidemics in different parts of the continent of Europe, particularly in certain provinces of France, have long been ascribed to the use of bread made from rye contaminated with this degenerate grain. Dry gangrene, typhus fever, and disorder of the nervous system attended with convulsions, are the forms of disease which have been observed to follow the use of this unwholesome food. It is true that ergot has been denied to be the cause; but accurate investigations made by competent men upon the spot where the epidemics have prevailed, together with the result of experiments made upon inferior animals, leave no room for reasonable doubt upon the subject. Very large quantities are required for immediate poisonous effects. From two to eight drachms have been given at one dose to man without very serious results, and three ounces, according to Dr. Wright, were required to kill a small dog. Death from single doses, in inferior animals, is preceded by symptoms indicating irritation of stomach and bowels, great muscular prostration, loss of sensation, and sometimes slight spasms.

The most important remedial application of ergot is founded on its power of promoting the contraction of the uterus. On the continent of Europe, in various parts of Germany, France, and Italy, it has long been empirically employed by midwives for this purpose; and its German name of *mutterkorn* implies a popular acquaintance with its peculiar powers. But the attention of the medical profession was first called to it by a letter from Dr. Stearns of Saratoga county, in the state of New York, addressed to

Dr. Ackerly, A.D. 1807, and published in the eleventh volume of the New York Medical Repository. Since that period the journals have teemed with communications attesting its efficacy in facilitating parturition; and, though it has failed in the hands of some physicians, the general opinion of the profession is so decidedly in its favour, that it may now be considered among the established articles of the *materia medica*. When it has proved wholly inefficient, the result is ascribable to peculiarity of constitution in the individual, or to the inferior character of the particular parcel employed. In its operation upon the pregnant uterus it produces a constant unremitting contraction and rigidity, rather than that alternation of spasmodic effort and relaxation which is observable in the natural process of labour. Hence, unless the os uteri and external parts are sufficiently relaxed, the medicine would be likely to produce injury to the child by the incessant pressure which it maintains. Such in fact has been the observation of numerous practitioners, and the death of the infant is thought not unfrequently to result from the injudicious employment of the medicine. The cases to which it is thought to be especially adapted are those of lingering labour, when the os uteri is sufficiently dilated, and the external passages sufficiently relaxed, when no mechanical impediment is offered to the passage of the child, and the delay is ascribable solely to want of energy in the uterus. Other cases are those in which the death of the fœtus has been ascertained, and when great exhaustion or dangerous constitutional irritation imperiously calls for speedy delivery. The remedy may also be given to promote the expulsion of the placenta, to restrain inordinate hemorrhage after delivery, and to hasten the discharge of the fœtus in protracted cases of abortion. In women subject to dangerous flooding, a dose of ergot given immediately before delivery is said to have the happiest effects. It has also been recommended for the expulsion of coagula of blood, polypi, and hydatids from the uterine cavity. It has been accused of producing puerperal convulsions, hour-glass contraction of the uterus, and hydrocephalus in the new-born infant. (Dr. Catlett, *Ed. Med. & Surg. Journ. Jan. 1842.*) In menorrhagia and uterine hemorrhage, unconnected with pregnancy, the medicine has long been empirically employed, and is now found highly useful in the hands of regular practitioners. Its use has even been extended to hemorrhages from other organs, and with reputed good effect. Cases of hemorrhage from the lungs are recorded in which ergot has proved highly beneficial. We have seen it promptly effectual after all the usual means had failed. May it not have the power of producing contraction in the capillaries in general, or of interfering in some other way with the circulation of the blood in these vessels, as by the exertion of a direct sedative or paralyzing influence upon them? We might in this way account for the dry gangrene which results from its abuse, as well as for its influence in restraining hemorrhage. It has also been employed in amenorrhœa, but not with encouraging success. Gonorrhœa, gleet, leucorrhœa, dysmenorrhœa, chronic dysentery, paraplegia, paralysis of the bladder, and intermittent fever, are among the complaints in which it has been recommended.

Ergot is usually given in substance, infusion, or decoction. The dose of the powder to a woman in labour is fifteen or twenty grains, to be repeated every twenty minutes, till its peculiar effects are experienced, or till the amount of a drachm has been taken. Of an infusion made in the proportion of a drachm of the ergot to four fluidounces of water, one-third may be given for a dose, and repeated with the same interval. For other purposes the dose of the medicine is ten or fifteen grains, repeated three times a day, and gradually increased, but not continued for a great length of time. In urgent cases of hemorrhage, the dose may be repeated every two hours,

or oftener if necessary. A wine of ergot is directed by the United States Pharmacopœia, and should supersede the tinctures formerly used, which are of uncertain strength. (See *Vinum Ergotæ*.) The oil of ergot, prepared by means of ether, as already described, was given by Dr. Wright in the dose of from twenty to fifty drops, diffused in cold water, warm tea, or weak spirit and water. He employed it not only as an aid to parturition and in uterine affections, but also, with marked advantage, in diarrhœa, in the dose of ten drops every three hours, and in gastric irritability and spasm. It may be kept for a long time unimpaired in a well-stopped bottle, in a cool, dark place. Its strength is diminished by an elevated temperature, or prolonged exposure to the sun. The size of the dose is sufficient proof that the oil is not the active principle of ergot, but only holds that principle in solution.

Ergot has been employed externally. Dr. Müller found it to check the bleeding from large divided arteries; and Dr. Wright states that either in powder or infusion it has a prompt effect in arresting hemorrhage. It is recommended by the latter practitioner as an injection in uterine hemorrhage. It should be used, however, with some caution; as the powder applied to abraded surfaces has produced sloughing in the lower animals.

Ergot should be powdered only when wanted for use.

ERIGERON CANADENSE. *U. S. Secondary.*

Canada Fleabane.

“The herb of *Erigeron Canadense*.” *U. S.*

ERIGERON. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ-Asteroidæ, *De Cand.* Asteraceæ, *Lindley*.

Gen. Ch. *Calyx* imbricated, sub-hemispherical, in fruit often reflected. *Florets of the ray* linear, very narrow, numerous. *Receptacle* naked. *Pappus* double, exterior minute, interior pilose, of few rays. *Nuttall*.

Erigeron Canadense. Willd. *Sp. Plant.* iii. 1954. This is an indigenous annual plant, with a stem from two to six feet high, covered with stiff hairs, and divided into numerous branches. The leaves are linear lanceolate, and edged with hairs; those at the root are dentate. The flowers are very small, numerous, white, and arranged in terminal panicles. They differ from those of the other species of *Erigeron* in having an oblong calyx, the rays very minute and more numerous than the florets of the disk, and the seed down simple. Hence by some botanists the plant is placed in a sub-genus with the title *Cænotus*. Another variety of the *E. Canadense*, which Mr. Nuttall makes a distinct species, with the title *E. pusillum*, is not more than from four to six inches high, and has an erect smooth stem, less branched than the preceding, with all its leaves entire, and scabrous on the margin. The panicle is simple, and the peduncles filiform, nearly naked, divaricate, each bearing two or three flowers.

Canada fleabane is very common throughout the northern and middle sections of the United States, and has become naturalized in many parts of Europe. It abounds in neglected fields, and blooms in July and August. The plant, all parts of which are medicinal, should be collected while in flower. The leaves and flowers are said to possess its peculiar virtues in greatest perfection.

This species of *Erigeron* has an agreeable odour, and a bitterish, acrid, somewhat astringent taste. Among its constituents, according to Dr. De Puy, are bitter extractive, tannin, gallic acid, and volatile oil. Both alcohol

and water extract its virtues. Its acrimony is diminished by decoction, probably in consequence of the escape of the oil.

Medical Properties and Uses. From the observations of Dr. De Puy, it appears to be diuretic, tonic, and astringent; and has been found useful in dropsical complaints and diarrhœa. It may be given in substance, infusion, tincture, or extract. The dose of the powder is from thirty grains to a drachm; of an infusion prepared in the proportion of an ounce of the plant to a pint of boiling water, from two to four fluidounces; of the aqueous extract from five to ten grains. In each case the dose should be repeated every two or three hours. W.

ERIGERON HETEROPHYLLUM. U. S. Secondary.

Various-leaved Fleabane.

“The herb of *Erigeron heterophyllum*.” U. S.

ERIGERON PHILADELPHICUM. U. S. Secondary.

Philadelphia Fleabane.

“The herb of *Erigeron Philadelphicum*.” U. S.

ERIGERON. See ERIGERON CANADENSE.

1. *Erigeron heterophyllum*. Willd. *Sp. Plant.* iii. 1956; Barton, *Am. Med. Bot.* i. 231. This is a biennial herbaceous plant, belonging both to North America and Europe. It has a branching root, from which proceed several erect, roundish, striated pubescent stems, much divided near the top, and rising two or three feet in height. The lower leaves are ovate, acute, deeply toothed, and supported upon long winged footstalks; the upper are lanceolate, acute, deeply serrate in the middle, and sessile; the floral leaves are lanceolate and entire; all, except those from the root, are ciliate at the base. The flowers are in terminal corymbs. The florets of the disk are yellow, those of the ray numerous, very slender, and of a white, pale blue, or pale purple colour. The flowering period is from June to October.

Erigeron Philadelphicum. Willd. *Sp. Plant.* iii. 1957; Barton, *Med. Bot.* i. 227. The Philadelphia fleabane is perennial and herbaceous, with a branching yellowish root, and from one to five erect stems, which rise two or three feet in height, and are much branched at top. The whole plant is pubescent. The lower leaves are ovate lanceolate, nearly obtuse, ciliate on the margin, entire or marked with a few serratures, and supported on very long footstalks; the upper are narrow, oblong, somewhat wedge-shaped, obtuse, entire, sessile, and slightly embrace the stem; the floral leaves are small and lanceolate. The flowers are numerous, radiate, and disposed in a paniced corymb, with long peduncles bearing from one to three flowers. They resemble those of the preceding species in colour, and make their appearance about the same period.

We include these two species under one head, because they grow together, possess identical medical properties, and are indiscriminately employed. They are found in various parts of the United States, and abound in the fields about Philadelphia, where they are known and used under the common though inaccurate name of *scabious*. The whole herb is used, and should be collected while the plants are in flower. It has an aromatic odour, and a slightly bitterish taste, and imparts its properties to boiling water.

Medical Properties and Uses. Fleabane is diuretic, without being offensive to the stomach. It is a favourite remedy with some highly respectable practitioners of Philadelphia in gravel and other nephritic diseases, and has been employed with advantage in dropsy. By the late Dr. Wistar it was recommended in hydrothorax complicated with gout. When the obstinate character and long continuance of certain dropsical affections are considered, the advantage must appear obvious, of having numerous remedies calculated to mitigate the symptoms without exhausting the strength of the patient; so that when one has lost its power from repetition, we may appeal to another with some prospect of benefit. On this account it is that fleabane is worthy of the notice of the profession. It cannot be relied on for the cure of dropsy.

It is most conveniently administered in infusion or decoction, of which a pint, containing the virtues of an ounce of the herb, may be given in twenty-four hours. W.

ERYNGIUM. U.S. Secondary.

Button Snakeroot.

“The root of *Eryngium aquaticum*.” U. S.

ERYNGIUM. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Apiaceæ or Umbelliferæ.

Gen. Ch. Flowers capitate. *Involucrum* many-leaved. Proper *Calyx* five-parted, superior, persistent. *Corolla* of five petals. *Receptacle* foliaceous, segments acute or cuspidate. *Fruit* bipartile. *Nuttall.*

Eryngium aquaticum. Willd. *Sp. Plant.* i. 1357. The *button snakeroot*, or *water eryngo*, is an indigenous herbaceous plant, with a perennial tuberous root, and a stem two or three feet high, sometimes, according to Pursh, six feet, generally branching by forks, but trichotomous above. The leaves are very long, linear-lanceolate on the upper part of the stem, sword-shaped below, with bristly spines at distant intervals upon their margin. The floral leaves are lanceolate and dentate. The flowers are white or pale, and disposed in globose heads, with the leaflets of the involucre shorter than the head, and, like the scales of the receptacle, entire. This plant is found in low wet places, from Virginia to Carolina. Its period of flowering is August.

The root, which is the medicinal portion, has a bitter, pungent, aromatic taste, provoking, when chewed, a flow of saliva. It is diaphoretic, expectorant, in large doses occasionally emetic; and is used by some physicians in decoction as a substitute for seneka. (*Bigelow.*) We are told in Barton’s “Collections,” that it is nearly allied to the *contrayerva* of the shops. W.

ERYTHRONIUM. U.S. Secondary.

Erythronium.

“The root and herb of *Erythronium Americanum*.” U. S.

ERYTHRONIUM. *Sex. Syst.* Hexandria Monogynia.—*Nat. Ord.* Liliaceæ.

Gen. Ch. *Calyx* none. *Corolla* inferior, six-petalled; the three inner petals with a callous prominence on each edge near the base. *Bigelow.*

Erythronium Americanum. Muhl. *Catalogue* 84; *Bigelow, Am. Med. Bot.* iii. 151.—*E. lanceolatum*. Pursh, p. 230. This is an indigenous pe-

rennial bulbous plant, sometimes called, after the European species, *dog's tooth violet*. The bulb (cormus), which is brown externally, white and solid within, sends up a single naked slender flower-stem, and two smooth lanceolate nearly equal leaves, sheathing at their base, with an obtuse callous point, and of a brownish-green colour diversified by numerous irregular spots. The flower is solitary, nodding, yellow, with oblong lanceolate petals obtuse at the point, a club-shaped undivided style, and a three-lobed stigma.

The *Erythronium* grows in woods and other shady places throughout the Northern and Middle States. It flowers in the latter part of April or early in May. All parts of it are active.

In the dose of twenty or thirty grains, the recent bulb acts as an emetic. The leaves are said to be more powerful. The activity of the plant is diminished by drying. So far as we are at present acquainted with its virtues, it may be considered a useless addition to the *Materia Medica*. Having, however, been adopted in the original edition of the *Pharmacopœia*, it was deemed best, upon the revision of that work, not to expunge it from the catalogue till it had undergone a longer period of trial. W.

EUPATORIUM. U.S.

Thoroughwort.

“The tops and leaves of *Eupatorium perfoliatum*.” U.S.

EUPATORIUM. *Sex. Syst.* Syngenesia *Æqualis*.—*Nat. Ord.* Compositæ-Eupatoriaceæ, *De Cand.* Asteraceæ, *Lindley*.

Gen. Ch. Calyx simple or imbricate, oblong. Style long and semi-bifid. Receptacle naked. Pappus pilose, or more commonly scabrous. Seed smooth and glandular, quinquestriate. *Nuttall*.

Of this numerous genus, comprising not less than thirty species within the limits of the United States, most of which probably possess analogous medical properties, the *E. perfoliatum* alone now holds a place in our national *Pharmacopœia*. The *E. purpureum* and *E. teucrifolium* were originally in the *Secondary List*, but were discarded at the last revision of the *Pharmacopœia*. They merit, however, a brief notice here, if only from their former officinal rank.

Eupatorium purpureum or *gravel root*, is a perennial herbaceous plant, with a purple stem, five or six feet in height, and furnished with ovate lanceolate, serrate, rugosely veined, slightly scabrous, petiolate leaves, placed four or five together in the form of whorls. The flowers are purple, and consist of numerous florets contained in an eight-leaved calyx. It grows in swamps and other low grounds, from Canada to Virginia, and flowers in August and September. The root, which is the part used, has, according to Dr. Bigelow, a bitter, aromatic, and astringent taste, and is said to operate as a diuretic. Its vulgar name of gravel root indicates the popular estimation of its virtues.

Eupatorium teucrifolium (Willd. *Sp. Plant.* iii. 1753), *E. pilosum* (Walt. *Flor. Car.* 199), *E. verbenæfolium* (Mich. *Flor. Am.* ii. 98), commonly called *wild horehound*, is also an indigenous perennial, with an herbaceous stem, which is about two feet high, and supports sessile, distinct, ovate, acute, scabrous leaves, of which the lower are coarsely serrate at the base, the uppermost entire. The flowers are small, white, composed of five florets within each calyx, and arranged in the form of a corymb. The plant grows in low wet places from New England to Georgia, and is very abundant in the Southern States. It is in flower from

August to November. The whole herb is employed. In sensible properties it corresponds with the *E. perfoliatum*, though less bitter and disagreeable. It is said to be tonic, diaphoretic, diuretic, and aperient; and in the South has been much employed as a domestic remedy in intermittent and remittent fevers. Dr. Jones, formerly president of the Georgia Medical Society, was the first to make its properties known to the profession. It is usually administered infused in water. One quart of the infusion, containing the virtues of an ounce of the plant, may be given in separate portions during the day.

The *E. Cannabinum* of Europe, the root of which was formerly used as a purgative; and the *E. Aya-pana* of Brazil, the leaves of which at one time enjoyed a very high reputation as a remedy in numerous diseases, have fallen into entire neglect. The *Aya-pana* is an aromatic bitter, with the medical properties of the *E. perfoliatum* in an inferior degree.

Eupatorium perfoliatum. Willd. *Sp. Plant.* iii. 1761; Bigelow, *Am. Med. Bot.* i. 33; Barton, *Med. Bot.* ii. 125. The *thoroughwort*, or, as it is perhaps more frequently called, *boneset*, is an indigenous perennial plant, with numerous herbaceous stems, which are erect, round, hairy, from two to five feet high, simple below, and trichotomously branched near the summit. The character of the leaves is peculiar, and serves to distinguish the species at the first glance. They may be considered either as perforated by the stem, *perfoliate*, or as consisting each of two leaves joined at the base, *connate*. Considered in the latter point of view, they are opposite and in pairs, which decussate each other at regular distances upon the stem; in other words, the direction of each pair is at right angles with that of the pair immediately above or beneath it. They are narrow in proportion to their length, broadest at the base where they coalesce, gradually tapering to a point, serrate, much wrinkled, paler on the under than the upper surface, and beset with whitish hairs which give them a grayish-green colour. The uppermost pairs are sessile, not joined at the base. The flowers are white, numerous, supported on hairy peduncles, in dense corymbs, which form a flattened summit to the plant. The calyx, which is cylindrical and composed of imbricated, lanceolate, hairy scales, encloses from twelve to fifteen tubular florets, having their border divided into five spreading segments. The anthers are five in number, black, and united into a tube, through which the bifid filiform style projects above the flower.

This species of *Eupatorium* inhabits meadows, the banks of streams, and other moist places, growing generally in bunches, and abounding in almost all parts of the United States. It flowers from the middle of summer to the latter end of October. All parts of it are active; but the herb only is official.

It has a faint odour, and a strongly bitter somewhat peculiar taste. The bitterness and probably the medical virtues of the plant reside in an extractive matter, which is readily taken up by water or alcohol. No accurate analysis of thoroughwort has been made since the recent improvements in vegetable chemistry.

Medical Properties and Uses. Thoroughwort is tonic, diaphoretic, and in large doses emetic and aperient. It is said to have been employed by the Indians in intermittent fever, and has proved successful in the hands of several regular practitioners. The general experience, however, is not in its favour, in that complaint. We have seen it effectual in arresting intermittents when given freely in warm decoction, immediately before the expected recurrence of the paroxysm; but it operated in this instance by its emetic rather than its tonic power. The medicine has also

been used as a tonic and diaphoretic in remittent and typhoid fevers, and is said to have been productive of advantage in yellow fever. Given in warm infusion, so as to produce vomiting or copious perspiration, in the commencement of catarrh, it will frequently arrest that complaint. It has even been recommended as a diaphoretic in inflammatory rheumatism; and may prove serviceable, if administered in the absence of general arterial excitement. As a tonic it has been given with advantage in dyspepsia, general debility, and other cases in which the simple bitters are employed.

With a view to its tonic effect, it is best administered in substance, or in cold infusion. The dose of the powder is twenty or thirty grains, that of the infusion a fluidounce, frequently repeated. (See *Infusum Eupatorii*.) When the diaphoretic operation is required in addition to the tonic, the infusion should be administered warm, and the patient remain covered in bed. As an emetic and cathartic, a strong decoction, prepared by boiling an ounce with three half pints of water to a pint, may be given in doses of one or two gills, or more.

Off. Prep. Infusum Eupatorii, U. S.

W.

EUPHORBIA COROLLATA. U. S. Secondary.

Large-flowering Spurge.

“The root of *Euphorbia corollata*.” U. S.

EUPHORBIA. *Sex. Syst.* Dodecandria Trigynia, Linn.; Monœcia Monadelphica, Michaux.—*Nat. Ord.* Euphorbiaceæ.

Gen. Ch. Involucrum caliciform, eight to ten toothed, exterior alternate dentures glanduloid or petaloid. *Stamina* indefinite, twelve or more, rarely less; *filaments* articulated. *Receptacle* squamose. *Female flower* solitary, stipitate, naked. *Capsule* three-grained. Nuttall.

In the flower of the *Euphorbiæ*, the stamina are arranged two or more together, in distinct parcels, which correspond in number with the inner segments of the calyx. These parcels were considered by Michaux as distinct male florets; while the central stipitate germ, with its three bifid styles, was considered as a distinct female floret, and the calyx took the name of an involucre. He accordingly placed the genus in the class and order *Monœcia Monadelphia*, and in this respect has been followed by most American botanists. The genus *Euphorbia* contains very numerous species, which have the common property of yielding a milky juice. They are herbaceous or shrubby, with or without leaves; and the leafless species, which are chiefly confined to the African deserts, have fleshy, naked, or spiny stems, resembling the genus *Cactus*. They nearly all afford products which act powerfully as emetics and cathartics, and in over-doses give rise to dangerous if not fatal prostration, with symptoms of inflamed gastro-intestinal mucous membrane. Their milky juice, which concretes on exposure to the air, usually possesses these properties in a high degree, and, in addition, that of powerfully irritating the skin when externally applied. Two species only are acknowledged in our national Pharmacopœia, the *E. corollata* and *E. Ipecacuanha*, which are both indigenous. The *E. hypericifolia*, which is also indigenous, has been very highly commended as a remedy in dysentery after due depletion, diarrhœa, menorrhagia, and leucorrhœa, by Dr. W. Zollickoffer of Baltimore. He infuses half an ounce of the dried leaves in a pint of boiling water, and gives half a fluidounce every hour in dysentery till the symptoms begin to yield, the same quantity after every evacuation in diarrhœa, and two fluidounces morning, noon, and

night in menorrhagia and fluor albus. The herb, according to Dr. Zollicoffer, is at first sweetish, afterwards harsh and astringent to the taste, and from his experiments appears to contain tannin. Its effects upon the system are those of an astringent and feeble narcotic. It differs, therefore, considerably, both in sensible and medicinal properties, from most of the other species of *Euphorbia*. (*Am. Journ. of the Med. Sciences*, xi. 22.) In a subsequent communication by the same author, it is stated that the *E. maculata* possesses similar properties with the *E. hypericifolia*. (*Ibid.* N. S. iii. 125.)

Euphorbia Corollata. Willd. *Sp. Plant.* ii. 916; Bigelow, *Am. Med. Bot.* iii. 119. The *blooming* or *large-flowering spurge*, in common language frequently called *milk-weed*, is a tall erect plant, with a large, perennial, branching, yellowish root, which sends up several stems from two to five feet in height, round and generally simple. The leaves, which stand irregularly upon the stem, and without footstalks, are oblong, obovate, wedge-form or linear, flat or revolute at the margin, smooth in some plants, and hairy in others. The flowers are disposed upon a large terminal umbel, with a five-leaved involucre, and five trifid and dichotomous rays, at each fork of which are two oblong bractes. The calyx is large, rotate, white, with five obtuse segments closely resembling a corolla, from which the species has been named. At the base of these divisions are five interior smaller segments, which are described as nectaries by many systematic writers, while the larger are considered as belonging to a real corolla. The stamens are twelve, evolving gradually, with double anthers. Many flowers have only stamens. The pistil, when existing, is stipitate, nodding, rounded, with three bifid styles. The fruit is a smooth, three-celled, three-seeded capsule.

The plant grows in various parts of the United States, from Canada to Florida, and abounds in Maryland and Virginia. It prefers a dry, barren, and sandy soil, seldom growing in woods or on the borders of streams. Its flowers appear in July and August. The root is the only part used.

This, when full grown, is sometimes an inch in thickness, and two feet in length. It is without unpleasant taste, producing only a sense of heat a short time after it has been taken. The medical virtues are said to reside in the cortical portion, which is thick, and constitutes two-thirds of the whole root. They are taken up by water and alcohol, and remain in the extract formed by the evaporation of the decoction or tincture.

Medical Properties and Uses. In a full dose, the root of the *E. corollata* operates actively and with sufficient certainty as an emetic, producing ordinarily several discharges from the stomach, and not unfrequently acting with considerable energy upon the bowels. In quantities insufficient to vomit, it excites nausea, almost always followed by brisk purging. In still smaller doses it is diaphoretic and expectorant. It cannot, however, like ipecacuanha, be given largely in cases of insensibility of stomach, without endangering hypercatharsis with inflammation of the mucous coat of the stomach and bowels. It is in fact greatly inferior to this emetic in mildness, while it is no less inferior to the tartarized antimony in certainty. It is objectionable as a purge, in consequence of the nausea which it occasions, when given in cathartic doses. Dr. Zollicoffer of Baltimore was the first to introduce it to the particular notice of the medical profession. It is little prescribed, and seldom kept in the shops. The dose of the dried root as an emetic is from ten to twenty grains, as a cathartic from three to ten grains. The recent root, bruised and applied to the skin, produces vesication. W.

EUPHORBIA IPECACUANHA. U. S. Secondary.

Ipecacuanha Spurge.

“The root of *Euphorbia Ipecacuanha*.” U. S.

EUPHORBIA. See EUPHORBIA COROLLATA.

Euphorbia Ipecacuanha. Willd. *Sp. Plant.* ii. 900; Barton, *Med. Bot.* i. 211; Bigelow, *Am. Med. Bot.* iii. 108. The *ipecacuanha spurge*, or, as it is sometimes called, *American ipecacuanha*, is a singular plant, varying so much in the shape and colour of its leaves, and in its whole aspect, that mere individual peculiarities might without care be attributed to a real specific difference. The root is perennial, of a yellowish colour, irregular, and very large, penetrating sometimes to the depth of six or seven feet in the sand, and in its thickest part measuring, when full grown, from three-quarters of an inch to one inch and a half in diameter. The stems are numerous, herbaceous, erect or procumbent, smooth, dichotomous, jointed at the forks, white under the ground, red, pale-green, or yellow above, sometimes almost buried in the sand, usually forming thick low bunches upon its surface. The leaves are opposite, sessile, entire, smooth, generally oval, but sometimes round, obovate, or even lanceolate, or linear. They are small early in the spring, and increase in size with the age of the plant. Their colour varies from green to crimson. The flowers are solitary, and stand on long axillary peduncles. The calyx is spreading, with five exterior obtuse segments, and the same number of inner, smaller segments or nectaries. The fertile flowers have a roundish, drooping, pedicelled germ, crowned with six revolute stigmas. The capsule is three-celled, and contains three seeds.

The *E. Ipecacuanha* is indigenous, growing in pine barrens and other sandy places in the Middle and Southern States, especially along the seaboard, and abundant in New Jersey on the bank of the Delaware. It blooms from May to August. The root, which is the officinal portion, is, according to Dr. Barton, equally efficacious at whatever period collected.

The dried root is light and brittle, of a grayish colour externally, white within, inodorous, and of a sweetish not unpleasant taste. Its active principle has not been isolated. Dr. Bigelow inferred from his experiments, that it contained caoutchouc, resin, gum, and probably starch.

Medical Properties and Uses. *Ipecacuanha spurge* is an energetic, tolerably certain emetic, rather milder than the *E. corollata*, but, like that, disposed to act upon the bowels, and liable, if given in over doses, to produce excessive nausea and vomiting, general prostration, and alarming hypercatharsis. It is therefore wholly unfit to supersede *ipecacuanha*. In small doses it is diaphoretic. The specific name of the plant indicates that the emetic property of the root has been long known. The late professor Barton alludes to it in his “Collections;” but it did not come into general notice till after the publication of Dr. W. P. C. Barton’s *Medical Botany*. Dr. Hewson of Philadelphia informed us, that this emetic was the subject of an inaugural essay by Dr. Royal, and that experiments conducted with it among the convicts in the Penitentiary proved it to be advantageously available for all the purposes of an emetic; while, in consequence of its want of nauseous taste, it seemed to answer even better than *ipecacuanha* as an expectorant and diaphoretic. The dose of the powdered root is from ten to fifteen grains.

W.

EUPHORBIIUM. Lond., Ed.*Euphorbium.*

“*Euphorbia officinarum. Gummi-resina.*” Lond. “Concrete resinous juice of undetermined species of *Euphorbia.*” Ed.

Off. Syn. EUPHORBIA CANARIENSIS. Gummi-resina. Dub.

Euphorbe, Fr.; Euphorbium, Germ.; Euforbio, Ital., Span.

EUPHORBIA. See EUPHORBIA COROLLATA.

Euphorbium is obtained from one or more species of *Euphorbia*; but its precise source is somewhat uncertain. It has been ascribed to the *E. officinarum*, which grows in the North of Africa and at the Cape of Good Hope, the *E. Canariensis*, a native of the Canary Islands and Western Africa, and the *E. antiquorum*, inhabiting Egypt, Arabia, and the East Indies, and supposed to be the plant from which the ancients derived this resinous product. These species of *Euphorbia* bear a considerable resemblance in their general form to the *Cactus*, having leafless, jointed, angular stems, divided into branches of a similar structure, and furnished with double prickles at the angles. When wounded, they give out an acrid milky juice, which concretes upon the surface of the plant, and being removed, constitutes the *euphorbium* of commerce.

This occurs in the shape of tears, or in oblong or roundish masses, about the size of a pea or larger, often forked, and perforated with one or two small conical holes, produced by the prickles of the plant, around which the juice has concreted, and which sometimes remain in the holes. The masses are occasionally large and mixed with impurities. The surface is dull and smooth, bearing some resemblance to that of *tragacanth*; the consistence somewhat friable; the colour light yellowish or reddish; the odour scarcely perceptible; the taste at first slight, but afterwards excessively acrid and burning. The colour of the powder is yellowish. The sp. gr. of *euphorbium* is 1.124. Triturated with water it renders the liquid milky, and is partially dissolved. Alcohol dissolves a larger portion, forming a yellowish tincture, which becomes milky on the addition of water. Its constituents, according to Pelletier, are resin, wax, malate of lime, malate of potassa, lignin, bassorin, volatile oil, and water. Brandes found caoutchouc. *Euphorbium* contains no soluble gum, and is therefore incorrectly called a gum-resin. The proportions of the ingredients are variously stated by different chemists, and probably vary in different specimens. The most abundant is resin, and the remainder consists chiefly of wax and malate of lime. The resin is excessively acrid, is soluble in alcohol, and when exposed to heat, melts, inflames, and burns with a brilliant flame, diffusing an agreeable odour. It is upon this principle that the acrimony of *euphorbium* chiefly depends.

Medical Properties and Uses. *Euphorbium* taken internally is emetic and cathartic, often acting with great violence, and in large doses producing severe gastric pain, excessive heat in the throat, and symptoms of great prostration. In consequence of the severity of its action, its internal use has been entirely abandoned. Applied to the mucous membrane of the nostrils, it excites violent irritation, attended with incessant sneezing, and sometimes bloody discharges. They who powder it are under the necessity of guarding their eyes, nostrils, and mouth against the fine dust which rises. Largely diluted with wheat flour or starch, it may be used as an errhine in amaurosis, deafness, and other obstinate affections of the head. Externally applied, it inflames the skin, often producing vesication; and on

the continent of Europe is sometimes used as an ingredient of epispastic preparations. It is employed in veterinary practice, with a view to its vesicating power. As an article of the *materia medica*, however, it may well be dispensed with, and it has been very properly omitted in the *Pharmacopœia* of the United States.

Off. Prep. Acetum Cartharidis, *Ed.* W.

EXTRACTUM GLYCYRRHIZÆ. *U.S., Lond., Ed., Dub.*

Liquorice.

“The extract of the root of *Glycyrrhiza glabra*.” *U. S.*

Extrait de réglisse, *Fr.*; Süßholzsafft, *Germ.*; Sugo di liquirizia, *Ital.*; Regaliza en bollos, *Span.*

For an account of the *Glycyrrhiza glabra*, see article GLYCYRRHIZA.

The British Colleges direct this extract to be made in the same manner as *Extract of Gentian*; but, as it is never prepared in this country, it very properly occupies, in the United States *Pharmacopœia*, a place in the catalogue of the *Materia Medica*.

Liquorice is an article of export from the North of Spain, particularly Catalonia, where it is obtained in the following manner. The roots of the *G. glabra* having been dug up, thoroughly cleansed, and half dried by exposure to the air, are cut into small pieces, and boiled in water till the liquid is saturated. The decoction is then allowed to rest, and, after the dregs have subsided, is decanted, and evaporated to the proper consistence. The extract thus prepared is formed into rolls from five to six inches long by an inch in diameter, which are dried in the air, and wrapped in laurel leaves.

Much liquorice is also prepared in Calabria, according to M. Fée, from the *G. echinata* which abounds in that country. The process is essentially the same with that just described, but conducted with greater care; and the Italian liquorice is purer and more valuable than the Spanish. We have been informed that most of the extract brought to this country comes from the ports of Leghorn and Messina.

Crude liquorice is in cylindrical rolls, somewhat flattened, and often covered with bay leaves. When good, it is very black, dry, brittle, breaking with a shining fracture, of a very sweet, peculiar, slightly acrid or bitterish taste, and almost entirely soluble in water. It is frequently, however, very impure, either from adulteration or improper preparation. Starch, sand, the juice of prunes, &c., are sometimes added; and carbonaceous matter, and even particles of copper are found in it, the latter arising from the boilers in which the decoction is evaporated. Four pounds of the extract have yielded two drachms and a half of metallic copper. (*Fée.*) It is rarely quite soluble in water. Neumann obtained 460 parts of watery extract from 480 of Spanish liquorice. A bitter and empyreumatic taste are signs of inferior quality. Before being used internally it generally requires to be purified.

The refined liquorice, kept in the shops in small cylindrical pieces not thicker than a pipe stem, is prepared by dissolving the impure extract in water without boiling, straining the solution, and evaporating. The object of this process is to separate not only the insoluble impurities, but also the acrid oily substance, which is extracted by long boiling from the liquorice root, and is necessarily mixed with the unrefined extract. It is customary to add during the process a portion of sugar, and sometimes perhaps mucilage or glue; and flour or starch is a frequent adulteration. Excellent

liquorice is prepared in some parts of England from the root cultivated in that country. The *Pontefract cakes* are small lozenges of liquorice of a very superior quality, made in the vicinity of Pomfret.

Medical Properties and Uses. Liquorice is a useful demulcent, much employed as an addition to cough mixtures, and frequently added to infusions or decoctions, in order to cover the taste or obtund the acrimony of the principal medicine. A piece of it held in the mouth and allowed slowly to dissolve, is often found to allay cough by sheathing the irritated membrane of the fauces. It is used in pharmacy to impart consistence to pills and troches, and to modify the taste of other medicines.

FERRUM.

Iron.

Fer, Fr.; Eisen, Germ.; Ferro, Ital.; Hierro, Span.

Iron is the most abundant and useful of the metals, and so interwoven with the wants of mankind, that the extent of its consumption by a nation may be taken as an index of its progress in civilization. It is universally diffused throughout nature, not only in the mineral kingdom, but also in vegetables and animals. There are very few minerals in which traces of it may not be found, and it is an essential constituent in many parts of animals, but particularly in the blood. It is one of the few metals which are devoid of deleterious action on the animal economy.

Iron occurs, 1. native; 2. sulphuretted, forming magnetic and cubic pyrites; 3. oxidized, embracing the magnetic, specular, red, brown, and argillaceous oxides of iron; 4. in saline combination, forming the carbonate, sulphate, phosphate, arseniate, and chromate of iron. Those minerals of iron which admit of being worked to advantage are called iron ores. These include the different native oxides, and the carbonate (sparry iron.) The best iron is obtained from those varieties of the native oxide, usually called magnetic iron ore and specular iron ore. These occur very abundantly in Sweden, and furnish the superior iron of that country. As a general rule, those ores yield the best iron which occur in primitive formations.

Extraction. The mode of extracting iron from its ores varies somewhat with the nature of the ore; but the general principles of the operation are the same for all. The ore, previously roasted and coarsely pulverized, is exposed to the action of a strong heat in contact with carbonaceous matter, such as charcoal or coke, and in connexion with some flux, capable of fusing with the impurities of the ore. The flux varies with the nature of the ore, and is generally either lime or clay; lime being employed when the ore is argillaceous, clay when it is calcareous. The flux, whatever it may be, enters into fusion with the impurities, and forms what is called the slag; while the carbonaceous matter, acting on the oxide of iron, reduces it to the metallic state. The reduced metal, from its density, occupies the lower part of the furnace, and is protected from the action of the air by the melted slag which floats on its surface. When the reduction is completed, the slag is allowed to run out of a hole in the side of the furnace, and the melted metal, by an aperture at its bottom; the latter being received into oblong triangular moulds, where it solidifies in masses, known in commerce by the name of pig or

cast iron. In this state the metal is brittle and far from being pure; as it is contaminated with a portion of charcoal, unreduced ore, and earthy impurities. It is purified, and thus brought to the state of malleable iron, by being fused, and subjected to the action of a current of air on its surface. By these means the undecomposed ore is reduced, the earthy impurities are made to rise to the surface as a slag, and the carbon is burnt out. As the metal approaches to purity, it becomes less and less fusible, and at last consolidates, though the temperature of the furnace continues the same. The metal is then taken out, and its particles, by means of ponderous hammers, or rollers, are beaten or pressed together so as to form one tenacious mass. It is finally drawn out into bars of a convenient size, when it constitutes the malleable iron of commerce.

Iron mines occur in most countries, but more particularly in northern ones. In Spain the principal mines furnish sparry iron, and the red and brown oxides. The chief iron ores of France are the sparry iron, and the specular, brown, and argillaceous oxides; and of Germany, the sparry iron and brown oxide. The island of Elba is celebrated for its rich and abundant specular oxide. The ores which furnish the celebrated Swedish iron have already been indicated.

In the United States iron is abundant. The principal ores that are worked are the magnetic, brown, and argillaceous oxides. They occur in the greatest abundance in the states of New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, and Pennsylvania. The ores of the three last mentioned states rival the best Swedish in quality.

Properties. Iron is a hard, malleable, very ductile and tenacious metal, of a grayish-white colour and fibrous texture, and having a slight styptic taste, and a sensible odour when rubbed. Its sp. gr. is about 7.7, and its fusing point very high. It possesses the magnetic and welding properties. It is combustible, and when heated to whiteness, burns in atmospheric air, and with brilliant scintillations in oxygen gas. At a red heat, its surface is converted into black oxide, and by the combined agency of air and moisture at common temperatures, it becomes covered with a reddish matter, called *rust*, which consists of the hydrated sesquioxide. It combines with all the non-metallic bodies, except hydrogen and nitrogen, and with most of the metals, its equivalent being 28. It forms three principal combinations with oxygen, a protoxide and sesquioxide, which, by their union, form the black oxide, and a teroxide, possessing acid properties, called ferric acid. The *protoxide* is of a dark-blue colour, attracted by the magnet, and spontaneously combustible in the air, being converted into sesquioxide. It is the base of green vitriol, and of the green salts of iron generally. It is very prone to absorb oxygen, and hence the salts which contain it are soon partially converted, when in solution, into salts of the sesquioxide. It consists of one eq. of iron 28, and one of oxygen 8 = 36. The *sesquioxide* is readily obtained pure by dissolving iron in nitro-muriatic acid, precipitating by ammonia, and igniting the precipitate. It is of a red colour, not attracted by the magnet, and forms salts, which for the most part have a reddish colour. It is composed of two eqs. of iron 56, and three of oxygen 24 = 80. The *black oxide* exists in the native magnetic oxide, and in certain ferruginous salts after they have absorbed a certain definite portion of oxygen. It consists of one eq. of protoxide 36, and one of sesquioxide 80 = 116. The *teroxide* or *ferric acid* has recently been discovered by Frémy, and may be formed, in union with potassa, by passing chlorine through a very concentrated solution of the alkali, holding hydrated sesquioxide of iron in suspension. It has also been obtained by Poggendorff by a galvanic combina-

nation of platinum in nitric acid, with cast iron in a solution of potassa. It forms as a ferrate of potassa, of a fine wine-red colour, becoming darker, around the cast iron. This acid consists of one eq. of iron 28, and three of oxygen 24 = 52. Iron, combined with minute portions of carbon, and, perhaps, of the radicals of silica and alumina, forms *steel*, a modification of iron formerly used in medicine, but now very properly laid aside. It also forms a number of important salts, several of which, as the sesquichloride, iodide, carbonate, subcarbonate, sulphate, phosphate, ferrocyanuret, tartrate, and acetate, are officinal.

Iron is readily detected, even in minute quantities, by bringing it to the state of sesquioxide in solution, and testing it with ferrocyanuret of potassium or tincture of galls; the former of which will strike a deep blue, the latter a black colour. The object of bringing it to the state of sesquioxide is readily effected by boiling the solution containing it with a little nitric acid.

Medical Properties. The preparations of iron are powerfully tonic, raising the pulse, promoting the secretions, and increasing the colouring matter of the blood. They are useful in diseases characterized by debility and relaxation of fibre, and a languid circulation, more especially when the consequence of inordinate discharges. The diseases in which they are most usually employed are chlorosis, hysteria, fluor albus, gleet, scrofula, rickets, chorea, and all passive hemorrhages. Chalybeates are also proper in palsy after the inflammatory excitement has subsided, in dyspepsia dependent upon deficient energy of the digestive functions, and in neuralgia. They are contra-indicated in all inflammatory diseases, producing, when injudiciously prescribed, heat, thirst, headache, difficulty of breathing, and other symptoms of an excited circulation. The medicinal effects of iron, as modified in its different combinations, will be noticed under the head of each preparation.

The following table embraces all the preparations of iron to be found in the United States and British Pharmacopœias, together with the synonymes. Besides these preparations some others will be noticed which are not officinal; viz. *tartrate of protoxide of iron*, under the head of "Ferri et Potassæ Tartras," in Part II.; and *bromide, citrate, ammonio-citrate, lactate, and sesquinitrate of iron*, in the Appendix.

Limailles de Fer, *Fr.*; Eisenfeilicht, *Germ.*; Limatura di ferro, *Ital.*; Limadura de hierro, *Span.*

Iron, when employed in pharmaceutical operations, should be of the purest kind; and hence the different Pharmacopœias direct it, when wanted in small masses, to be in the form of iron wire, which is necessarily made from the softest and most malleable iron, and is readily cut into pieces of convenient size. The metal, however, for internal exhibition and for some preparations, requires to be finely subdivided, and hence it is official also in the form of filings.

Medical Properties of Iron Filings. Iron, in its uncombined state, has no action on the animal economy; and hence iron filings would prove inert, were it not that they meet with acid in the stomach, or some other agent, whereby they become oxidized. That this change really takes place, is

proved by the black stools to which they invariably give rise. During the solution of iron in the stomach, the oxygen furnished to the metal is derived from water, the hydrogen of which, by being disengaged, gives rise to unpleasant eructations. Iron filings are generally obtained from the workshops of the blacksmith; but, as furnished from this source, they are generally very impure, and unfit for medicinal use. Neither can they be purified by the magnet, as they often have attached to them certain impurities, which are carried up with them. The only way to obtain pure iron filings, is to file a piece of pure iron with a clean file. The French Codex directs iron in an impalpable powder, prepared by porphyriizing bright and clean iron filings without water. A dull black powder is formed, which must be carefully preserved from moisture. The dose of iron filings is from five to twenty grains, given in molasses, or made up into an electuary with honey, or into pills with some bitter extract. Upon the whole, there is reason to believe that no medicinal effects can be expected from iron exhibited in the metallic state, which cannot be as well obtained, and with less inconvenience to the patient, from its different combinations.

Iron is used to prepare Potassii Bromidum, *Lond.*, and Potassii Iodidum, *U. S., Lond., Ed.*

FERRUM. Oxydi Squamæ. *Dub.*

Scales of the Oxide of Iron.

Batitures de fer, *Fr.*; Eisenschlag, *Germ.*; Scaglia di ferro, *Ital.*; Escamas de hierro, *Span.*

This form of oxidized iron is obtained when iron is heated to redness and subjected to the blows of a hammer on an anvil. The heat causes the iron to be covered with a thin crust of oxide, which is detached in scales during the hammering. These are formed abundantly in the operations of the blacksmith, and collect around the anvil.

Scales of iron consist of small, black, brittle masses, attracted by the magnet, and without taste or smell. When reduced to powder, they have a dull grayish-white colour. Their precise composition is not well settled; but it is certain that they do not consist of the regular *black oxide*. (See *Ferrum*.) The results of Mosander seem to show that they consist of two distinct layers; the inner, of uniform composition, consisting of six equiv. of protoxide to one of sesquioxide, and the outer, of a variable mixture of these two oxides, the sesquioxide predominating on the surface, and diminishing gradually inwards.

Medical Properties. These scales have the general medical properties of the ferruginous preparations, but are not fit for medicinal use until they have been reduced to fine powder. The Dublin College has given a formula for this purpose, and designates the powdered scales by a distinct name. (See *Ferri Oxydum Nigrum*.) This is the only official preparation of the scales. B.

Gen. Ch. Common receptacle turbinate, fleshy, converging, concealing the florets either in the same or distinct individuals. MALE. *Calyx* three-parted. *Corolla* none. *Stamens* three. FEMALE. *Calyx* five-parted. *Corolla* none. *Pistil* one. *Seed* one, covered with the closed, persistent, somewhat fleshy calyx. *Willd.*

Ficus Carica. Willd. *Sp. Plant.* iv. 1131; Woodv. *Med. Bot.* p. 714. t. 244. The fig-tree, though usually not more than twelve feet in height, sometimes rises in warm climates to twenty-five or even thirty feet. Its trunk, which seldom exceeds seven inches in diameter, is divided into numerous spreading branches, covered with a brown or ash-coloured bark. Its large, palmate leaves, usually divided into five obtuse lobes, are deep green and shining upon their upper surface, pale green and downy beneath, and stand alternately on strong round footstalks. The flowers are situated within a common receptacle, placed solitarily upon a short peduncle in the axils of the upper leaves. This receptacle, the walls of which become thick and fleshy, constitutes what is commonly called the fruit; though this term is, strictly speaking, applicable to the small seeds found in great numbers on the internal surface of the receptacle, to which they are attached by fleshy pedicels. Cultivation has produced in the fig, as in the apple and peach, an almost infinite diversity in shape, size, colour, and taste. It is usually, however, turbinate or top-shaped, umbilicate at the large extremity, of the size of a small pear, of a whitish, yellowish, or reddish colour, and of a mild, mucilaginous, saccharine flavour.

The fig-tree is supposed to have come originally from the Levant. It was introduced at a very early period into various parts of the South of Europe, and is now very common throughout the whole basin of the Mediterranean, particularly in Italy and France. To hasten the maturation of the fruit, it is customary to puncture it with a sharp-pointed instrument covered with olive oil. The ancient process of *caprification* is still practised in the Levant. It consists in attaching branches of the wild fig-tree to the cultivated plant. The fruit of the former contains great numbers of the eggs of an insect of the genus *Cynips*, the larvæ of which, as soon as they are hatched, spread themselves over the cultivated fruit, and by conveying the pollen of the male organs over which they pass to the female florets, hasten the impregnation of the latter, and cause the fig to come quickly to perfection, which might otherwise ripen very slowly, or wither and drop off before maturity. Some authors attribute the effect to the piercing of the fruit by the young insects.

The figs, when perfectly ripe, are dried by the heat of the sun or in ovens. Those brought to the United States come chiefly from Smyrna, packed in drums or boxes. They are more or less compressed, and are usually covered in cold weather with a whitish saccharine efflorescence, which melts in the middle of summer and renders them moist. The best are yellowish or brownish, somewhat translucent when held to the light, and

filled with a sweet viscid pulp, in which are lodged numerous small yellow seeds. They are much more saccharine than the fresh fruit. Their chief constituents are sugar and mucilage.

Medical Properties and Uses. Figs are nutritious, laxative, and demulcent. In the fresh state, they are considered in the countries where they grow a wholesome and agreeable aliment, and have been employed from time immemorial. As we obtain them, they are apt, when eaten freely, to produce flatulence, pain in the bowels, and diarrhœa. Their chief medical use is as a laxative article of diet in cases of constipation. They occasionally enter into demulcent decoctions; and when roasted or boiled, and split open, may be applied as a suppurative cataplasm to parts upon which an ordinary poultice cannot be conveniently retained.

Gen. Ch. *Fructification* in roundish points, scattered, not marginal. *Involute* umbilicated, open almost on every side. *Smith.*

Aspidium Filix mas. Willd. *Sp. Plant.* v. 259; *Smith, Flor. Britan.—Nephrodium Filix mas. Lindley, Flor. Med.* 619.—*Polypodium Filix mas.* Linn.; *Woodv. Med. Bot.* p. 795. t. 267. The male fern has a perennial, horizontal root or rhizoma, from which numerous annual fronds or leaves arise, forming tufts from a foot to four feet in height. The stipe or footstalk, and midrib, are thickly beset with brown, tough, transparent scales, the frond itself is oval lanceolate, acute, pinnate, and of a bright green colour. The pinnæ or leaflets are remote below, approach more nearly as they ascend, and run together at the summit of the leaf. They are deeply divided into lobes, which are of an oval shape, crenate at the edges, and gradually diminish from the base of the pinna to the apex. The fructification is in small dots on the back of each lobe, placed in two rows near the base, and distant from the edges.

The male fern is indigenous, growing in shady pine forests from New Jersey to Virginia. (*Pursh.*) It is a native also of Europe, Asia, and the North of Africa. In the American plant, the leaflets are said by *Pursh* to be more obtuse, and oftener doubly serrated than in the European.

The proper period for collecting the root is during the summer, when, according to *M. Peschier* of Geneva, it abounds more in the active principle than at any other season. The same writer informs us that it deteriorates rapidly when kept, and in about two years becomes entirely inert. The roots of other species of fern are frequently substituted for the officinal; and in the dried state it is difficult to distinguish them.

Properties, &c. As taken from the ground, the root consists of a long cylindrical caudex, around which are closely arranged, overlapping each other like the shingles of a roof, the remains of the leafstalks or stipes,

which are an inch or two in length, from two to four lines thick, somewhat curved and directed upwards, angular, brown, shining, and surrounded near their origin from the root with thin silky scales, of a light brown colour. From between these remains of the footstalks emerge numerous small radical fibres. The whole root, thus constituted, presents a somewhat flexible, cylindrical mass, one or two inches thick, and a foot or more in length. In this form, however, it is not usually found in our shops. The whole is ordinarily broken up into fragments, consisting of the separated remains of the leafstalks before described, with a small portion of the substance of the root attached to their base, where they are surrounded by the silky scales. These fragments ordinarily present the appearance of having been long kept, and are probably, as a general rule, much deteriorated by time. The male fern root is brought to us from Europe, but might perhaps be more advantageously collected in this country. The following observations are made by Geiger in relation to its collection and preservation. The inner parts of the fresh root and of the portions of stalk attached to it, are fleshy and of a light yellowish-green colour. In collecting them, all the black discoloured portions should be cut away, the fibres and scales separated, and only the sound green parts preserved. These should be immediately but carefully dried, and then reduced to powder; and the powder should be kept in small well stopped glass bottles. The powder thus prepared has a pale yellowish colour with a greenish tinge.

Dried fern root is externally of a brown colour, internally yellowish-white or reddish, with a peculiar but feeble odour, which is most obvious in the powder and decoction, and a sweetish, bitter, astringent, nauseous taste. From the analysis of M. Morin, an apothecary of Rouen, it appears to contain a volatile oil, a fixed oil, gallic and acetic acids, uncrystallizable sugar, tannin, starch, a gelatinous matter insoluble in water and alcohol, lignin, and various earthy and saline substances. Geiger found also resin and gum. Peschier ascertained that its active properties reside in the ethereal extract, which is the fixed oil in an impure state, containing volatile oil, resin, colouring matter, &c. It is a thick dark liquid, having the odour of the fern, and a nauseous, bitterish, somewhat acrid taste.

Medical Properties and Uses. Male fern is slightly tonic and astringent; but produces, when taken internally, no very obvious effects upon the system. It was used by the ancients as a vermifuge; and is mentioned in the works of Dioscorides, Theophrastus, Galen, and Pliny. Its anthelmintic powers were also noticed by some of the earlier modern writers, among whom was Hoffmann. But it does not appear to have been generally known to the profession, till attention was attracted to it, about the year 1775, by the publication of the mode of treating tænia employed by Madame Nouffer. This lady, who was the widow of a surgeon in Switzerland, had acquired great celebrity in the cure of tape-worm by a secret remedy. Her success was such as to attract the attention of the medical profession at Paris; and some of the most eminent physicians of that city, who were deputed to examine into the subject, having reported favourably of the remedy, the secret was purchased by the king of France, and published by his order. The outlines of her plan were to give a dose of the powdered root of the male fern, and two hours afterwards a powerful cathartic, to be followed, if it should not operate in due time, by some purging salt; and this process was to be repeated with proper intervals, till the worm should be evacuated. A German physician, of the name of Herrenschwand, had used the male fern in a manner somewhat similar before Madame Nouffer's secret was known. The remedy became very popular for a time, and was found successful in

numerous instances; but the profession has now generally settled down in the opinion that the good which resulted was owing more to the purgatives than to the fern. Instances, however, are recorded, in which cures were effected by the root without the use of cathartics; and amid the general scepticism on the subject, physicians are still found who warmly advocate the anthelmintic powers of the medicine. Dr. Peschier assures us that, in the course of nine months, one hundred and fifty tape-worms had been expelled by the ethereal extract of the male fern root. Dr. Ebers has found the same preparation completely successful in curing eight cases of *tænia*. (*Journ. de Chimie Médicale*, Feb. 1829.) He states that the medicine acts specifically against the worm, which it speedily destroys, and thus favours its expulsion from the body, without producing any severe or unpleasant symptoms. The testimony of Brera is also strongly in favour of the remedy, which he has found effectual even against the armed *tænia*. Perhaps the different results obtained by different practitioners may in part be ascribed to the variable strength and character of the root, dependent upon the season at which it may have been collected, and the length of time it may have been kept. It is also said that the remedy proves more effectual against the tape-worm of the Swiss (*Bothriocephalus latus*) than against the *Tænia solium*, which is more frequent in France and England. (*Bremser*.)

The medicine may be given in powder; or, as recommended by Dr. Peschier, in ethereal extract. The dose of the powder is from one to three drachms, to be given in the form of electuary or emulsion, and repeated morning and evening for one or two days successively. The dose of the ethereal extract (oil of fern) is from twelve to twenty-four grains. The decoction has also been employed in the proportion of an ounce of the root to a pint of water. It is customary to follow the medicine by some brisk cathartic, though Dr. Peschier does not consider this essential. Dr. Mayor of Geneva recommends the oil of fern, in the dose of from thirty to fifty drops, one half to be taken at night, the other half in the morning, and followed at the interval of an hour, by an ounce and a half of castor oil.

FŒNICULUM. U. S., Lond., Ed., Dub.

Fennel-seed.

“The fruit of *Fœniculum vulgare*.” U. S. “*Fœniculum vulgare*. *Fructus*.” Lond. “Fruit of *Fœniculum officinale*.” Ed. “*Anethum Fœniculum*. *Semina*.” Dub.

Fenouil, *Fr.*; Fenchel, *Germ.*; Finocchio, *Ital.*; Hinojo, *Span.*

The plant producing fennel-seed was attached by Linnæus to the genus *Anethum*, but was separated from it by De Candolle, and placed, with three or four others, in a new genus styled *Fœniculum*, which has been generally adopted by botanists. The *Anethum Fœniculum* of Linnæus embraced two varieties, the *common* or *wild fennel*, and the *sweet fennel*, the latter being the plant usually cultivated in the gardens of Europe. These are considered by De Candolle as distinct species, and named respectively *Fœniculum vulgare* and *Fœniculum dulce*. In the U. S. and London Pharmacopœias the former of these is recognised as the source of the medicine; the Edinburgh College adopts the *F. officinale* of Allioni. The latter De Candolle considers as belonging to his *F. vulgare* (see *Prodromus*, iv. 142); while Merat treats of it as a distinct species, differing both from the *F. vulgare* and *F. dulce* of De Candolle (*Dict. de Mat.*

Med.), and Dr. Christison, in his Dispensatory, is disposed to unite it with the last mentioned plant. In this confusion, it is impossible to arrive at any definite and satisfactory conclusion as to the botanical history of the drug under consideration. One thing, however, is certain, that there are two kinds of fennel-seed found in the shops; and it is highly probable that these are derived, if not from distinct species of fennel, at least from marked varieties of the plant. One of them corresponds closely with the description given of the fruit of the *F. vulgare*, while the other is undoubtedly produced by the plant cultivated under the name of sweet fennel, whether that be the *F. dulce* of De Candolle, or *F. officinale* of Allioni and Merat.

FœNICULUM. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferae or Apiaceæ.

Gen. Ch. *Calyx* a tumid obsolete rim. *Petals* roundish, entire, involute, with a squarish blunt lobe. *Fruit* nearly taper. *Half-fruits* with five prominent bluntly keeled ridges, of which the lateral are on the edge, and rather broadest. *Vittæ* single in the channels, two on the commissure. *Involucre* none. (*Lindley.*)

Fœniculum vulgare. De Cand. *Prodrom.* iv. 142.—*Anethum Fœniculum.* Linn.; Woodv. *Med. Bot.* p. 127. t. 49. *Common fennel* has a biennial or perennial tapering root, and an annual, erect, round, striated, smooth, green, and copiously branching stem, which usually rises three or four feet in height. The leaves, which stand alternately at the joints of the stem, upon membranous striated sheaths, are many times pinnate, with long, linear, pointed, smooth, deep green leaflets. The flowers are in large, flat, terminal umbels, with from thirteen to twenty rays, and destitute both of general and partial involucre. The corolla consists of five petals, which, as well as the stamens, are of a golden yellow colour. The fruit is ovate, rather less than two lines in length by about a line in breadth, and of a dark colour, especially in the channels. The plant is a native of Europe, growing wild upon sandy and chalky ground throughout the continent.

F. officinale. Merat and De Lens, *Dict. de Mat. Med.* iii. 270; *Ed. Pharm.*; Allioni. This, which is sometimes called *sweet fennel*, is also perennial, with shorter leaves and less elongated leaflets than the common fennel, but resembling it very closely except in the character of the fruit. This is twice as long as that of the former plant, a little curved, of a less dark colour, with prominent ridges, and a persistent peduncle. It is more aromatic and sweeter than common fennel-seed. The plant is a native of the South of Europe; but is cultivated elsewhere in gardens, and is probably the source of much of the fennel-seed of the shops. Whether it is a distinct species, or a mere variety of the *F. vulgare*, is not determined. Some confound it with the following.

F. dulce. De Cand. *Prodrom.* iv. 142. This plant is eminently entitled to the name of *sweet fennel*. It bears a general resemblance to the *F. vulgare*, but differs in having its stem somewhat compressed at the base, its radical leaves somewhat distichous, and the number of rays in the umbel only from six to eight. It is also a much smaller plant, being only about a foot in height, its flowers appear earlier, and its young shoots or turiones are sweeter and edible. It is a native of Portugal, Italy, and perhaps other parts of Southern Europe; and is cultivated largely in Italy and Sicily for the sake of the shoots, which are eaten raw, or in salad, or boiled as pot herbs. The fruit is described by Merat and De Lens as “being globular-ovate, twice the size of that of common fennel, and with prominent ridges. This description does not answer to the character of any of the fennel-seed we have seen in the shops.

In all these species or varieties, the whole plant has an aromatic odour and taste, dependent on a volatile oil by which it is pervaded. The roots were formerly employed in medicine, but are greatly inferior in virtues to the fruit, which is now the only official portion. Our shops are partly supplied from our own gardens, but much the larger portion of the medicine is imported from Europe, and chiefly, as we have been informed, from Germany. The fennel-seed cultivated here is sweeter and more aromatic than that from abroad, probably in consequence of its greater freshness.

Fennel seeds (half-fruits) are oblong oval, from one to three or four lines in length, flat on one side, convex on the other, not unfrequently connected by their flat surfaces, straight or slightly curved, of a dark grayish-green colour, with longitudinal yellowish ridges on the convex surface. There are two varieties, one of them from one to two lines long, dark-coloured, rather flat, almost always separate, and without footstalks; the other three or four lines, sometimes even five lines in length, lighter-coloured, with much more prominent ridges, often conjoined by their flat surface, and very frequently provided with a footstalk. They do not differ essentially in aromatic properties. The odour of fennel-seed is fragrant, its taste warm, sweet, and agreeably aromatic. It imparts its virtues to hot water, but more abundantly to alcohol. The essential oil may be separated by distillation with water. (See *Oleum Fœniculi*.) The seeds contain also fixed oil. From 960 parts of them, Neumann obtained 20 parts of the former, and 120 of the latter.

Medical Properties and Uses. Fennel-seed was used by the ancients, is among our most grateful aromatics, and in this country is much employed as a carminative, and as a corrigent of other less pleasant medicines, particularly senna and rhubarb. It is recommended for these purposes by the absence of any very highly excitant property. The infusion, prepared by introducing two or three drachms of the seeds into a pint of boiling water, is the form usually preferred. The dose of the bruised or powdered seeds is from a scruple to half a drachm. In infantile cases, the infusion is frequently employed as an enema to produce the expulsion of flatus.

FRASERA. U. S. Secondary.

American Columbo.

“The root of *Frasera Walteri*.” *U. S.*

FRASERA. *Sex. Syst.* Tetrandria Monogynia.—*Nat. Ord.* Gentianaceæ.

Gen. Ch. Calyx deeply four-parted. Corolla four-parted, spreading; segments oval, with a bearded, orbicular gland in the middle of each. Capsule compressed, partly marginated, one-celled. Seeds few, imbricated, large, elliptical, with a membranaceous margin. *Nuttall.*

Frasera Walteri. Michaux, *Flor. Bor. Americ.* i. 96; Barton, *Med. Bot.* ii. 103.—*F. Carolinensis.* Walter. This is one of our most elegant indigenous plants, and the only one of its genus hitherto discovered. From the root, which is triennial, long, spindle-shaped, horizontal, fleshy, and of a yellow colour, a strong, succulent, solid, smooth stem rises, from five to ten feet in height. The leaves are sessile, entire, glabrous, of a deep-green colour, and disposed in whorls, which commence at the root, and ascend to the summit

with successively diminishing intervals. The radical leaves, from five to twelve in number, are elliptical, obtuse, a foot or more in length by about four inches in breadth, and lie upon the ground in the form of a star. Those constituting the whorls upon the stem are successively smaller as they ascend—the lowest oblong lanceolate, the upper lanceolate and pointed. The flowers are numerous, large, of a yellowish-white colour, and disposed in a beautiful terminal pyramidal panicle, from one to five feet long, the branches of which spring from the axils of the upper leaves. The segments of the calyx are lanceolate, acute, and somewhat shorter than those of the corolla. The filaments are inserted into the base of the corolla, between its segments, which they do not equal in length. The anthers are oblong and notched at the base. The germ is oblong ovate, compressed, and gradually tapers into the style, which terminates in a bifid stigma. The fruit is an oval, acuminate, compressed, two-valved, one-celled, yellow capsule, containing from eight to twelve flat, elliptical seeds.

The *Frasera* flourishes in the southern and western portions of the United States, and in many situations is very abundant, especially in Arkansas and Missouri. It prefers rich woodlands and moist meadows. The period of flowering is from May to July; but the stem and flowers are produced only in the third year, the radical leaves being the only part of the plant which previously appears above ground. From this manner of growth it is inferred, that the root should be collected in the autumn of the second or the spring of the third year. Before being dried, it should be cut into transverse slices.

As formerly found in the market, *Frasera* was in pieces irregularly circular, an eighth of an inch or more in thickness, about an inch in diameter, somewhat shrunk in the middle, consisting of a central medullary matter and an exterior cortical portion, of a yellowish colour on the cut surfaces, with a light reddish-brown epidermis. In appearance these pieces bore some resemblance to columbo, but were easily distinguishable by the greater uniformity of their internal structure, the absence of concentric and radiating lines, and their purer yellow colour without a greenish tinge. The taste of *Frasera* is bitter and sweetish. Water and diluted alcohol extract its virtues, and the tincture throws down a precipitate upon the addition of water, but is not disturbed by tincture of galls; thus affording additional means of distinguishing the root from columbo.

Medical Properties and Uses. *Frasera* is a mild tonic, calculated to meet the same indications with the other simple bitters. It has been thought to resemble columbo in medical properties as well as in appearance, and hence has received the popular name of *American columbo*; but experience has not confirmed the high estimate which was at one time formed of its virtues; and though, perhaps, still occasionally employed in some parts of the country, it has failed to supplant the tonic of Mozambique. It may be given in powder or infusion. The dose of the former is from thirty grains to a drachm, that of an infusion, made in the proportion of an ounce of the bruised root to a pint of boiling water, is one or two fluidounces, to be repeated several times a day.

The fresh root is said to operate as an emetic and cathartic, and has sometimes been given with a view to the latter effect.

W.

GALBANUM. *U.S., Lond., Ed., Dub.**Galbanum.*

“The concrete juice of an unknown plant.” *U.S.* “Galbanum officinale. *Gummi-resina.*” *Lond.* “Concrete gummy-resinous juice of an imperfectly ascertained umbelliferous plant, probably a species of *Opoidia.*” *Ed.* “Bubon Galbanum. *Gummi-resina.*” *Dub.*

Galbanum, *Fr.*; Mutterharz, *Germ.*; Galbano, *Ital., Span.*

It is not certainly known from what plant galbanum is derived. At one time it was supposed to be the product of the *Bubon Galbanum*, an umbelliferous plant, growing on the eastern coast of Africa from Nubia to the Cape of Good Hope;—and this is still recognised as the source of it by the Dublin College. It has also been referred to the *Ferula ferulago* of Linnaeus, the *Ferula galbanifera* of Lobel, which inhabits the coasts of the Mediterranean, and is found also in Transylvania and the Caucasus. But no part of either of these plants possesses the odour of galbanum; and it is, therefore, scarcely probable that they yield the drug. Mr. Don, having found the seeds taken from a parcel of galbanum to belong to an undescribed genus of umbelliferous plants, and concluding that they came from the same source as the gum-resin itself, gave the title of Galbanum to the new genus, and named the species *Galbanum officinale*. This has been rather hastily adopted by the London College; as it is by no means certain, however probable it may be, that the same plant produced the seeds and the gum-resin. Specimens of a plant were recently sent to England by Sir John McNeill, collected in 1838 near Durrood, in the Persian province of Chorassan. The plant was supposed to yield a variety of ammoniac, and portions of a pale yellow gum-resin were adhering to the specimens received. Dr. Lindley ascertained that the plant belonged to an undescribed genus, which he named *Opoidia*, and, under the impression that the adhering concrete juice was identical with galbanum, designated the particular species *O. galbanifera*. Dr. Pereira, however, found the substance to be unlike galbanum or any other product of the Umbelliferae. This supposed origin of the drug, therefore, though admitted as probable by the Edinburgh College, must be considered as more than doubtful. In this state of uncertainty, it is scarcely necessary to describe particularly any one of the plants referred to.

Galbanum is said to be obtained from the plant by making incisions into the stem, or cutting it off a short distance above the root. A cream-coloured juice exudes, which concretes upon exposure to the air. A small portion of juice also exudes spontaneously from the joints, and hardens in the shape of tears. The drug is brought from the Levant, and, according to Lindley, also from India.

Properties. The form in which galbanum usually appears is that of masses, composed of whitish, reddish, or yellowish tears, irregularly agglutinated by a darker coloured yellowish-brown, or greenish substance, more or less translucent, and generally mixed with pieces of stalk, seeds, or other foreign matters. It is also found, though very rarely, if at all, in our markets, in the state of distinct, roundish tears, about as large as a pea, of a yellowish-white or pale brownish-yellow colour, shining externally as if varnished, and often adhering together. Galbanum has in cool weather the consistence of firm wax; but softens in summer, and by the heat of the

hand is rendered ductile and adhesive. At the temperature of boiling water it is sufficiently liquid to admit of being strained; and generally requires to be strained before it can be used. A dark brown or blackish colour, a consistence always soft, the absence of whitish grains, and the intermixture of earthy impurities, are signs of inferiority.

The odour of galbanum is peculiar and disagreeable, but not alliaceous like that of sagapenum. Its taste is bitterish, warm, and acrid. Its specific gravity is 1.212. When triturated with water it forms an imperfect milky solution, which upon standing deposits the greater portion of what was taken up. Wine and vinegar act upon it in a similar manner. Alcohol dissolves a considerable proportion, forming a yellow tincture, which has the smell and taste of galbanum, and becomes milky by the addition of water, but affords no precipitate. In dilute alcohol it is wholly soluble, with the exception of impurities. One hundred parts of it yielded to Pelletier 66.86 parts of resin, 19.28 of gum, 6.34 of volatile oil including the loss, 7.52 of wood and impurities, with traces of the supermalate of lime. A small proportion of bassorin was also found by Meissner. The medicine is, therefore, entitled to rank with the *gum-resins*. By distillation at the temperature of about 250° F., the essential oil is obtained of a fine indigo blue colour, which it imparts to alcohol. Procured by distillation with water, it is colourless, and becomes yellowish by age. It is lighter than water.

According to Ludewig, a gum-resin, designated as *Persian galbanum*, is received in Russia by the way of Astracan and Orenburg, and is the kind used in that country. It comes enclosed in skins, and is in masses of a reddish-brown colour with whitish streaks, of a disagreeable odour somewhat like that of assafetida, and of an unpleasant, bitter, resinous taste. It is so soft as to melt with a slight elevation of temperature. It differs from common galbanum in its odour, in its colour which is never greenish, and in the absence of tears, and is probably derived from a different plant. It abounds in impurities. (*Journ. de Pharm. N. S.* i. 117.)

Medical Properties and Uses. Galbanum is stimulant, expectorant, and antispasmodic; and may be considered as intermediate in power between ammoniac and assafetida. It is, however, much less employed than either of these gum-resins, and in the United States is seldom or never prescribed internally. The complaints to which it was formerly thought applicable, were chiefly chronic affections of the bronchial mucous membrane, amenorrhœa, and chronic rheumatism. It is occasionally applied externally in the shape of plaster to indolent swellings, with the view of promoting resolution or suppuration. Galbanum was known to the ancients. The dose is from ten to twenty grains, and may be given in pill, or triturated with gum Arabic, sugar, and water, so as to form an emulsion.

GALLA. U.S.

Galls.

“Morbid excrescences upon *Quercus infectoria*.” *U. S.*

Off. Syn. GALLÆ. *Quercus infectoria*. *Gemmæ morbidæ*. *Lond.* GALLÆ. Excrescences of *Quercus infectoria*, formed by *Diplolepis Gallæ tinctorum*. *Ed.*; GALLÆ. QUERCUS INFECTORIA. *Dub.*

Noix de galle, *Fr.*; Galläpfel, *Germ.*; Galla, *Ital.*; Agallas de Levante, *Span.*

Many vegetables when pierced by certain insects, particularly those of the genus *Cynips*, are affected at the points of puncture with a morbid action, resulting in the production of excrescences, which, as they are derived from the proper juices of the plant, partake more or less of its predominant chemical character. Most species of oak are susceptible of this kind of action; and the resulting excrescences, having in a high degree the astringency of the plant on which they grow, have been employed for various practical purposes. They are known by the name of *galls*, a term which, as well as their employment in medicine, has been handed down to us from the ancients. The *Quercus infectoria*, *Q. Ægilops*, *Q. excelsa*, *Q. Ilex*, *Q. Cerris*, and *Q. Robur*, have all been particularized as occasionally affording this product; but it is now generally admitted, upon the authority of Olivier, that the officinal galls are derived chiefly, if not exclusively, from the *Q. infectoria*, and this is recognised as their source in the Pharmacopœias of the United States and Great Britain.

QUERCUS. See QUERCUS ALBA.

Quercus infectoria. Willd. *Sp. Plant.* iv. 436; Olivier, *Voy. Or.* t. 14 et 15. The *dyers' oak* is a small tree or shrub, with a crooked stem, seldom exceeding six feet in height. The leaves are obtusely toothed, smooth, of a bright green colour on both sides, and stand on short footstalks. The acorn is elongated, smooth, two or three times longer than the cup, which is sessile, somewhat downy, and scaly. This species of *Quercus* grows, according to Olivier, throughout Asia Minor, from the Archipelago to the confines of Persia. Captain M. Kinneir found it also in Armenia and Kurdistan; General Hardwicke observed it growing in the neighbourhood of Adwanie; and it probably pervades the middle latitudes of Asia.

The gall originates from the puncture of the *Cynips quercusfolii* of Linnaeus, the *Diplolepis Gallæ tinctoriæ* of Geoffroy, a hymenopterous insect or fly, with a fawn-coloured body, dark antennæ, and upper part of its abdomen shining brown. The insect pierces the shoots and young boughs, and deposits its egg in the wound. This irritates the vessels of the part, and a small tumour very speedily rises, which appears to be the result of a morbid secretion, and upon examination by the microscope exhibits no signs of proper vegetable fibre. The egg grows with the gall, and is soon converted into a larva, which feeds upon the vegetable matter by which it is surrounded, and thus forms a cavity in the centre of the tumour. The insect at length assumes the form of a fly, and escapes by eating its way out of the excrescence. The galls are in perfection when they have attained their full size, and before the egg has been hatched, or the fly has escaped. Collected at this period, they are called, from their dark colour, *blue*, or *green*, or *black galls*, and are most highly esteemed. Those which are gathered later, and which have been injured by the insect, are called *white galls*. They are usually larger, less heavy and compact, and of a lighter colour than the former; and are considered much inferior.

The galls collected in Syria and Asia Minor are brought to this country chiefly from the ports of Smyrna and Trieste. As they are produced abundantly in the vicinity of Aleppo, it has been customary to designate them by the name of that city; though the designation, however correct it may formerly have been, is now wholly inapplicable, as they are obtained from many other places, and the produce of different parts of Asiatic Turkey is not capable of being discriminated, at least in our markets. Great quantities of galls very closely resembling those from the Mediterranean have been brought to the United States from Calcutta. Whether they are the produce of Hindostan, or taken thither from other countries, we are unable to decide with certainty. Ainslie is inclined to think that most of the galls found in the markets of India are imported from Persia by the Arab merchants. We are, nevertheless, informed that they are among the products of Moultan. The galls of France and other southern countries of Europe have a smooth, shining, reddish surface, are little esteemed, and are seldom or never brought to the United States.

Properties. Galls are nearly round, from the size of a pea to that of a very large cherry, with a surface usually studded with small tuberosities, in the intervals of which it is smooth. The best are externally of a dark bluish or lead colour, sometimes with a greenish tinge, internally whitish or brownish, hard, solid, brittle, with a flinty fracture, a striated texture, and a small spot or cavity in the centre, indicating the presence of the undeveloped or decayed insect. Their powder is of a light yellowish-gray. Those of an inferior quality are of a lighter colour, sometimes reddish or nearly white, of a loose texture, with a large cavity in the centre, communicating externally by a small hole through which the fly has escaped. Galls are inodorous, and have a bitter very astringent taste. From 500 parts Sir H. Davy obtained 185 parts of matter soluble in water, of which, according to his analysis, 130 were tannin, 31 gallic acid with a little extractive, 12 mucilage and matter rendered insoluble by evaporation, and 12 saline matter and calcareous earth. Other chemists have found a larger proportion of tannin and gallic acid. Braconnot discovered the presence of a small quantity of another acid, to which he gave the name *ellagic*, derived from *galle*, the French name for galls, by reversing the order of the letters. According to M. Pelouse, however, neither gallic nor ellagic acid pre-exists in galls, being formed by the reaction of atmospheric oxygen upon their tannin. (*Journ. de Pharm.* xx. 359.) Galls also yielded to Professor Branchi, by distillation with water, a concrete volatile oil. All their soluble matter is taken up by forty times their weight of boiling water, and the residue is tasteless: alcohol dissolves seven parts in ten, ether five parts. (*Thomson's Dispensatory.*) A saturated decoction of galls deposits upon cooling a copious pale-yellow precipitate. The infusion or tincture affords precipitates with sulphuric and muriatic acids, lime-water, carbonate of ammonia, and carbonate of potassa; with solutions of acetate and subacetate of lead, the sulphates of copper and iron, the nitrates of silver and mercury, and tartrate of antimony and potassa; with the infusions of Peruvian bark, columbo, opium, and many other vegetables, especially those containing proximate alkaline principles, with most of which tannin forms insoluble compounds. The solution of gelatin also produces a precipitate. The infusion of galls reddens litmus paper, is rendered orange by nitric acid, milky by the corrosive chloride of mercury, and has its own colour deepened by ammonia; but throws down no precipitate with either of these reagents. Sulphate of zinc is said by Dr. A. T. Thomson to occasion a slow precipitate, but this result was not obtained by Dr. Duncan.

Medical Properties and Uses. As might be inferred from the quantity of tannin they contain, galls are powerfully astringent. They are little employed as an internal remedy, though occasionally prescribed in chronic diarrhœa. They have been recommended as an antidote to tartar emetic, and those vegetable poisons which depend for their activity upon organic alkalies; but, though the insoluble compounds which these principles form with galls are probably less active than their soluble native compounds, they cannot be considered as inert. In the form of infusion or decoction, galls may be advantageously used as an astringent gargle, lotion, or injection; and, mixed with simple ointment, in the proportion of one part of galls, in very fine powder, to eight parts of the unguent, they are frequently applied to the anus and rectum in hemorrhoidal affections. The dose of powdered galls is from ten to twenty grains, to be repeated several times a day.

GAMBOGIA. *U. S.*

Gamboge.

“The concrete juice of an uncertain tree.” *U. S.*

Off. Syn. CAMBOGIA. *Stalagmitis Cambogioides. Gummi-resina. Lond.*; CAMBOGIA (*SIAMENSIS*). Gum-resin from an unascertained plant inhabiting Siam, probably a species of *Hebradendron*. CAMBOGIA (*ZEYLANICA*). Gummy-resinous exudation of *Hebradendron cambogioides. Ed.*; GAMBOGIA. *STALAGMITIS CAMBOGIA. Dub.*

Gomme gutte, Fr.; Gummigutt, Germ.; Gomma-gotta, Ital.; Gotta gamba, Span.

Several plants belonging to the natural family of the *Guttiferæ*, growing in the equatorial regions, yield on incision a yellow opaque juice, which hardens on exposure to the air, and bears a close resemblance to gamboge; but it is not certainly known from which of these plants the officinal gum-resin is procured. Until recently, the United States and all the British Pharmacopœias ascribed it to the *Stalagmitis Cambogioides*. This genus and species were established by Murray of Göttingen, in 1788, from dried specimens belonging to König, procured in the island of Ceylon; and from information derived from the same source, it was conjectured by Murray that the tree yielded not only the gamboge of Ceylon, but that also collected in Siam. It was on this authority that the British Colleges made the reference alluded to. But it has been ascertained by Dr. Graham, of Edinburgh, that there is no such plant as the *Stalagmitis Cambogioides*; the description of Murray having been drawn up from accidentally conjoined specimens of two distinct trees belonging to different genera. By several botanists the gum-resin has been ascribed to the *Garcinia Cambogia*, also a tree of Ceylon belonging to the family of *Guttiferæ*, and yielding a yellowish, concrete juice; but a specimen of the product of this tree sent to Edinburgh was found by Dr. Christison to be different from gamboge both in composition and appearance, being of a pale lemon-yellow colour. Thus it appears that neither of these references is correct; and besides, the important fact seems to have been overlooked, that commercial gamboge is never obtained from Ceylon, but exclusively from Siam and Cochin-china. It is true that a gum-resin from Ceylon has recently been examined, and found similar in composition to the gamboge of commerce; that the tree which produced it, having been ascertained by Dr.

Graham to belong to a new genus, has been named by him *Hebradendron Cambogioides*, and is one of the two confounded by Murray in his *Stalagmitis*; and that the Edinburgh College, in the last edition of their *Pharmacopœia*, has adopted this Ceylon gamboge as officinal. But, as this variety is never found in commerce, and exists only in the cabinets of the curious, it scarcely seems worthy of a place in an officinal catalogue; and though, from its resemblance to the Siam gum-resin, the two may possibly be derived from the same or closely analogous plants, yet the fact is not proved; and it would be altogether premature at present to ascribe the latter to this or any other species of *Hebradendron*.

On the whole, therefore, it must be admitted that we are uncertain, not only as to the precise tree which affords the officinal gamboge, but also whether it is derived from any one tree exclusively, or from several. In this uncertainty, it seems hardly necessary to crowd our pages with botanical descriptions, which may possibly have no relation to the subject.

Gamboge is collected in Siam and Cochin-china. Similar products are obtained in Ceylon; but they do not appear to be sent out of the island. Milburn does not mention gamboge among the exports. The tree from which it is obtained in Siam has not been examined by any botanist. It is said to be procured by breaking off the leaves and young shoots, from which the juice issues in drops, and being received in suitable vessels gradually thickens, and at length becomes solid. When it has attained the requisite consistence, it is rolled into cylinders, and wrapped in leaves. The juice is sometimes received into the hollow joints of the bamboo, which give it a cylindrical form; and, as it contracts during the process of solidification, the cylinder is often hollow in the centre. The name *gummi gutta*, by which it is generally known on the continent of Europe, probably originated from the circumstance that the juice escapes from the plant by drops. The officinal title was undoubtedly derived from the province of Cambodia, in which the gum-resin is collected. It was first brought to Europe by the Dutch about the middle of the seventeenth century.

We import gamboge from Canton and Calcutta, whither it is carried by the native or resident merchants. There is no difference in the appearance or character of the drug as brought from these two ports—an evidence that it is originally derived from the same place.

Varieties. The best gamboge is in cylindrical rolls, from one to three inches in diameter, sometimes hollow in the centre, sometimes flattened, often folded double, or agglutinated in masses in which the original form is not always readily distinguishable. The pieces sometimes appear as if rolled, but are in general striated longitudinally from the impression made by the inner surface of the bamboo. They are externally of a dull orange colour, which is occasionally displaced by greenish stains, or concealed by the bright yellow powder of the drug, which slightly adheres to the surface. In this form the drug is sometimes called *pipe gamboge*. Another variety is imported under the name of *cake* or *lump gamboge*. It is in irregular masses weighing two or three pounds or more, often mixed with sticks and other impurities, containing many air-cells, less dense, less uniform in texture, and less brittle, than the former variety, and breaking with a dull and splintery, instead of a shining and conchoidal fracture. The worst specimens of this variety, as well as of the cylindrical, are sometimes called by the London druggists *coarse gamboge*. They differ, however, from the preceding, only in containing a greater amount of impurities. Indeed, it would appear, from the experiments of Christison, that all the commercial varieties of this drug have a common origin, and that cake or lump gamboge

differs from that which comes in the cylindrical form, only from the circumstance that the latter is the pure concrete juice of the plant, while, in the former, farinaceous matter and other impurities have been mixed with the pure juice for the purpose of adulteration. The inferior kinds of gamboge may be known by their greater hardness and coarser fracture; the brownish or grayish colour of their broken surface, which is often marked with black spots; by their obvious impurities; and by the green colour which their decoction, after having been cooled, gives with tincture of iodine. When pure, the gum-resin is completely dissolved by the successive action of ether and water.*

Properties. Gamboge, in its pure form, is brittle, with a smooth, conchoidal, shining fracture; and the fragments are slightly translucent at their edges. The colour of the mass when broken is a uniform reddish-orange, which becomes a beautiful bright yellow in the powder, or when the surface is rubbed with water. From the brilliancy of its colour, gamboge is highly esteemed as a pigment. It has no smell, and little taste; but after remaining a short time in the mouth produces an acrid sensation in the fauces. Its sp. gr. is 1.221. Exposed to heat it burns with a white flame, emitting much smoke, and leaving a light spongy charcoal. It is a gum-resin, and, unlike most other substances of the same class, contains no essential oil. In 100 parts of it Braconnot found 19.5 parts of gum, 0.5 of impurities, and 80 of a red, insipid, transparent resinous substance, becoming yellow by pulverization, and supposed to consist of resin united with a yellow colouring principle. John obtained 10.5 per cent. of gum, 89 of resin, and 0.5 of impurities. Christison has shown that the proportion of gum and resin varies in different specimens even of the purest drug. His results approach nearly to those of Braconnot. In one experiment, out of 100.8 parts he obtained 74.2 of resin, 21.8 of gum, and 4.8 of water. The gum is quite soluble in water and of the variety denominated arabin. In a specimen of *cake gamboge* he found 11.2 per cent. of fecula and lignin, and in a very bad sample of *coarse gamboge*, no less than 41 per cent. of the same impurities. (*Am. Journ. of Pharm.* ix. 133.) Gamboge is readily and entirely diffusible in water, forming a yellow opaque emulsion, from which the resinous matter is very slowly deposited. It is dissolved by alcohol, with the exception of about 8 or 10 per cent. of gum; and a golden yellow tincture results, which is rendered opaque and bright yellow by the addition of water. Its solution in ammoniated alcohol is not disturbed by water. Sulphuric ether dissolves about four-fifths of it, taking up only the resin, which is obtained by the evaporation of the ethereal solution. It is wholly taken up by alkaline solutions, from which it is partially precipitated by the acids. The strong acids dissolve it; but the solution when diluted with water deposits a yellow precipitate. The colour as well as the acrimony and medicinal power of gamboge reside in the resinous portion; but, as pure resins are usually destitute of these properties, it is not improbable that they may belong to a distinct principle not yet separated from the

* *Ceylon gamboge*, derived from the *Hebradendron Cambogioides* of Graham (*Cambogia gutta*, Linn., *Garcinia Morella*, De Cand.) is procured by incisions, or by cutting away a portion of the bark, and scraping off the juice which exudes. The specimens sent to Dr. Christison are in flattish or round masses, eight or nine inches in diameter, apparently composed of aggregated irregular tears, with cavities which are lined with a grayish and brownish powdery incrustation. Its general aspect is that of coarse gamboge, but the individual tears have the characters of the best kind, and its chemical composition is identical. It is used as a pigment and purgative in Ceylon, but is not an article of commerce. (*Christison's Dispensatory*.)

resin. So intense is the colour of the resin that one part of it communicated a perceptible yellowness to ten thousand parts of water or spirit. It has the acid property of combining with salifiable bases, and hence has been called *gambogic acid*.

Medical Properties and Uses. Gamboge is a powerful, drastic, hydragogue cathartic, very apt to produce nausea and vomiting when given in the full dose. In large quantities it is capable of producing fatal effects, and death has resulted from a drachm. It is much employed in the treatment of dropsy attended with torpid bowels, generally in combination with the bitartrate of potassa or jalap. It is also prescribed in cases of obstinate constipation, and has frequently been found effectual in the expulsion of the tapeworm. It is often combined with other and milder cathartics, the action of which it promotes and accelerates, while its own is moderated. The full dose is from two to six grains, which in cases of tænia has been raised to ten or fifteen grains. As it is apt to occasion much sickness and griping, the best plan, under ordinary circumstances, is to give it in small doses repeated at short intervals till it operates. It may be given in pill or emulsion, or dissolved in an alkaline solution. The last method of administration has been recommended in dropsical complaints.

GAULTHERIA. U. S.

Partridge-berry.

"The leaves of *Gaultheria procumbens*." U. S.

GAULTHERIA. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Ericaceæ.

Gen. Ch. Calyx five-cleft, bibracteate at the base. Corolla ovate. Capsule five-celled, invested with the berried calyx. *Pursh.*

Gaultheria procumbens. Willd. *Sp. Plant.* ii. 616; Bigelow, *Am. Med. Bot.* ii. 27; Barton, *Med. Bot.* i. 171. This is a small, indigenous, shrubby, evergreen plant, with a long, creeping horizontal root, which sends up at intervals one and sometimes two erect, slender, round, reddish stems. These are naked below, leafy at the summit, and usually less than a span in height. The leaves are ovate or obovate, acute, revolute at the edges with a few mucronate serratures, coriaceous, shining, bright green upon the upper surface, paler beneath, of unequal size, and supported irregularly on short red petioles. The flowers, of which not more than from three to five are usually found upon each stem, stand on curved, drooping, axillary peduncles. The calyx is white, five-toothed, and furnished at its base with two concave cordate bractes, which are by some authors described as an outer calyx. The corolla is white, ovate or urceolate, contracted at its mouth, and divided at its border into five small acute segments. The stamens consist of curved, plumose filaments, and oblong orange-coloured anthers, opening on the outside. The germ, which rests upon a ring having ten teeth alternating with the ten stamens, is roundish, depressed, and surmounted by an erect filiform style, terminating in an obtuse stigma. The fruit is a small, five-celled, many-seeded capsule, enclosed in a fleshy covering, formed by the enlarged calyx, and presenting the appearance of a bright scarlet berry.

The plant extends from Canada to Georgia, growing in large beds in mountainous tracts, or in dry barrens and sandy plains, beneath the shade of shrubs and trees, particularly of other evergreens, as the *Kalmiæ* and *Rho-*

hodendra. It is abundant in the pine barrens of New Jersey. In different parts of the country, it is known by the various names of *partridge-berry*, *deer-berry*, *tea-berry*, *winter-green*, and *mountain-tea*. The flowers appear from May to September, and the fruit ripens at corresponding periods. Though the leaves only are officinal, all parts of the plant are endowed with the peculiar flavour for which these are employed, and which is found in several other plants, particularly in the bark of the *Betula lenta*, or sweet birch. The fruit possesses it in a high degree, and, being at the same time sweetish, is much relished by some persons, and forms a favourite article of food with partridges, deer, and other wild animals.

To the very peculiar and agreeably aromatic odour and taste which belong to the whole plant, the leaves add a marked astringency, dependent on the presence of tannin. The aromatic properties reside in a volatile oil, which may be separated by distillation. (See *Oleum Gaultheriæ*.)

Medical Properties and Uses. Gaultheria has the usual stimulant operation of the aromatics, united with astringency; and may, therefore, be used with advantage in some forms of chronic diarrhœa. Like other substances of the same class, it has been employed as an emmenagogue, and with the view of increasing the secretion of milk; but its chief use is to impart an agreeable flavour to mixtures and other preparations. It may be conveniently administered in the form of infusion, which in some parts of the country is not unfrequently used at the table as a substitute for common tea. The oil, however, is more used in regular practice than the leaves. Instances of death are on record, resulting from the use of the oil, by mistake, in the quantity of about a fluidounce. On examination after death, strong marks of inflammation of the stomach were discovered. (*Journ. of Phil. Col. of Pharm.*, vi. 290.)

Gentiane jaune, *Fr.*; Rother Enzian, *Germ.*; Genziana, *Ital.*; Genciana, *Span.*

GENTIANA. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Gentianaceæ.

Gen. Ch. Corolla one-petalled. Capsule two-valved, one-celled, with two longitudinal receptacles. Willd.

Gentiana lutea. Willd. *Sp. Plant.* i. 1331; Woodv. *Med. Bot.* p. 273. t. 95. Yellow gentian is among the most remarkable of the species which compose this genus both for its beauty and great comparative size. From its thick, long, branching, perennial root, an erect, round stem rises to the height of three or four feet, bearing opposite, sessile, oval, acute, five-nerved leaves, of a bright-green colour, and somewhat glaucous. The lower leaves, which spring from the root, are narrowed at their base into the form of a petiole. The flowers are large and beautiful, of a yellow colour, peduncled, and placed in whorls at the axils of the upper leaves. The calyx is monophyllous, membranous, yellowish, and semi-transparent, splitting when the flower opens, and reflected when it is fully expanded; the corolla is rotate, and deeply divided into five or six lanceolate, acute segments; the stamens are five or six and shorter than the corolla. This plant grows among the

Appenines, the Alps, the Pyrenees, and in other mountainous or elevated regions of Europe. Its root is the only part used in medicine.

Several other species of the genus possess analogous medicinal properties, and are used for similar purposes. The roots of the *G. purpurea* and *G. punctata*, growing in the same regions as the *G. lutea*, and of the *G. Pannonica*, growing in the Austrian dominions, are said to be frequently mingled with the officinal gentian, from which they are scarcely distinguishable. The *G. macrophylla* of Pallas is used in Siberia; and one indigenous species, the *G. Catesbæi*, has found a place in the secondary catalogue of the U. S. Pharmacopœia.

Gentian is imported from Germany.

Properties. As found in the shops, it is in pieces of various dimensions and shape, usually of considerable length, consisting sometimes of longitudinal slices, sometimes of the root cut transversely, twisted, wrinkled externally, sometimes marked with close transverse rings, of a grayish-brown colour on the outside, yellowish or reddish within, and of a soft spongy texture. The odour is feeble, but decided and peculiar. The taste is slightly sweetish, and intensely bitter, without being nauseous. The powder is of a yellowish colour. Water and alcohol extract the taste and medical virtues of the root. Examined by MM. Henry and Caventou, it was found to contain, 1. a peculiar crystallizable principle which they supposed to be the chief active ingredient of the root, and, therefore, named *gentianin*, 2. a volatile odorous principle, 3. a substance identical with birdlime (*glu*), 4. a greenish fixed oil, 5. a free organic acid, 6. uncrystallizable sugar, 7. gum, 8. yellow colouring matter, and 9. lignin. Mr. Denis has since detected in the root the existence of pectic acid; and the gentianin of Henry and Caventou has been proved by Trommsdorff and by M. Leconte to be, when quite pure, wholly destitute both of bitterness and of medicinal power; so that it would appear no longer to merit the name which it bears. M. Leconte proposes, accordingly, to call it *gentisin*; and, as it possesses the property of neutralizing the alkalies, it has received also the name of *gentisic acid*. It is obtained by treating the alcoholic extract of gentian previously exhausted by water, with sulphuric ether, filtering the ethereal solution, and allowing it to evaporate spontaneously. It is in needleshaped crystals, pale yellow, insoluble in water and soluble in alcohol. The same chemist believes that he has ascertained the *birdlime* or *glu* of Henry and Caventou to be a mixture of wax, oil, and caoutchouc. When distilled with water, gentian yields a minute proportion of a concrete oil, which has a strong odour of the root. Professor Dulk of Königsberg gives the following process for isolating the bitter principle. The alcoholic extract is macerated in water, and the solution, having been subjected to the vinous fermentation in order to separate the sugar, is treated first with acetate of lead, and then, after filtration, with subacetate of lead and a very little ammonia, in order to precipitate the combination of the vegetable principle with oxide of lead; care being taken not to use too much ammonia, lest by its stronger basic powers it should separate the vegetable principle from the oxide. The precipitate thus obtained is washed with a little water, then mixed with a large proportion of the same fluid, and decomposed by hydrosulphuric acid. The liquid having been filtered, is evaporated with a gentle heat to dryness, and the residue treated with alcohol of 0.820. The alcoholic solution being evaporated yields the bitter principle, which ought to receive the name of *gentianin*. It is a brownish-yellow, uncrystallizable substance, having in a high degree the bitter taste of the root. It is almost insoluble in absolute alcohol, but soluble in ordinary alcohol, and very soluble in water. It reddens litmus,

and appears to possess acid properties. (*Journ. de Pharm.* xxiv. 638.) When gentian is macerated in cold water, it undergoes the vinous fermentation, in consequence, probably, of the presence of its saccharine principle. From the fermented infusion a spirituous liquor is obtained by distillation, which, though bitter and unpleasant to the smell, is much relished by the Swiss and Tyrolese.

Medical Properties and Uses. Gentian possesses, in a high degree, the tonic powers which characterize the simple bitters. It excites the appetite, invigorates the powers of digestion, moderately increases the temperature of the body and the force of the circulation, and acts in fact as a general corroborant of the system. In very large doses, however, it is apt to load and oppress the stomach, to irritate the bowels, and even to occasion nausea and vomiting. It has been known as a medicine from the highest antiquity, and is said to have derived its name from Gentius, a king of Illyria. Many of the complex preparations handed down from the Greeks and Arabians contain it among their ingredients; and it enters into most of the stomachic combinations employed in modern practice. It may be used in all cases of disease dependent on pure debility of the digestive organs, or requiring a general tonic impression. Dyspepsia, gout, amenorrhœa, hysteria, serofula, intermittent fever, diarrhœa, and worms, are among the many forms of disease in which it has proved useful; but it is the condition of the stomach and of the system generally, not the name of the disease, which must be taken into consideration in prescribing it, and there is scarcely a single complaint in which it can be advantageously administered under all circumstances. Its powder has been applied externally to malignant and sloughing ulcers. It is usually given in the form of infusion or tincture. The dose of the powder is from ten to forty grains.

GENTIANA CATESBÆI. *U. S. Secondary.*

Blue Gentian.

“The root of *Gentiana Catesbæi*.” *U. S.*

GENTIANA. See GENTIANA.

Several indigenous species of gentian approach more or less nearly to the *Gentiana lutea* in the bitterness and medicinal virtues of their roots; but the *G. Catesbæi*, which resembles it most closely in these respects, is the only one which has attracted the particular attention of the medical profession.

Gentiana Catesbæi. Walter, *Flor. Car.* 109; Bigelow, *Am. Med. Bot.* ii. 137; Nuttall, *Gen. of Am. Plants*, i. 172. The blue gentian has a perennial, branching, somewhat fleshy root, and a simple, erect, rough stem, rising eight or ten inches in height, and bearing opposite leaves, which are ovate lanceolate, acute, and rough on their margin. The flowers, which are of a palish-blue colour, are crowded, nearly sessile, axillary and terminal. The divisions of the calyx are linear lanceolate, and longer than the tube. The corolla is large, ventricose, plaited, and divided at its border into ten segments, of which the five outer are more or less acute, the five inner bifid and fringed. The number of stamens is five, and the two stigmas are seated on the germ. The capsule is oblong, acuminate, with two valves, and a single cell.

The *G. Catesbæi* grows in the grassy swamps of North and South Carolina, where it flowers from September to December. It was named by Walter and Elliott in honour of Catesby, by whom it was imperfectly delineated upwards of seventy years ago. Pursh confounds it with the *G. saponaria*, to which it is nearly allied.

Properties. By Dr. Bigelow we are told that the dried root of this plant has at first a mucilaginous and sweetish taste, which is soon succeeded by an intense bitterness, approaching nearly to that of the officinal gentian. Alcohol and boiling water extract its virtues, and the tincture and decoction are even more bitter than the root in substance. Blue gentian has not been satisfactorily analyzed.

Medical Properties. As a medicine it is little inferior to the European gentian, and may be employed for similar purposes. In the Northern and Middle States it is not used; but it is said to be occasionally prescribed by the practitioners of the South in dyspepsia, and other cases of stomachic and general debility. It may be given in powder in the dose of fifteen or thirty grains, and may be substituted for the foreign gentian in the preparation of the officinal extract, infusion, wine, and tincture. W.

GEOFFROYA INERMIS. Cortex. Dub.

Cabbage-tree Bark.

Geoffroya de Jamaïque, *Fr.*; Jamaicanische Wurmrinde, *Ger.*; Geoffrœa, *Ital.*

The tree producing this bark was formerly placed in the genus *Geoffroya*, from which, however, it has been separated, and with a few others erected into a distinct genus entitled *Andira*, which is now generally admitted by botanists.

ANDIRA *Sex. Syst.* Diadelphia Decandria.—*Nat. Ord.* Leguminosæ or Fabacæ.

Gen. Ch. *Calyx* turbinate-campanulate, five-toothed; teeth nearly equal, acute, erect. *Corolla* papilionaceous; the vexillum roundish, emarginate, longer than the keel. *Stamens* diadelphous. *Ovary* with three ovules. *Legume* stipitate, roundish, rather hard, one-celled, one-seeded, when ripe divisible into two valves. (*De Cand.*)

Andira inermis. De Cand. *Prodrom.* ii. 475.—*Geoffroya inermis.* Willd. *Sp. Plant.* iii. 1130; Woodv. *Med. Bot.* p. 416. t. 151. The stem of this tree, which rises to a considerable height, is branched towards the top, and covered with a smooth gray bark. The leaves are pinnate, consisting of six or seven pairs of ovate lanceolate, pointed, veined, smooth, petiolate leaflets, with an odd one at the end. The flowers are rose-coloured, and arranged in terminal panicles, with very short pedicels. The cabbage-tree is a native of Jamaica and other West India islands. The bark is the part used.

On the continent of Europe the bark of the *Andira retusa* (*Geoffroya Surinamensis*), which grows in Surinam, has also been employed. It is considered more powerfully vermifuge, without being equally liable to produce injurious effects.

Cabbage-tree bark is in long pieces, thick, fibrous, externally of a brownish-ash colour, scaly and covered with lichens, internally yellowish, of a resinous fracture, a disagreeable smell, a sweetish, mucilaginous, bitterish taste, and affording a powder resembling that of jalap. Huttenschmidt obtained from it a crystallizable, very bitter substance, having the composition and neutralizing properties of the vegetable alkaloids, and named very

inappropriately *jamaicina*. Two grains of it produced violent purging in pigeons.

The bark of the *A. retusa* has a grayish epidermis, beneath which it is reddish-brown, laminated, compact, very tenacious, and when cut transversely exhibits a shining and variegated surface. In the dried state it is inodorous, but has an austere bitter taste. The powder is of a pale cinnamon colour.

Medical Properties and Uses. Cabbage-tree bark is cathartic, and in large doses is apt to occasion vomiting, fever, and delirium. It is said that these effects are more liable to result if cold water is drunk during its operation, and are relieved by the use of warm water, castor oil, or a vegetable acid. In the West Indies the bark is esteemed a powerful vermifuge, and is much employed for expelling lumbrici; but it is dangerous if incautiously administered, and instances of death from its use have occurred. It is almost unknown in this country, and does not enter into our official catalogues. The usual form of administration is that of decoction, though the medicine is also given in powder, syrup, and extract. The dose of the powder is from a scruple to half a drachm, of the extract three grains, of the decoction two fluidounces.

W.

GERANIUM. U.S.

Cranesbill.

“The root of *Geranium maculatum*.” *U. S.*

GERANIUM. *Sex. Syst.* Monadelphia Decandria.—*Nat. Ord.* Geraniaceæ.

Gen. Ch. *Calyx* five-leaved. *Corolla* five petaled, regular. *Nectary* five melliferous glands united to the base of the longer filaments. *Arilli* five, one-seeded, awned, at the base of a beaked receptacle; awns simple, naked, neither spiral nor bearded. *Willd.*

Geranium maculatum. Willd. *Sp. Plant.* iii. 705; Bigelow, *Am. Med. Bot.* i. 84; Barton, *Med. Bot.* i. 149. This plant has a perennial, horizontal, fleshy root, which is furnished with short fibres, and sends up annually an herbaceous stem, with several radical leaves. The stem is erect, round dichotomously branched, from one to two feet high, of a grayish-green colour, and thickly covered, in common with the petioles and peduncles, with reflexed hairs. The leaves are deeply divided into three, five, or seven lobes, which are variously incised at their extremities, hairy, and of a pale green colour, mottled with still paler spots. Those which rise immediately from the root are supported on footstalks eight or ten inches long; those of the stem are opposite, the lower petiolate, the upper nearly sessile, with lanceolate or linear stipules. The flowers are large, and usually of a purple colour. The peduncles spring from the forks of the stem, and severally support two flowers upon short pedicels. The calyx is composed of five oblong, ribbed, cuspidate leaves; the petals are five, obovate, and entire; the stamens ten, with oblong deciduous anthers, the five alternate filaments being longer than the others, and having glands at their base; the germ is ovate, supporting a straight style as long as the stamens, and surmounted by five stigmas. The fruit consists of five aggregate, one-seeded capsules, attached by a beak to the persistent style, curling up and scattering the seeds when ripe.

The cranesbill is indigenous, growing throughout the United States, in

moist woods, thickets and hedges, and generally in low grounds. It flowers from May to July. The root should be collected in autumn.

This, when dried, is in pieces from one to three inches long, from a quarter to half an inch in thickness, somewhat flattened, contorted, wrinkled, tuberculated, and beset with slender fibres. It is externally of an umber-brown colour, internally reddish-gray, compact, inodorous, and of an astringent taste, without bitterness or other unpleasant flavour. Water and alcohol extract its virtues. Tannin is an abundant constituent.

Medical Properties and Uses. Geranium is one of our most powerful indigenous astringents, and may be employed for all the purposes to which these medicines are applicable. The absence of unpleasant taste and all other offensive qualities, renders it peculiarly serviceable in the cases of infants, or of persons with very delicate stomachs. Diarrhœa, chronic dysentery, cholera infantum in the latter stages, and the various hemorrhages, are the forms of disease in which it is most commonly used and with greatest advantage; but care should be taken, before it is administered, that the condition of the system and of the part affected is such as not to contraindicate the use of astringents. As an application to indolent ulcers, an injection in gleet and leucorrhœa, a gargle in relaxation of the uvula and aphthous ulcerations of the throat, it answers the same purpose with kino, catechu, and other foreign remedies of similar character. It is a popular domestic remedy in various parts of the United States, and is said to be employed by the Indians in numerous disorders. It may be given in substance, decoction, tincture, or extract. The dose of the powder is twenty or thirty grains, that of a decoction made by boiling an ounce of the root in a pint and a half of water to a pint, from one to two fluidounces. The medicine is sometimes given to children boiled in milk. W.

GEUM. U. S. Secondary.

Water Avens.

“The root of Geum rivale.” U. S.

Benoite aquatique, Fr.; Wiesen-Benediktenwurz, Germ.

GEUM. Sex. Syst. Icosandria Polygynia.—Nat. Ord. Rosaceæ.

Gen. Ch. Calyx ten-cleft. Petals five. Seeds with a bent awn. Willd.

Several species belonging to this genus have been medicinally employed; but two only are deserving of particular notice—the *Geum rivale*, which has a place in the secondary list of the United States Pharmacopœia, and the *G. urbanum*, recognised by the Dublin College.

Geum rivale. Willd. Sp. Plant. ii. 1115; Engl. Bot. 106. The water avens has a perennial, horizontal, jointed, scaly, tapering root, about six inches long, of a reddish-brown colour externally, white internally, and furnished with numerous descending yellowish fibres. Sometimes one, sometimes several stems rise from the same root, which also sends up numerous leaves. The stems are about a foot and a half high, simple, erect, pubescent, and of a purplish colour. The radical leaves are interruptedly pinnate, with large terminal leaflets, and stand on long, hairy footstalks; those of the stem are petiolate, and divided into three serrate, pointed segments. The flowers are few, solitary, nodding, yellowish-purple, and supported on axillary and terminal peduncles. The colour of the stems and flowers has given rise to the name of *purple avens*, by which the plant is sometimes called. The calyx is inferior, with ten lanceolate pointed segments, of which the five alternate are smaller than the others. The petals are five, and of the same

length as the calyx. The seeds are oval, and furnished with plumose awns, minutely uncinatè, and nearly naked at the summit.

This species of Geum is common to Europe and the United States; though the plant of this country has smaller flowers, with petals more rounded on the top, and leaves more deeply incised than the European. It delights in wet boggy meadows, and extends from Canada into New England, New York, and Pennsylvania. Its flowers appear in June and July.

The dried root is hard, brittle, easily pulverized, of a reddish or purplish colour, without smell, and of an astringent, bitterish taste. Boiling water extracts its virtues.

Medical Properties and Uses. Water avens is tonic and powerfully astringent. It may be used with advantage in chronic or passive hemorrhages, leucorrhœa, and diarrhœa; and is said to be beneficially employed, in the Eastern States, as a popular remedy in the debility of phthisis pulmonalis, in simple dyspepsia, and in visceral diseases consequent on disorder of the stomach. In Europe it is sometimes substituted for the root of the common avens, or Geum urbanum, but is less esteemed. The dose of the powdered root is from a scruple to a drachm, to be repeated three times a day. The decoction, which is usually preferred, may be made by boiling an ounce of the root in a pint of water, and given in the quantity of one or two fluidounces. A weak decoction is sometimes used by invalids in New England as a substitute for tea and coffee. W.

GEUM URBANUM. Radix. Dub.

Root of Avens.

Benoite, *Fr.*; Benediktenwurzel, *Germ.*; Cariofillata, *Ital.*; Cariofilata, *Span.*

GEUM. See GEUM.

Geum urbanum. Willd. *Sp. Plant.* ii. 1113; Woodv. *Med. Bot.* p. 502. t. 181. Avens is an herbaceous perennial plant, with slender, erect, branching, hairy stems, about two feet in height. The leaves are petiolate, serrate, hairy; those on the upper part of the stem, simple, trifid, and pointed; those nearest the root, pinnate and lyrate, with two pairs of unequal leaflets, and a larger terminal leaflet, which is usually three-lobed. The flowers are small, of a bright yellow colour, and solitary upon erect terminal peduncles. The seeds, which are hairy and collected in a roundish head, have at their summit a naked awn, bent like a hook at the apex.

This species of Geum is a native of Europe, where it grows in woods and shady uncultivated places. The flowers appear in June and July. The root, which is the part employed, should be dug up in March, when its sensible properties are in greatest perfection, and should be dried by a moderate heat. The large roots are preferred to those which are very small, and the cultivated to the wild.

The avens root consists of a short oblong body or caudex, from a quarter to half an inch in thickness, externally brown, internally white towards the circumference, and reddish at the centre, and sending forth numerous long brown descending fibres. When quite dry it is nearly inodorous, but in the recent state it has a smell resembling that of cloves, whence it is sometimes called *radix caryophyllatæ*. Its taste is bitterish and astringent. It imparts its medicinal virtues to water and alcohol, which it tinges red. Distilled with water it yields a thick, greenish-yellow volatile oil, and gives a pleasant flavour to the liquid. Tannin is an abundant constituent. It contains, moreover, according to Trommsdorff, an insipid resin, gum, bassorin, and lignin.

Medical Properties and Uses. This root has been largely used on the continent of Europe as a tonic and astringent in numerous diseases. Among these are chronic and passive hemorrhages, chronic dysentery and diarrhœa, leucorrhœa, congestions of the abdominal viscera, and intermittent fever. The dose of the powdered root is from thirty grains to a drachm three or four times a day, and the same quantity may be given at a dose in the form of decoction. The medicine is scarcely used in the United States. W

GILLENIA. U.S.

Gillenia.

“The root of *Gillenia trifoliata*. U. S.

Indian physic, American ipecacuanha.

GILLENIA. *Sex. Syst.* Icosandria Pentagynia.—*Nat. Ord.* Rosacæ.

Gen. Ch. *Calyx* tubular campanulate, border five-toothed. *Corolla* partly unequal. *Petals* five, lanceolate, attenuated at the base. *Stamens* few, included. *Styles* five. *Capsules* five, connate at the base, opening on the inner side, each two-seeded. *Torrey.*

This genus was separated by Moench from the *Spiræa*, but was not generally acknowledged till after the publication of Barton's Medical Botany. It is exclusively North American, and includes only two discovered species—the *G. trifoliata* and *G. stipulacea*—of which the former only has been adopted in our Pharmacopœia, though the two are identical in medical character.

1. *Gillenia trifoliata*. Bigelow, *Am. Med. Bot.* iii. 10; Barton, *Med. Bot.* i. 65. This is an herbaceous plant with a perennial root, consisting of numerous long, slender, brown branches, proceeding from a thick tuber-like head or caudex. The stems, several of which usually rise from the same root, are two or three feet in height, erect, slender, smooth, flexuose, branched, and commonly of a reddish colour. The leaves are ternate, with very short petioles, and small linear lanceolate stipules. The leaflets are ovate lanceolate, sharply serrate, and acuminate. The flowers grow in a loose terminal nodding panicle, with long peduncles. The calyx is tubular campanulate, ventricose, and terminates in five pointed segments. The corolla is composed of five linear lanceolate, recurved petals, the two upper separated from the three lower, white, with a reddish tinge on their border, and of three times the length of the calyx. The stamens are twenty, the filaments short, the anthers small and yellow. Each flower is succeeded by five capsules, connate at their base, oblong, acuminate, gibbous without, acute within, two-valved, one-celled, opening inward, and containing each one or two oblong seeds.

This species of *Gillenia* grows throughout the United States, east of the Alleghany ridge, and in Pennsylvania may also be found abundantly west of these mountains. Pursh found it in Florida, and it extends as far north as Canada. It frequents light soils, in shady and moist situations, and flowers in June and July. The root should be gathered in September.

2. *G. stipulacea*. Barton, *Med. Bot.* i. 71. This species is also herbaceous and perennial, though much taller, and more bushy than the preceding. The stems are brownish and branched. The upper leaves are ternate, lanceolate, serrate; the lower more deeply incised, becoming towards the root pinnatifid, and of a reddish-brown colour at the margin. The stipules are ovate, acuminate, deeply serrate, resembling leaves, and marking the

species at the first glance. The flowers are smaller than those of the *G. trifoliata*, and grow on long slender peduncles in a lax corymb.

In the valley of the Mississippi this plant occupies the place of the *G. trifoliata*, which is not found beyond the Muskingum. It grows as far north as the state of New York, extends through Ohio, Indiana, Illinois, and Missouri, and probably into the states south of the Ohio, as it has been found in Western Virginia. Its root is precisely similar to that of the eastern species, and is reputed to possess the same properties.

The dried root of *Gillenian* is not thicker than a quill, wrinkled longitudinally, with occasional transverse fissures, and in the thicker pieces presenting in some places an irregular undulated somewhat knotty appearance, arising from indentations on one side corresponding with prominences on the other. It is externally of a light brown colour, and consists of a thick, somewhat reddish, brittle, cortical portion, with an interior slender, tougher, whitish ligneous cord. The bark, which is easily separable, has a bitter, not disagreeable taste; the wood is nearly insipid and comparatively inert, and should be rejected. The powder is of a light brownish colour, and possesses a feeble odour which is scarcely perceptible in the root. The bitterness is extracted by boiling water, which acquires the red colour of wine. The root has not been accurately analyzed.

Medical Properties and Uses. *Gillenian* is a mild and efficient emetic, and, like most other substances belonging to the same class, occasionally acts upon the bowels. In very small doses it has been thought to exert a tonic influence. It is much used by some practitioners in the country, as a substitute for ipecacuanha, which it is said to resemble in its mode of operation. It was employed by the Indians, and became known as an emetic to the colonists at an early period. Linnæus was aware of its reputed virtues. The dose of the powdered root is from twenty to thirty grains, repeated at intervals of twenty minutes till it vomits. W.

GLYCYRRHIZA. U.S., Lond.

Liquorice Root.

“The root of *Glycyrrhiza glabra*.” U.S. “*Glycyrrhiza glabra*. *Radix recens*.” Lond.

Off. Syn. GLYCYRRHIZÆ RADIX. Root of *Glycyrrhiza glabra*. *Ed.*; GLYCYRRHIZA GLABRA. *Radix. Dub.*

Bois de réglisse, *Fr.*; Süß-holzwurzel, *Germ.*; Liquirizia, *Ital.*; Regaliza, *Span.*

GLYCYRRHIZA. *Sex. Syst.* Diadelphia Decandria.—*Nat. Ord.* Leguminosæ or Fabaceæ.

Gen. Ch. *Calyx* bilabiate; upper lip three-cleft, lower undivided. *Legume* ovate, compressed. *Willd.*

Glycyrrhiza glabra. Willd. *Sp. Plant.* iii. 1144; Woodv. *Med. Bot.* p. 420. t. 152. The liquorice plant has a perennial root, which is round, succulent, tough, and pliable, furnished with sparse fibres, rapid in its growth, and in a sandy soil penetrates deeply into the ground. The stems are herbaceous, erect, and usually four or five feet in height; have few branches; and are garnished with alternate, pinnate leaves, consisting of several pairs of ovate, blunt, petiolate leaflets, with a single leaflet at the end, of a pale green colour, and clammy on their under surface. The flowers are violet or purple, formed like those of the pea, and arranged in axillary spikes supported on long peduncles. The calyx is tubular and persistent. The fruit is a compressed, smooth, acute, one-celled legume, containing from one to four small kidney-shaped seeds.

The plant is a native of the South of Europe, Barbary, Syria, and Persia; and is cultivated in England, the North of France, and Germany. Much of the root imported into this country comes from the ports of Messina and Palermo in Sicily. It is also largely produced in the northern provinces of Spain, where it forms an important article of commerce. It is not improbable that a portion of the liquorice root from Italy and Sicily is the product of the *G. echinata*, which grows wild in Apulia. This species is also abundantly produced in the South of Russia, where, according to Hayne, sufficient extract is prepared from it to supply the whole Russian empire.

A species of *Glycyrrhiza*, the *G. lepidota*, grows abundantly about St. Louis, in the state of Missouri, and flourishes along the banks of the Missouri river to its source in the mountains. It is probably the same with the liquorice plant mentioned by Mackenzie as growing on the northern coast of this continent. Mr. Nuttall states that its root possesses in no inconsiderable degree the taste of liquorice; and it is not improbable that it may be found a fit substitute for that of the *G. glabra*.

Properties. The liquorice root of the shops is in long pieces, varying in thickness from a few lines to more than an inch, fibrous, externally grayish-brown, and wrinkled by desiccation, internally yellowish, without smell, and of a sweet mucilaginous taste, which is sometimes mingled with a slight degree of acrimony. It is often worm-eaten and more or less decayed. The best pieces are those which have the brightest yellow colour internally, and of which the layers are distinct. The powder is of a grayish-yellow colour when the root is pulverized without being deprived of its epidermis, of a pale sulphur yellow, when the epidermis has been removed. Robiquet found the following ingredients in liquorice root:—1. A peculiar transparent yellow substance, called *glycyrrhizin* or *glycion*, of a sweet saccharine taste, scarcely soluble in cold water, very soluble in boiling water with which it gelatinizes on cooling, thrown down from its aqueous solution by acids, readily soluble in cold alcohol, insusceptible of the vinous fermentation, yielding no oxalic acid by the action of the nitric, and therefore wholly distinct from sugar; 2. a crystallizable principle, named *agedoïte* by Robiquet, but subsequently proved to be identical with *asparagin*; 3. starch; 4. albumen; 5. a brown, acrid resin; 6. a brown, azotized extractive matter; 7. lignin; 8. salts of lime and magnesia with phosphoric, sulphuric, and malic acids. Robiquet prepared *glycyrrhizin* by subjecting a strong cold infusion of the root to ebullition, in order to separate the albumen; then filtering, precipitating with acetic acid, and washing the precipitate with cold water to remove any adhering acid. Berzelius considers the matter thus obtained as a compound of *glycyrrhizin* with acetic acid. He procures the principle in a pure state by precipitating with sulphuric acid an infusion of the root previously concentrated by a gentle heat, washing the precipitated sulphate to remove the free acid which adheres to it, then dissolving it in alcohol, which leaves the albumen, and adding carbonate of potassa to the alcoholic solution to perfect neutralization. The sulphate of potassa is precipitated, and the *glycyrrhizin* is obtained by evaporating the alcohol. The sweetness of this principle is retained in the compounds which it forms both with acids and alkalies.

An extract of liquorice root is brought from Spain and Italy, and much used under the name of liquorice. (See *Extractum Glycyrrhizæ*.)

Medical Properties and Uses. Liquorice root is an excellent demulcent, well adapted to catarrhal affections, and to irritations of the mucous membrane of the bowels and urinary passages. It is best given in the form of decoction, either alone, or combined with other demulcents. It is frequently

employed as an addition to the decoctions of acrid or irritating vegetable substances, such for example as seneka and mezereon, the acrimony of which it covers and conceals, while it renders them more acceptable to the stomach. Before being used, it should be deprived of its cortical part, which is somewhat acrid, without possessing the peculiar virtues of the root. The decoction may be prepared by boiling an ounce of the bruised root for a few minutes in a pint of water. By long boiling, the acrid principle is extracted.

The powder is used in the preparation of pills, either to give them due consistence, or to cover their surface and prevent them from adhering together.

GOSSYPIUM. *Ed.*

Raw Cotton.

“Hairs attached to the seeds of *Gossypium herbaceum*, and other species of the genus.” *Ed.*

Coton, Fr.; Baumwolle, Germ.; Cotone, Ital.; Algodon, Span.

GOSSYPIUM. Sex. Syst. Monadelphia Polyandria.—Nat. Ord. Malvaceæ.

Gen. Ch. *Calyx* cup-shaped, obtusely five-toothed, surrounded by a three-parted involucre, with dentate-incised, cordate leaflets, cohering at the base. *Stigmas* three to five. *Capsule* three to five-celled, many-seeded. *Seeds* surrounded by a tomentose wool. *De Cand.*

In consequence of changes produced in the plants of this genus by cultivation, botanists have found great difficulty in determining which are distinct species, and which merely varieties. De Candolle describes thirteen species in his *Prodromus*, and mentions six others; but considers them all uncertain. Royle describes eight and admits others. Swartz thinks they may all be referred to one original species. The plants inhabit different parts of tropical Asia and Europe, and many of them are cultivated for their cotton in climates adapted to their growth. The species from which most of the cotton of commerce is thought to be obtained, is the one indicated by the *Edinburgh Pharmacopœia*.

Gossypium herbaceum. *Linn. Sp.* 975; *De Cand. Prodrom.* i. 456. This is a biennial or triennial plant, with a branching stem from two to six feet high, and palmate hoary leaves, the lobes of which are somewhat lanceolate and acute. The flowers are pretty, with yellow petals, having a purple spot near the claw. The leaves of the involucre or outer calyx are serrate. The capsule opens when ripe, and displays a loose white tuft of long slender filaments, which surround the seeds, and adhere firmly to the outer coating. The plant is a native of Asia, but is cultivated in most tropical countries both of the old and new continents. It requires a certain duration of warm weather to perfect its seeds, and cannot be cultivated for practical purposes north of Virginia.

The herbaceous part of the plant contains much mucilage, and has been

used as a demulcent. The seeds yield by expression a fixed oil of the drying kind, which has been occasionally employed. The root has been supposed to possess medical virtues. But the only officinal portion, and that for which the plant is cultivated, is the filamentous matter surrounding the seeds. This when separated constitutes the cotton of commerce.

Cotton consists of the filaments which, under the microscope, appear to be flattened tubes, with occasional joints indicated by transverse lines. It is without smell or taste, insoluble in water, alcohol, ether, the oils, and vegetable acids, soluble in strong alkaline solutions, and decomposed by the concentrated mineral acids. It has not been analyzed, but bears a close analogy to lignin. For medical use it should be carded into thin sheets; or the wadding of the milliners may be employed, consisting of sheets somewhat stiffened and glazed on the surface by starch. In the latter case, the sheets should be split open when applied.

Uses. Cotton has been used from time immemorial for the fabrication of cloth; but it is only recently that it has entered the catalogue of medicines. It is chiefly employed in the treatment of recent burns and scalds; an application of it which was adopted by surgeons from popular practice. It is said to relieve the pain, diminish the inflammation, prevent vesication, and very much to hasten the cure. Whatever advantages result from it are probably ascribable to the absorption of effused liquids, and the protection of the part affected from the air. It is applied in thin and successive layers; and benefit is said to result from the application of a bandage when the skin is not too much inflamed. We have, however, seen cotton do much harm in burns, by becoming consolidated over a vesicated surface, and acting as a mechanical irritant. It is said to be beneficial also in erysipelas; and we have found it useful, applied in a large batch over parts affected with rheumatism, especially in lumbago.

The root of the cotton plant has been employed by Dr. Bouchelle, of Mississippi, who believes it to be an excellent emmenagogue, and not inferior to ergot in promoting uterine contraction. He states that it is habitually and effectually resorted to by the slaves of the South for producing abortion; and thinks that it acts in this way, without affecting the general health injuriously. To assist labour, he employs a decoction made by boiling four ounces of the inner bark of the root in a quart of water to a pint, and gives a wineglassful every twenty or thirty minutes. (*West. Journ. of Med. and Surg. Aug. 1840.*) These statements need confirmation. W.

PUNICA. *Sex. Syst.* Icosandria Monogynia.—*Nat. Ord.* Myrtaceæ.

Gen. Ch. *Calyx* five-cleft, superior. *Petals* five. *Pome* many-celled, many-seeded. *Willd.*

Punica Granatum. Willd. *Sp. Plant.* ii. 981; Woodv. *Med. Bot.* p. 531. t. 190. The pomegranate is a small shrubby tree, attaining in favourable situations the height of twenty feet, with a very unequal trunk, and numerous branches, which sometimes bear thorns. The leaves are opposite, entire, oblong or lance-shaped, pointed at each end, smooth, shining, of a bright green colour, and placed on short footstalks. The flowers are large, of a rich scarlet colour, and stand at the end of the young branches. The petals are roundish and wrinkled, and are inserted into the upper part of the tube of the calyx, which is red, thick, and fleshy. The fruit is a globular berry, about the size of an orange, crowned with the calyx, covered with a reddish-yellow, thick, coriaceous rind, and divided internally into many cells, which contain an acidulous pulp, and numerous oblong, angular seeds.

This tree grows wild upon both shores of the Mediterranean, in Arabia, Persia, Bengal, China, and Japan, has been introduced into the East and West Indies, and is cultivated in all civilized countries where the climate is sufficiently warm to allow the fruit to ripen. In higher latitudes, where it does not bear fruit, it is raised in gardens and hot-houses for the beauty of its flowers, which become double, and acquire increased splendour of colouring by cultivation. Doubts have been entertained as to its original country. The name of "*Punicum malum*," applied by the ancients to its fruit, implies that it was abundant at an early age in the neighbourhood of Carthage. The fruit of the pomegranate, for which the plant is cultivated in tropical climates, varies much in size and flavour. It is said to attain greater perfection, in both these respects, in the West Indies than in its native country. The pulp is red, succulent, pleasantly acid, and sweetish; and is used for the same purpose as the orange, though not officinal. The rind of the fruit and the bark of the root are the parts indicated in the United States Pharmacopœia. The flowers also are recognised by the Dublin College, and the seeds are officinal in France.

Rind of the Fruit. This is presented in commerce under the form of irregular fragments, hard, dry, brittle, of a yellowish or reddish-brown colour externally, paler within, without smell, and of an astringent slightly bitter taste. It contains a large proportion of tannin, and in countries where the tree abounds has been employed for tanning leather.

Flowers. The flowers, which are sometimes called *balaustines*, are inodorous, have a bitterish strongly astringent taste, and impart a violet-red colour to the saliva. They contain tannin and gallic acid, and were used by the ancients in dyeing.

Bark of the Root. The roots of the pomegranate are hard, heavy, knotty, ligneous, and covered with a bark which is yellowish-gray, or ash-gray on the outer surface, and yellow on the inner. As found in the shops, the bark is in quills or fragments, breaks with a short fracture, has little or no smell, when chewed colours the saliva yellow, and leaves in the mouth an astringent taste, without any disagreeable bitterness. It contains, according to M. Latour de Trie, fatty matter, tannin, gallic acid, a saccharine substance having the properties of *mannite*, resin, wax, and chlorophylle, besides insoluble matters. The infusion yields a deep blue precipitate with the salts of iron, and a yellowish-white precipitate, with a solution of gelatin. These properties serve to distinguish this bark from those of the box root and barberry, with which it is said to be sometimes

adulterated. When used it should be entirely separated from the ligneous portion of the root, as the latter is inert.

Medical Properties and Uses. The rind of the fruit is astringent, and in the form of decoction may be given in diarrhœa from weakness of the secreting vessels, and in the colliquative sweats of hectic fever or simple debility. But the decoction is more frequently used as an injection in leucorrhœa, and as a gargle in sorethroat in the earliest stages, or after the inflammatory action has in some measure subsided. The powdered rind has also been recommended in intermittent fever. The flowers have the same medical properties, and are used for the same purposes as the rind. The bark of the root was used by the ancients as a vermifuge, and is recommended in the writings of Avicenna; but it was unknown in modern practice till brought into notice by Dr. F. Buchanan, who obtained his knowledge of its powers in India. The Mahometan physicians of Hindostan consider it a specific in cases of tape-worm. One of these practitioners having speedily relieved an English gentleman in 1804, was induced to disclose his secret, which was then made public. Numerous cures have been subsequently effected in Europe; and there can be no doubt of the occasional efficacy of the remedy. The French medical writers prefer the bark of the root of the wild pomegranate, or that which grows on the borders of the Mediterranean, to the product of the imperfect tree cultivated for ornamental purposes in the gardens of colder countries. It may be administered in powder or decoction; but the latter form is usually preferred. The decoction is prepared by macerating two ounces of the bruised bark in two pints of water for twenty-four hours, and then boiling down to a pint. Of this a wine-glassful may be given every half hour, hour, or two hours, until the whole is taken. It often occasions nausea and vomiting, and usually purges. Portions of the worm often come away a short time after the last dose. It is recommended to give a dose of castor oil, and to diet the patient strictly on the day preceding the administration of the remedy; and, if it should not operate on the bowels, to follow it by an enema, or a dose of castor oil. If the remedy should not succeed upon the first trial, it should be repeated every day for three or four days, until the worm is discharged. The remedy appears to have been used by the negroes of St. Domingo before it was introduced into Europe. *Tænia* is comparatively rare in this country; and the pomegranate root has been little used.

The dose of the rind and flowers in powder is from twenty to thirty grains. A decoction may be prepared in the proportion of an ounce of the medicine to a pint of water, and given in the dose of a fluidounce. The seeds are demulcent.

GUAIACUM. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Zygophyllaceæ.

Gen. Ch. Calyx five-cleft, unequal. *Petals* five, inserted into the calyx. *Capsule* angular, three or five-celled. *Willd.*

Guaiacum officinale. Willd. *Sp. Plant.* ii. 538; Woodv. *Med. Bot.* p. 557. t. 200. This is a large tree of very slow growth. When of full size it is from forty to sixty feet high, with a trunk four or five feet in circumference. The branches are knotted, and covered with an ash-coloured striated bark. That of the stem is of a dark gray colour, variegated with greenish or purplish spots. The leaves are opposite, and abruptly pinnate, consisting of two, three, and sometimes four pairs of leaflets, which are obovate, veined, smooth, shining, dark green, from an inch to an inch and a half long, and almost sessile. The flowers are of a rich blue colour, stand on long peduncles, and grow to the number of eight or ten at the axils of the upper leaves. The seeds are solitary, hard, and of an oblong shape.

The *G. officinale* grows in the West Indies, particularly in Hayti and Jamaica, and is found also in the warmer parts of the neighbouring continent. All parts of the tree are possessed of medicinal properties, but the wood and the concrete juice only are officinal. The bark, though much more efficacious than the wood, is not kept in the shops. It is said that other species of *Guaiacum* contribute to the supplies brought into the market. The *G. sanctum* of Linnæus, and the *G. arboreum* of De Candolle, are particularly specified. The former, however, is said by Woodville not to be sufficiently characterized as a distinct species from the *G. officinale*. Fée states that the wood of the *G. sanctum* is paler, and less heavy and hard than the officinal.

Guaiacum wood is imported from Hayti and other West India islands, in the shape of logs or billets, covered with a thick gray bark, which presents on its inner surface, and upon its edges when broken, numerous shining crystalline points. These are supposed by M. Guibourt to be benzoic acid, by others a resinous exudation from the vessels of the plant. These billets are used by the turners for the fabrication of various instruments and utensils, for which the wood is well adapted by its extreme hardness and density. It is kept by the druggists and apothecaries only in the state of shavings or raspings, which they obtain from the turners. It is commonly called *lignum vitæ*, a name which obviously originated from the supposition that the wood was possessed of extraordinary remedial powers.

Properties. The colour of the alburnum or sap-wood is yellow, that of the older and central layers greenish-brown, that of the shavings a mixture of the two. It is said that when the wood is brought into a state of minute division, the colour is rendered green by exposure to the air (*Richard*), and bluish-green by the action of nitric acid fumes; and the latter change may be considered as a test of the genuineness of the drug. (*Duncan*). *Guaiacum* wood is almost without smell unless rubbed or heated, when it becomes odorous. When burnt it emits an agreeable aromatic odour. It is bitterish and slightly pungent; but requires to be chewed for some time before the taste is developed. It contains, according to Trommsdorff, 26 per cent. of resin, and 0.8 of a bitter pungent extractive, upon both of which probably, though chiefly on the former, its medical virtues depend. (See *Guaiacum*.) It yields its virtues but partially to water. One pound of the wood afforded to Geiger two ounces of extract. In this extract M. Thierry has discovered a peculiar volatilizable acid, resembling benzoic and cinnamic acids. He obtained it by treating the extract with ether, evaporating the ethereal tincture, and carefully subliming the residue. The acid condenses in small, brilliant needles. If the heat be pushed too far, an oil is also produced which colours the crystals. To this acid M. Thierry has given the name of *guaiacic acid* (*acide gayacique*). He procured the same acid more abundantly from the *guaiac* of the shops, by a somewhat complicated process. (See *Journ. de Pharm.* xxvii. 381.)

Medical Properties and Uses. Guaiacum wood ranks among the stimulant diaphoretics. It is said to have been introduced to the notice of European practitioners by the natives of Hispaniola, soon after the discovery of America. It was used in Europe so early as 1508, and attained great celebrity as a remedy for lues venerea, in which it was long considered a specific. More extended experience, however, has proved it to be wholly inadequate to the cure of that disease; and it is now employed simply to palliate the secondary symptoms, to assist the operation of other and more efficient remedies, or to obviate the unpleasant effects sometimes resulting from a mercurial course in syphilitic cases. It is thought to be useful also in chronic rheumatism and gout, scrofulous affections, certain cutaneous eruptions, ozæna, and other protracted diseases dependent on a depraved or vitiated condition of the system. It is always exhibited in decoction, and generally in combination with other medicines, as in the compound decoction of sarsaparilla. As but a small proportion of the guaiac which it contains is soluble in water, the probability is that its virtues have been greatly overrated; and that the good which has in many instances followed its employment, resulted rather from the more active medicines with which it was associated, or from the attendant regimen, than from the wood itself. The simple decoction may be prepared by boiling an ounce in a pint and a half of water down to a pint, the whole of which may be administered in divided doses during the twenty-four hours. An aqueous extract of guaiacum wood is directed by the French Codex.

GUAIACI RESINA. *U. S.*, *Lond.*

Guaiac.

“The concrete juice of *Guaiacum officinale*.” *U. S.* “*Guaiacum officinale. Resina.*” *Lond.*

Off. Syn. GUAIACUM. Resin obtained by heat from the wood of *Guaiacum officinale*. *Ed.*; GUAIACUM OFFICINALE. *Resina. Dub.* Résine de gayac, *Fr.*; Guajakharz, *Germ.*; Resina de guajaco, *Ital.*; Resina de guayaco, *Span.*

For a description of the *Guaiacum officinale*, see GUAIACI LIGNUM.

Guaiac is the concrete juice of this tree, obtained either by spontaneous exudation, or by incisions made into the trunk. It is also procured by sawing the wood into billets about three feet long, boring them longitudinally with an auger, then placing one end of the billet on the fire, and receiving in a calabash the melted guaiac, which flows out through the hole at the opposite extremity. Another mode, occasionally practised, is to boil the wood in the state of chips or saw-dust, in a solution of common salt, and skim off the matter which rises to the surface. Guaiac is brought to this market from the West Indies. It is usually in large irregular pieces of various size, in which small fragments of bark, sand, and other earthy impurities are mixed with the genuine guaiac, so as to give to the mass a diversified appearance. Sometimes we find it in small roundish portions, separate, or agglutinated together, and evidently the result of exudation; sometimes in homogeneous masses, prepared by melting and straining the drug in its impure state. It is probable that the guaiac, obtained from the billets of wood in the manner above described, is also of uniform consistence.

Properties. The pieces are of a deep greenish-brown or dark olive colour on their external surface, and internally wherever the air has been able to penetrate. The predominant hue of those parts not exposed to the air is reddish-brown or hyacinthine, diversified, however, with shades of various colours. The odour is feeble but fragrant, and is rendered stronger by heat. The taste, which is at first scarcely perceptible, becomes acrid after a short period, and a permanent sense of heat and pungency is left in the mouth and fauces. Guaiac is brittle, and when broken presents a shining glass-like surface, conchoidal or splintery, with the smaller fragments more or less translucent. It is readily pulverized; and the powder, which is at first of a light-gray colour, becomes green on exposure to the light. Its specific gravity varies from 1.2 to 1.23. It softens in the mouth, and melts with a moderate heat. It is commonly, though erroneously, called *gum guaiac*, as it does not essentially contain gum. According to the analysis of Mr. Brande it consists of 91 per cent. of a peculiar substance analogous to the resins, and 9 per cent. of extractive. Buchner found 79.8 parts of pure resin, and 20.1 of bark consisting of 16.5 of lignin, 1.5 of gum, and 2.1 of extractive; but he must have operated on the unstrained guaiac. M. Thierry has discovered a peculiar acid in guaiac. (See page 360.) Water dissolves a small proportion of guaiac, not exceeding 9 parts in 100, forming an infusion of a greenish-brown colour and sweetish taste, which upon evaporation yields a brown substance soluble in hot water and alcohol, but scarcely so in ether. Alcohol takes up the whole, with the exception of impurities. The tincture is of a deep-brown colour, is decomposed by water, and affords blue, green, and brown precipitates with the mineral acids. Guaiac is soluble also in ether, in alkaline solutions, and in sulphuric acid. The solution in sulphuric acid is of a rich claret colour, deposits, when diluted with water, a lilac precipitate, and when heated evolves charcoal. Nitric acid converts it into oxalic acid. Exposed to air and light it absorbs oxygen and becomes green, and the change of colour takes place rapidly in the sunshine. Either in substance or tincture, it imparts a blue colour to gluten and substances containing it, to mucilage of gum Arabic, to milk, and to various freshly cut roots, as the potato, carrot, and horseradish. The tincture is usually coloured blue by spirit of nitric ether, and a similar change of colour takes place when it is treated successively by dilute hydrocyanic acid and solution of sulphate of copper.

Guaiacin is a name which has been given to the pure resinoid principle of guaiac. It is insoluble in water, but is dissolved readily by alcohol, and less readily by ether. It has the acid property of combining with the alkalies, forming soluble compounds, which are decomposed by the mineral acids and by several salts. Hence it has been called *guaiacic acid*, though this name has also been appropriated to another substance. (See page 360.) It differs from most of the resins in being converted by nitric acid into oxalic acid instead of artificial tannin. It is also peculiar in the changes of colour which it undergoes under the influence of various reagents, and which have been already mentioned. By nitric acid and chlorine it is made to assume successively a green, blue, and brown colour. These changes are ascribed by Mr. Brande to the absorption of oxygen, which forms variously coloured compounds according to the quantity absorbed. Unverdorben considers guaiacin as composed of two resins, one perfectly dissolved by solution of ammonia, the other forming with the alkali a tar-like compound.

It will be inferred from what has been said, that the mineral acids are incompatible with the solutions of guaiac.

This drug is sometimes adulterated with the resin of the pine. The fraud may be detected by the terebinthinate odour exhaled when the sophisticated guaiac is thrown upon burning coals, as well as by its partial solubility in hot oil of turpentine. This liquid dissolves resin, but leaves pure guaiac untouched. Amber is said to be another adulteration. Nitric acid affords an excellent test of guaiac. If paper moistened with the tincture be exposed to the fumes of this acid, it speedily becomes blue.

Medical Properties and Uses. Guaiac is stimulant and alterative, producing, when swallowed, a sense of warmth in the stomach, with dryness of the mouth and thirst, and promoting various secretions. If given to a patient when covered warm in bed, especially if accompanied with opium and ipecacuanha or the antimonials, and assisted by warm drinks, it often excites profuse perspiration; and hence has been usually ranked among the diaphoretics. If the patient be kept cool during its administration, it is sometimes directed to the kidneys, the action of which it promotes. In large doses it purges; and it is thought by some practitioners to be possessed of emmenagogue powers. The complaint in which it has been found most beneficial is rheumatism. In the declining stages of the acute form of this disease, after due depletion, it is very often given in combination with opium, ipecacuanha, nitre, and the antimonials; and in the chronic form is frequently useful without accompaniment. It is also advantageously prescribed in gouty affections; and is occasionally used in secondary syphilis, scrofulous diseases, and cutaneous eruptions, though the guaiacum wood is more frequently resorted to in these latter complaints. It was much relied upon by the late Dr. Dewees in the cure of amenorrhœa and dysmenorrhœa.

The medicine is given in substance or tincture. The dose of the powder is from ten to thirty grains, which may be exhibited in pill or bolus, or in the shape of an emulsion formed with gum Arabic, sugar, and water. An objection to the form of powder is that it quickly aggregates. Guaiac is sometimes administered in combination with alkalies, with which it readily unites. Several of the European Pharmacopœias direct a soap of guaiac, under the name of *sapo guaiacinus*, to be prepared by diluting the Liquor Potassæ with twice its weight of water, boiling lightly, then adding guaiac gradually, with continued agitation, so long as it continues to be dissolved, and finally filtering, and evaporating to the pilular consistence. Of this preparation one scruple may be taken daily in divided doses.

HÆMATOXYLON. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Fabacæ or Leguminosæ.

Gen. Ch. Calyx five-parted. Petals five. Capsule lanceolate, one-celled, two-valved, with the valves boat-form. *Willd.*

Hæmatoxylon Campechianum. Willd. *Sp. Plant.* ii. 547; Woodv. *Med. Bot.* p. 455. t. 163. This is a tree of middle size, usually not more than twenty-four feet high, though under favourable circumstances it sometimes attains an elevation of forty or fifty feet. The trunk, which seldom exceeds twenty inches in diameter, is often very crooked, and is covered with a dark rough bark. The branches are also crooked, with numerous smaller ramifications, which are beset with sharp spines. The sap-wood is yellowish; but the interior layers are of a deep red colour. The leaves are alternate, abruptly pinnate, and composed of three or four pairs of sessile, nearly orbiculate, obliquely nerved leaflets. The flowers, which are in axillary spikes or racemes near the ends of the branches, have a brownish-purple calyx, and lemon-yellow petals. They exhale an agreeable odour, said to resemble that of the jonquil.

The tree is a native of Campeachy, the shores of Honduras Bay, and other parts of tropical America; and has been introduced into Jamaica, where it has become naturalized. The wood, which is the part used in medicine, is a valuable article of commerce, and largely employed in dyeing. It comes to us in logs, deprived of the sapwood, and having a blackish-brown colour externally. For medical use it is cut into chips, or rasped into coarse powder, and in these states is kept in the shops.

Properties. Logwood is hard, compact, heavy, of a deep red colour becoming dark by exposure, of a slight peculiar odour, and a sweet somewhat astringent taste. It imparts its colour to water and to alcohol. The infusion made with cold water, though red, is less so than that with boiling water. It affords precipitates with sulphuric, nitric, muriatic, and acetic acids, with alum, sulphate of copper, acetate of lead, and sulphate of iron, striking a bluish-black colour with the last-mentioned salt. (*Thomson's Dispensatory.*) Precipitates are also produced with it by lime-water and gelatin. Among the constituents of logwood, according to Chevreul, are a volatile oil, an oleaginous or resinous matter, a brown substance the solution of which is precipitated by gelatin (*tannin*), another brown substance soluble in alcohol but insoluble in water or ether, an azotized substance resembling gluten, free acetic acid, various saline matters, and a peculiar azotized principle, called *hematin*, on which the colouring properties of the wood depend. This is obtained by digesting the aqueous extract in alcohol, evaporating the tincture till it becomes thick, then adding a little water, and submitting the liquid to a new but gentle evaporation. Upon allowing it to rest, hematin is deposited in the state of crystals, which may be purified by washing with alcohol and drying. They are shining, of a yellowish rose colour, bitterish, acrid, and slightly astringent to the taste, readily soluble in boiling water, forming an orange-red solution which becomes yellow on cooling, and soluble also in alcohol and ether. Acids added gradually to the solution render it at first yellow and afterwards red. Alkalies render it purple-red, but in great excess produce a violet-blue colour. Hematin unites with various metallic oxides, forming bluish compounds, and yields a flocculent reddish precipitate with a strong solution of glue. It is sometimes found in distinct crystals in the crevices of the wood.

Medical Properties and Uses. Logwood is a mild astringent, devoid of irritating properties, and well adapted to the treatment of that relaxed condition of bowels which is apt to succeed cholera infantum. In this disease it is much used in the United States, and is occasionally employed with advantage in ordinary chronic diarrhœa, and in chronic dysentery. It may be given in decoction or extract, both of which are official.

W.

HEDEOMA. U.S.

Pennyroyal.

"Hedeoma pulegioides." U. S.

This herb, first attached to the genus *Melissa*, and afterwards to *Cunila*, is at present universally considered by botanists as belonging to the *Hedeoma* of Persoon. It has been very erroneously confounded by some with the *Mentha Pulegium*, or European pennyroyal.

HEDEOMA. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Lamiaceæ or Labiatae.

Gen. Ch. Calyx bilabiate, gibbous at the base, upper lip three toothed, lower two; dentures all subulate. Corolla ringent. Stamens, two sterile; the two fertile stamens about the length of the corolla. *Nuttall.*

Hedeoma pulegioides. Barton, *Med. Bot.* ii. 165.—*Cunila pulegioides.* Vahl. *Sp. Plant.* i. 122. This is an indigenous annual plant, from nine to fifteen inches high, with a small, branching, fibrous, yellowish root, and a pubescent stem, which sends off numerous slender erect branches. The leaves are opposite, oblong lanceolate or oval, nearly acute, attenuated at the base, remotely serrate, rough or pubescent, and prominently veined on the under surface. The flowers are very small, of a pale blue colour, supported on short peduncles, and arranged in axillary whorls, along the whole length of the branches.

The plant is common in all parts of the United States, preferring dry grounds and pastures, and, where it is abundant, scenting the air for a considerable distance with its grateful odour.

Both in the recent and dried state it has a pleasant aromatic smell, and a warm, pungent, mint-like taste. It readily imparts its virtues to boiling water. The volatile oil upon which they depend may be separated by distillation, and employed instead of the herb itself.

Medical Properties and Uses. Pennyroyal is a gently stimulant aromatic, and may be given in flatulent colic and sick stomach, or to qualify the action of other medicines. Like most of the aromatic herbs, it possesses the property, when administered in warm infusion, of promoting perspiration, and exciting the menstrual flux when the system is predisposed to the effort. Hence it is much used as an emmenagogue in popular practice, and frequently with success. A large draught of the warm tea is given at bed-time, in recent cases of suppression of the menses, the feet having been previously bathed in warm water.

HELLEBORUS. U.S., Lond., Ed.

Black Hellebore.

"The root of Helleborus niger." U. S., Ed. "Helleborus officinalis. Radix." Lond.

Off. Syn. HELLEBORUS NIGER. Radix. Dub.

Ellebore noire, Fr.; Schwarze Niesswurzel, Germ.; Elleboro nero, Ital.; Heleboro negro, Span.

HELLEBORUS. *Sex. Syst.* Polyandria Polygynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. Calyx none. Petals five or more. Nectaries bilabiate, tubular. Capsules many-seeded, nearly erect. Willd.

Helleborus niger. Willd. *Sp. Plant.* ii. 1336; Woodv. *Med. Bot.* p. 473. t. 169. The root or rhizoma of the black hellebore is perennial, knotted, blackish on the outside, white within, and sends off numerous long, simple, depending fibres, which are brownish-yellow when fresh, but become dark brown upon drying. The leaves are pedate, of a deep green colour, and stand on long footstalks which spring immediately from the root. Each leaf is composed of five or more leaflets, one terminal, and two, three, or four on each side supported on a single partial petiole. The leaflets are ovate lanceolate, smooth, shining, coriaceous, and serrated in their upper portion. The flower-stem, which also rises from the root, is six or eight inches high, round, tapering, reddish towards the base, and bears one or two large, pendent, rose-like flowers, accompanied with floral leaves, which supply the place of the calyx. The petals, five in number, are large, roundish, concave, spreading, and of a white or pale rose colour, with occasionally a greenish tinge. There are two varieties of the plant—the *Helleborus niger humilifolius*, and *Helleborus niger altifolius*—in the former of which the leaves are shorter than the flower stem, in the latter longer.

This plant is a native of the mountainous regions of southern and temperate Europe. It is found in Greece, Austria, Italy, Switzerland, France, and Spain. It is cultivated in gardens for the beauty of its flowers, which expand in the middle of winter, and have, from this circumstance, given rise to the name of *Christmas rose*, by which the black hellebore is sometimes called.

Till the publication of Tournefort's travels in the Levant, this species of hellebore was regarded as identical with that so well known, under the same title, to the ancient Greeks and Romans. But in the island of Anticyra, and various parts of continental Greece, in which it appears from the testimony of ancient writers that the hellebore abounded, this traveller discovered a species entirely distinct from those before described, and particularly from the *H. niger*. He called it *H. orientalis*, and reasonably inferred that it was the true hellebore of the ancients; and botanists at present generally coincide in this opinion. But as the *H. niger* is also found in some parts of Greece, it is not impossible that the two species were indiscriminately employed. It is, indeed, highly probable that they possess similar properties; and a third—the *H. viridis*—which grows in the west of Europe, is said to be frequently substituted for the *H. niger*, which it closely resembles, if it does not equal in medicinal power. The London College has adopted *H. orientalis*, under Salisbury's name of *H. officinalis*. The roots of various other plants not belonging to the same genus are said to be frequently substituted for the black hellebore. They may usually be readily distinguished by attending to the characters of the genuine root.*

* The following minute description of the root, which we copy from Geiger's *Handbuch der Pharmacie*, may perhaps be useful in enabling the druggist to distinguish this from other analogous roots mingled with or substituted for it in commerce. "It is usually a many-headed root, with a caudex or body half an inch thick or less, seldom thicker, and several inches long, horizontal, sometimes variously contorted, uneven, knotty, with transverse ridges, slightly striated longitudinally, presenting on its upper surface the short remains of the leaf and flower-stalks, and thickly beset upon the sides and under surface with fibres of the thickness of a straw, and from six to twelve inches long. These are undivided above, but at the distance of from two to six inches from their origin, are furnished with small, slender branches. The colour of the root is dark-brown, sometimes rather light-brown, dull, and for the most part exhibiting a gray, earthy tinge. Inter

The medicine of which we are treating is sometimes called *melampodium*, in honour of Melampus, an ancient shepherd or physician, who is said to have cured the daughters of king Prætus by giving them the milk of goats which had been fed on hellebore.

Properties. Though the whole root is kept in the shops, the fibres are the portion usually recommended. They are about as thick as a straw, when not broken from four inches to a foot in length, smooth, brittle, externally black or deep brown, internally white or yellowish-white, with little smell, and a bitterish, nauseous, acrid taste. In their recent state they are extremely acrimonious, producing on the tongue a burning and benumbing impression like that which results from taking hot liquids into the mouth. This acrimony is diminished by drying, and still further impaired by age. MM. Feneulle and Capron obtained from black hellebore, a volatile oil, an acrid fixed oil, a resinous substance, wax, a volatile acid, bitter extractive, gum, albumen, gallate of potassa, supergallate of lime, a salt of ammonia, and woody fibre. Water and alcohol extract its virtues, which are impaired by long boiling.

Medical Properties and Uses. Black hellebore is a drastic hydragogue cathartic, possessed also of emmenagogue powers, which by some are ascribed to a specific tendency to the uterus, by others are supposed to depend solely on the purgative property. In overdoses it produces inflammation of the gastric and intestinal mucous membrane, with violent vomiting, hypercatharsis, vertigo, cramp, and convulsions, which sometimes end in death. The fresh root applied to the skin produces inflammation and even vesication. The medicine was very highly esteemed by the ancients, who employed it in mania, melancholy, amenorrhœa, dropsy, epilepsy, various cutaneous affections, and verminous diseases. By the earlier modern physicians it was also much used. *Bacher's pills*, celebrated for the cure of dropsy, consisted chiefly of black hellebore. It is at present little employed, except as an emmenagogue, in which capacity it is very highly esteemed by some practitioners. Dr. Mead considered it superior to all other medicines belonging to this class. It may be given in substance, extract, decoction, or tincture. The dose of the powdered root is from ten to twenty grains as a drastic purge, two or three grains as an alterative. The decoction is prepared by boiling two drachms in a pint of water, of which a fluidounce may be given every four hours till it operates. The extract and tincture are officinal.

HEPATICA. *U. S. Secondary.*

Liverwort.

“The leaves of *Hepatica Americana.*” *U. S.*

HEPATICA. Sex. Syst. Polyandria Polygynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. Calyx three-leaved. Petals six to nine. Seeds naked. *Nuttall.*

nally it is whitish, with a somewhat darker pith, which, when cut transversely, shows lighter converging rays. Sometimes it is porous. It has a medullary or fleshy, not a ligneous consistence. The fibres, when dried, are wrinkled, very brittle, sometimes grayish internally, horny, with a white point in the centre. The odour of the dried root is feeble, somewhat like that of seneca, but more nauseous, especially when the root is rubbed with water. The taste is at first sweetish, then nauseously acrid and biting, but not very durable, and slightly bitterish.” *Band. ii. s. 1181.*

Hepatica Americana. De Cand.; Eaton, *Man. of Bot.* p. 241.—*H. triloba*. Willd. *Enum.*; Figured in Rafinesque's *Med. Flor.* i. 238. Botanists generally admit but one species of *Hepatica*, the *H. triloba*, and consider as accidental the differences of structure and colour observable in the plant. Pursh speaks of two varieties, one with the lobes of the leaf oval and acute, the other with the lobes rounded and obtuse. These are considered as distinct species by De Candolle, and the latter is the one which has been adopted by the Pharmacopœia, and is popularly employed as a medicine in this country, under the name of *liverwort*. Both have a perennial fibrous root, with three-lobed leaves, cordate at their base, coriaceous, nearly smooth, glaucous and purplish beneath, and supported upon hairy footstalks from four to eight inches long, which spring directly from the root. The scapes or flower-stems are several in number, of the same length with the petioles, round, hairy, and terminating in a single white, bluish, or purplish flower. The calyx is at a little distance below the corolla, and is considered by some an involucre, while the corolla takes the name of the calyx. In the *H. acutiloba* the leaves are cordate, with from three to five entire, acute lobes; and the leaflets of the calyx are acute. In the *H. Americana* the leaves are cordate-reniform, with three entire, roundish, obtuse lobes; and the leaflets of the calyx are obtuse. Both are indigenous, growing in woods upon the sides of hills and mountains; the former, according to Eaton, preferring the northern, the latter the southern exposure. The leaves resist the cold of the winter, and the flowers make their appearance early in spring. The whole plant is used.

It is without smell, and has a mucilaginous, somewhat astringent, slightly bitterish taste. Water extracts all its active properties.

Medical Properties and Uses. Liverwort is a very mild, demulcent tonic and astringent, supposed by some to possess diuretic and deobstruent virtues. It was formerly used to some extent in Europe in various complaints, especially in chronic hepatic affections; but has fallen into entire neglect. In this country, some years since, it attracted much attention as a remedy in hæmoptysis and chronic coughs, and acquired for a time great popular confidence. Its credit, however, has declined. It may be used in infusion and taken ad libitum. The term *liverwort* properly belongs to the cryptogamous genus *Marchantia*. W.

HERACLEUM. U.S. Secondary.

Masterwort.

“The root of *Heracleum lanatum*.” U.S.

HERACLEUM. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Apiaceæ or Umbelliferae.

Gen. Ch. *Fruit* elliptical, emarginate, compressed, striated, margined. *Corolla* difform, inflexed, emarginate. *Involucre* caducous. *Willd.*

Heracleum lanatum. Michaux, *Flor. Boreal. Am.* i. 166. This is one of our largest indigenous umbelliferous plants. The root is perennial, sending up annually a hollow pubescent stem, from three to five feet high, and often more than an inch in thickness. The leaves are ternate, downy on their under surface, and supported on downy footstalks; the leaflets petiolate, roundish, cordate, and lobed. The flowers are white, in large umbels, and followed by orbicular seeds.

Like the European species this is sometimes called cow-parsnip. It

grows in meadows and along fences or hedges, from Canada to Pennsylvania, and flowers in June.

The root, which is the officinal part, bears some resemblance to that of common parsley in appearance. It has a strong disagreeable odour, and a very acrid taste. Both the leaves and root excite redness and inflammation when applied to the skin. Dr. Bigelow considers the plant poisonous, and advises caution in its use, especially when it is gathered from a damp situation.

Medical Properties, &c. Masterwort appears to be somewhat stimulant and carminative, and was used successfully by Dr. Orne, of Salem, Massachusetts, in cases of epilepsy, attended with flatulence and gastric disorder. He directed two or three drachms of the pulverized root to be taken daily, for a long time, and a strong infusion of the leaves to be drunk at bed-time. (*Thacher's Dispensatory.*) W.

HEUCHERA. U.S. Secondary.

Alum-root.

“The root of *Heuchera Americana*.” U. S.

HEUCHERA. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Saxifragaceæ.

Gen. Ch. Calyx five-cleft. Petals five, small. Capsule bi-rostrate, bi-locular, many-seeded. *Nuttall.*

Heuchera Americana. Willd. *Sp. Plant.* i. 1328; Barton, *Med. Bot.* ii. 159.—*H. cortusa.* Michaux, *Flor. Boreal. Am.* i. 171.—*H. viscida.* Pursh, *Flor. Am. Sept.* p. 187. The *alum-root* or *American sanicle* is a perennial, herbaceous plant, the leaves of which are all radical, petiolate, cordate, with rounded lobes, furnished with obtuse mucronate teeth. There is no proper stem; but numerous scapes or flower-stems are sent up by the same root, from one to three feet in height, very hairy in their upper part, and terminating in long, loose, pyramidal, dichotomous panicles. The calyx is small, with obtuse segments; the petals lanceolate, rose-coloured, and of the same length with the calyx; the filaments much longer, yellowish, and surmounted by small, red, globose anthers. The whole plant is covered with a viscid pubescence.

It is found in shady, rocky situations, from New England to Carolina, and flowers in June and July. The root is the medicinal portion. It is horizontal, somewhat compressed, knotty, irregular, yellowish, and of a strongly styptic taste.

Medical Properties. Alum-root is powerfully astringent, and may be employed in similar cases with other medicines belonging to the same class. It has hitherto, however, been little used. We are informed in Dr. Barton's “Collections,” that it is applied by the Indians to wounds and obstinate ulcers, and that it is the basis of a powder which, when the author wrote, enjoyed some reputation as a cure for cancer. W.

HIRUDO. Lond.

The Leech.

Off. Syn. HIRUDO MEDICINALIS. *Dub.*

Sangsue, *Fr.*; Bluteegel, *Germ.*; Mignatta, *Ital.*; Sauguijuela, *Span.*

HIRUDO. *Class* 1, Annelides. *Order* 3, Abranchiatæ. *Family* 2, Asetigeræ. *Cuvier.*

The leech belongs to that class of invertebrated articulated animals called *Annelides*. This class contains the worms with red blood, having soft retractile bodies composed of numerous segments or rings, breathing generally by means of branchiæ, with a nervous system consisting in a double knotted cord, destitute of feet, and supplying their place by the contractile power of their segments or rings. The third order of this class—*Abranchiatæ*—comprehends those worms which have no apparent external organ of respiration. This order is again divided into two families, to the second of which—the *Asetigeræ*, or those not having setæ to enable them to crawl—the leech belongs.

It is an aquatic worm with a flattened body, tapering towards each end, and terminating in circular flattened disks, the hinder one being the larger of the two. It swims with a vertical undulating motion, and moves when out of the water by means of these disks or suckers, fastening itself first by one and then by the other, and alternately stretching out and contracting its body. The mouth is placed in the centre of the anterior disk, and is furnished with three cartilaginous lens-shaped jaws at the entrance of the alimentary canal. These jaws are lined at their edges with fine sharp teeth, and meet so as to make a triangular incision in the flesh. The head is furnished with small raised points, supposed by some to be eyes. Respiration is carried on through small apertures ranged along the inferior surface. The nervous system consists of a cord extending the whole length, furnished with numerous ganglions. The intestinal canal is straight and terminates in the anus, near the posterior disk. Although hermaphrodite, leeches mutually impregnate each other. They are oviparous, and the eggs, varying from six to fifteen, are contained in a sort of spongy, slimy cocoon, from half an inch to an inch in diameter. These are deposited near the edge of the water, and hatched by the heat of the sun. The leech is torpid during the winter, and casts off from time to time a thick slimy coating from its skin. It can live a considerable time in sphagnous moss, or in moistened earth, and is frequently transported in this manner to great distances by the dealers.

Savigny has divided the genus *Hirudo* of Linnæus into several genera. The true leech is the *Sanguisuga* of this author, and is characterized by its three lenticular jaws, each armed with two rows of teeth, and by having ten ocular points.

Several species are used for medicinal purposes, of which the most common are the gray and the green leech of Europe, both of which are varieties of the *Hirudo medicinalis* of Linnæus; and the *Hirudo decora* of this country.

1. *Hirudo medicinalis*, Linn. *Ed. Gmel.* I. 3095.—*Sanguisuga officinalis*. Savigny, *Mon. Hir.* p. 112. t. 5. f. 1. *The green leech.*—*Sanguisuga medicinalis*. Savigny, *Mon. Hir.* p. 114, t. 5. f. 2. *The gray leech.* Many of the best zoologists regard the *Sanguisuga officinalis* and *S. medicinalis* of Savigny as mere varieties. They are both marked with six longitudinal dorsal ferruginous stripes, the four lateral ones being interrupted or tessellated with black spots. The colour of the back varies from a blackish to a grayish-green. The belly in the first variety is of a yellowish-green colour, free from spots, and bordered with longitudinal black stripes. In the second it is of a green colour, bordered and maculated with black. This leech varies from two to three or four inches in length. It inhabits marshes and running streams, and is found abundantly throughout Europe.

The great use made of leeches in the modern practice of medicine has occasioned them to become a considerable article of commerce. They are collected in Spain, France, Italy, and Germany, and carried in large numbers

to London and Paris. They are also frequently brought to this country; as the practitioners in some of our large cities use only the foreign leech, although our own waters furnish an inexhaustible supply of this useful worm.

2. *Hirudo decora*. Say, *Major Long's Second Expedition*, ii. 268. The medicinal leech of America has been described by Say under the name of *Hirudo decora*, in the Appendix to the Second Expedition of Major Long. Its back is of a deep pistachio green colour, with three longitudinal rows of square spots. These spots are placed on every fifth ring, and are twenty-two in number. The lateral rows of spots are black, and the middle range of a light brownish-orange colour. The belly is of the same colour, variously and irregularly spotted with black. The American leech sometimes attains the length of four or five inches, although its usual length is from two to three. It does not make so large and deep an incision as the European leech, and draws less blood.

The use of the indigenous leech is nearly restricted to the city of Philadelphia. The practitioners of New York and Boston depend for their supplies upon foreign countries, and leeching is seldom resorted to in the southern or western states. Those which are used in Philadelphia are generally brought from Bucks and Berks county in Pennsylvania, and occasionally from other parts of the State. It is estimated that from 200,000 to 250,000 are annually consumed.

The proper preservation of leeches is an object of importance to the practitioner, as they are liable to great and sudden mortality. They are usually kept in jars in clear water, which should be changed twice or three times a week. The jar must be covered with a linen cloth, and placed in a situation not liable to sudden changes of temperature. They will live a long time, and continue active and healthy, without any other attention than that of frequently changing the water in which they are kept. M. Derheims has proposed the following excellent method of preserving them. In the bottom of a large basin or trough of marble he places a bed, six or seven inches deep, of a mixture of moss, turf, and fragments of wood. He strews pebbles above, so as to retain them in their place without compressing them too much, or preventing the water from freely penetrating them. At one end of the trough, and about mid-way of its height, is placed a thin slab of marble or earthenware, pierced with numerous holes and covered with a bed of moss, which is compressed by a thick layer of pebbles. The reservoir being thus disposed is half filled with water, so that the moss and pebbles on the shelf shall be kept constantly moist. The basin is protected from the light by a linen cover stretched over it. By this arrangement the natural habits of the leech are not counteracted. One of these habits, essential to its health, is that of drawing itself through the moss and roots to clear its body from the slimy coat which forms on its skin, and is a principal cause of its disease and death.

Medical Uses.—Leeches afford the least painful, and in many instances the most effectual means for the local abstraction of blood. They are often applicable to parts which, either from their situation, or their great tenderness when inflamed, do not admit of the use of cups; and in the cases of infants, are, under all circumstances, preferable to this instrument. They are indeed a powerful therapeutic agent, and give to the physician in many instances, a control over disease which he could obtain in no other way. Their use is in great measure restricted to the treatment of local inflammations; and, as a general rule, they should not be resorted to until the force of the circulation has been diminished by bleeding from the arm, or in the natural progress of the complaint.

In applying leeches to the skin, care should be taken to shave off the hair, if there be any, and to have the part well cleansed with soap and water, and afterwards with pure water. If the leech does not bite readily, the skin should be moistened with a little blood, or milk and water. Sometimes the leech is put into a large quill open at both ends, and applied with the head to the skin until it fastens itself, when the quill is withdrawn. If it be desirable that the leech shall bite in a particular spot, this end may be attained by cutting a small hole in a piece of blotting paper, and then applying this moistened to the skin, so that the hole shall be immediately over the spot from which the blood is to be taken. Leeches continue to draw blood until they are gorged, when they drop off. The quantity of blood which they draw varies according to the part to which they are applied, and the degree of inflammation existing in it. In the loose and vascular textures they will abstract more than in those which are firm and compact, and more from an inflamed than a healthy part. As a general rule, our leechers apply six for every fluidounce of blood. A single European leech will draw from half an ounce to an ounce. The quantity may often be much increased by bathing the wound with warm water. Leeches will continue to suck after their tails are cut off, which is sometimes done, although it is a barbarous practice. They may be separated from the skin at any time by sprinkling a little salt upon them. After they drop off the same application will make them disgorge the blood they have swallowed. Some leechers draw the leeches from the tail to the head through their fingers, and thus squeeze out the blood, after which all that is necessary is to put them in clean water and change it frequently. Leeches which are gorged with blood should be kept in a vessel by themselves, as they are more subject to disease, and often occasion a great mortality among the others. They should not be again used until they have recovered their activity.

In cases where the bleeding from leech-bites continues longer than is desirable, it may be stopped by continued pressure, with the application of lint, or by touching the wounds with lunar caustic.* It may sometimes be necessary, in the case of a deep bite, to sew the wound, which is readily done with a single stitch of the needle that need not penetrate deeper than the cutis.

HORDEUM. Sex. Syst. Triandria Digynia.—Nat. Ord. Graminaceæ.

Gen. Ch. *Calyx* lateral, two-valved, one flowered, three-fold. Willd.

Several species of *Hordeum* are cultivated in different parts of the world. The most common are the *H. vulgare*, and *H. distichon*, both of which have been introduced into the United States.

1. *Hordeum vulgare*. Willd. *Sp. Plant.* i. 472; Loudon's *Encyc. of Plants*, p. 73. The culm or stalk of common barley is from two to four feet in height, fistular, and furnished with alternate, sheathing, lanceolate,

* A little cotton, impregnated with a saturated solution of alum, will sometimes be found an effectual application.

roughish, and pointed leaves. The flowers are all perfect, and arranged in a close terminal spike, the axis of which is dentate, and on each tooth supports three sessile flowers. The calyx or outer chaff has two valves. The corolla or inner chaff is also composed of two valves, of which the exterior is larger than the other, and terminates in a long, rough, serrated awn or beard. The seeds are arranged in four rows.

2. *H. distichon*. Willd. *Sp. Plant.* i. 473; Loudon's *Encyc. of Plants*, p. 73. This species is distinguished by its flat spike or ear, which on each flat side has a double row of imperfect or male florets without beards, and on each edge, a single row of bearded perfect or hermaphrodite florets. The seeds therefore are in two rows, as indicated by the specific name of the plant.

The original country of the cultivated barley is unknown. The plant has been found growing wild in Sicily, and various parts of the interior of Asia; but it may have been introduced into these places. The *H. vulgare* is said by Pursh to grow in some parts of the United States, apparently in a wild state. The seeds are used in various forms.

1. In their natural state they are oval, oblong, pointed at one end, obtuse at the other, marked with a longitudinal furrow, of a yellowish colour externally, white within, having a faint odour when in mass, and a mild sweetish taste. They contain, according to Proust, in 100 parts, 32 of starch, 3 of gluten, 5 of sugar, 4 of gum, 1 of yellow resin, and 55 of *hordein*, a principle closely analogous to lignin. Berzelius suggests that hordein may be an intimate mixture of vegetable fibre with gluten and starch, which are very difficultly separable as they exist in this grain. Einhoff found in 100 parts, 67.18 of starch, 5.21 of uncrystallizable sugar, 4.62 of gum, 3.52 of gluten, 1.15 of albumen, 0.24 of phosphate of lime, and 7.29 of vegetable fibre; the remainder being water and loss.

2. *Malt* consists of the seeds made to germinate by warmth and moisture, and then baked so as to deprive them of vitality. By this process the sugar, starch, and gum are increased at the expense of the *hordein*, as shown by the analysis of Proust, who found in 100 parts of malt, 56 of starch, 1 of gluten, 15 of sugar, 15 of gum, 1 of yellow resin, and only 12 of *hordein*. Berzelius attributes the diminution of the hordein to the separation, during germination, of the gluten or starch from the fibrous matter with which he supposes them to be associated in that substance. It is in the form of malt that barley is so largely consumed in the manufacture of malt liquors.

An interesting substance called *diastase* has been discovered by MM. Payen and Persoz in the seeds of barley, oats, and wheat, and in the potato. It is found, however, only after these have undergone germination, of which process it appears to be a product. Germinated barley seldom contains it in larger proportion than two parts in a thousand. It is obtained by bruising freshly germinated barley, adding about half its weight of water, expressing strongly, treating the viscid liquid thus obtained with sufficient alcohol to destroy its viscosity, then separating the coagulated albumen, and adding a fresh portion of alcohol, which precipitates the diastase in an impure state. To render it pure, it must be redissolved as often as three times in water, and precipitated by alcohol. It is solid, white, tasteless, soluble in water and weak alcohol, but insoluble in the latter fluid in a concentrated state. Though without action upon gum and sugar, it has the extraordinary property, when mixed, in the proportion of only one part to 2000, with starch suspended in water, and maintained at a temperature of about 160°, of converting this principle into dextrine and the sugar of grapes. The

whole of the starch undergoes this change, with the exception of the teguments of the granules, amounting to about 4 parts in 1000.

3. *Hulled barley* is merely the grain deprived of its husk, which, according to Einhoff, amounts to 18·75 parts in the hundred.

4. *Barley meal* is formed by grinding the seeds previously deprived of their husk. It has a grayish-white colour, and contains, according to Fourcroy and Vauquelin, an oleaginous substance, sugar, starch, azotized matter, acetic acid, phosphate of lime and magnesia, silica, and iron. It may be made into a coarse, heavy, hard bread, which in some countries is much used for food.

5. *Pearl barley—hordeum perlatum*—is the seed deprived of all its investments, and afterwards rounded and polished in a mill. It is in small round or oval grains, having the remains of the longitudinal furrow of the seeds, and of a pearly whiteness. It is wholly destitute of hordein, and abounds in starch, with some gluten, sugar, and gum. This is the proper officinal form of barley, and is kept in the shops almost to the exclusion of the others.

Medical Properties. Barley is one of the mildest and least irritating of farinaceous substances; and, though not medically used in its solid state, forms by decoction with water a drink admirably adapted to febrile and inflammatory complaints, and much employed from the times of Hippocrates and Galen to the present. Pearl barley is the form usually preferred for the preparation of the decoction, though the hulled grain is sometimes used, and malt affords a liquor more demulcent and nutritious, and therefore better adapted to cases of disease which require a supporting treatment. (See *Decoctum Hordei*.) The decoction of malt may be prepared by boiling from two to four ounces in a quart of water and straining the liquor. When hops are added, the decoction takes the name of wort, and acquires tonic properties, which render it useful in debilitated conditions of the system, especially those which attend the suppurative process.

Humulus Lupulus. Willd. *Sp. Plant.* iv. 769; Bigelow, *Am. Med. Bot.* iii. 163. The root of the hop is perennial, and sends up numerous annual angular, rough, flexible stems, which twine around neighbouring objects in a spiral direction, from left to right, and climb to a great height. The leaves are opposite, and stand upon long footstalks. The smaller are sometimes cordate; the larger have three or five lobes; all are serrate, of a deep green colour on the upper surface, and, together with the petioles, extremely rough, with minute prickles. At the base of the footstalks are two or four smooth,

ovate, reflexed stipules. The flowers are numerous, axillary, and furnished with bracts. The male flowers are yellowish-white, and arranged in panicles; the female, which grow on a separate plant, are pale green, and disposed in solitary, peduncled aments, composed of membranous scales, ovate, acute, and tubular at the base. Each scale bears near its base, on its inner surface, two flowers, consisting of a roundish compressed germ, and two styles, with long filiform stigmas. The aments are converted into ovate membranous cones or strobiles, the scales of which contain each at their base two small seeds, surrounded by a yellow, granular, resinous powder.

The hop is a native of North America and Europe. It is occasionally found growing wild in the Eastern States, and, according to Mr. Nuttall, is abundant on the banks of the Mississippi and Missouri. In New England it is extensively cultivated, and most of the hops consumed in the United States, are supplied by that district of country. The part of the plant used, as well in the preparation of malt liquors as in medicine, is the fruit or strobiles. These when fully ripe are picked from the plant, dried by artificial heat, packed in bales, and sent into the market, under the name of hops.

They consist of numerous thin, translucent, veined, leaf-like scales, which are of a pale greenish-yellow colour, and contain near their base two small, round, black seeds. Though brittle when quite dry, they are pulverized with great difficulty. Their odour is strong, peculiar, somewhat narcotic, and fragrant; their taste very bitter, aromatic, and slightly astringent. Their aroma, bitterness, and astringency are imparted to water by decoction; but the first mentioned property is dissipated by long boiling. The most active part of hops is a substance secreted by the scales, and in the dried fruit existing upon their surface in the form of a powder composed of very small granules. This substance was called *lupulin* by the late Dr. A. W. Ives, of New York, by whom its properties were first investigated, and made generally known; though it appears to have been previously noticed by Sir J. E. Smith of England, and M. Planche of France. It enters into the officinal catalogue of the United States Pharmacopœia. The scales themselves, however, are not destitute of virtues, and contain, as shown by MM. Payen and Chevallier, the same active principles as the powder upon their surface, though in smaller proportion.

LUPULINA. *Lupulin.* *U. S.* This is obtained separate by rubbing or threshing and sifting the strobiles, of which it constitutes from one-sixth to one-tenth by weight. It is in the state of a yellowish powder, mixed with minute particles of the scales, from which it cannot be entirely freed when procured by a mechanical process. It has the peculiar flavour of hops, and appeared to MM. Lebaillif and Raspail, when examined by the microscope, to consist of globules filled with a yellow matter, resembling in this respect the pollen of vegetables. It is inflammable, and when moderately heated becomes somewhat adhesive. MM. Chevallier and Payen obtained from 200 parts, 105 of resin, and 25 of a peculiar bitter principle, besides volatile oil, gum, traces of fixed oil, a small quantity of an azotized substance, and various salts. Dr. Ives found in 120 grains, 5 of tannin, 10 of extractive, 11 of bitter principle, 12 of wax, 36 of resin, and 46 of lignin. The virtues of the powder probably reside in the volatile oil and bitter principle, and are readily imparted to alcohol. By boiling in water the bitterness is extracted, but the aroma is partially driven off. The *volatile oil*, which may be obtained by distillation with water, is yellowish, of the odour of hops, of an acrid taste, and lighter than water. It is said to have narcotic properties.

The bitter principle, which is called *lupulite* or *lupuline*, may be procured by treating with alcohol the aqueous extract of lupulin previously mixed

with a little lime, evaporating the tincture thus formed, treating the resulting extract with water, evaporating the solution, and washing the residue with ether. In a state of purity, it is yellowish or orange-yellow, inodorous at common temperatures, but of the smell of hops when heated, of the peculiar bitter taste of hops, slightly soluble in water which takes up five per cent. of its weight, readily soluble in alcohol, almost insoluble in ether, neither acid nor alkaline in its reaction, and without nitrogen in its composition. It is scarcely affected by the weak acids or alkaline solutions, or by the metallic salts. It is probably the tonic principle of the medicine.

Medical Properties and Uses. Hops are tonic and moderately narcotic, and have been highly recommended in diseases of general or local debility, associated with morbid vigilance, or other nervous derangement. They have some tendency to produce sleep and relieve pain, and may be used for these purposes in cases where opiates, from their tendency to constipate, or other cause, are inadmissible. Diuretic properties have also been ascribed to them, but are by no means very obvious. The complaints in which they have been found most useful are dyspepsia, and the nervous tremors, wakefulness, and delirium of drunkards. Dr. Maton found the extract advantageous in allaying the pain of articular rheumatism.

The medicine may be given in substance, infusion, tincture, or extract. From three to twenty grains are mentioned as the dose of the powder; but the quantity is too small to produce any decided effect; and this mode of administration is in fact scarcely ever resorted to. An infusion prepared from half an ounce of hops and a pint of boiling water, may be given in the dose of two fluidounces three or four times a day. The extract and tincture are officinal. (See *Extractum Humuli Lupuli* and *Tinctura Humuli*.) A pillow of hops has been found useful in allaying restlessness and producing sleep, in cases of nervous derangement. They should be moistened with some spirituous liquor previously to being placed under the head of the patient, in order to prevent their rustling noise. Fomentations with hops, and cataplasms made by mixing them with some emollient adhesive substance, are often beneficial in local pains and tumefactions. An ointment of the powder with lard is recommended by Mr. Freake as an application to cancerous sores, the pain of which it has relieved when other means have failed.

All the effects of the preparations of hops may be obtained with greater certainty and convenience by the use of *lupulin*. The dose of this in substance is from six to twelve grains, given in the form of pills, which may be made by simply rubbing the powder in a warm mortar till it acquires the consistence of a ductile mass, and then moulding it into the proper shape. A tincture is directed by the United States Pharmacopœia. (See *Tinctura Lupulinæ*.) Lupulin may be incorporated with poultices, or formed into an ointment with lard, and used externally for the same purposes as the hops themselves.

HYDRARGYRUM. U.S., Lond., Ed., Dub.

Mercury.

Quicksilver; Mercurius, *Lat.*; Mercure, *Vif argent, Fr.*; Quecksilber, *Germ.*; Mercurio, *Ital.*; Azóque, *Span. and Port.*

This metal is found pure, combined with sulphur, united with silver, and in the form of protochloride (native calomel); but of all its combinations, the most abundant is the bisulphuret, or native cinnabar. Its most important mines are found at Almaden in Spain, at Idria in Carniola, in the Duchy of Deux-Ponts, at Durasno in Mexico, near Azogue in New Granada, and near Huancavelica in Peru. It also occurs in the Philippine Islands and China. The most ancient and productive mine is that of Almaden.

Extraction. Nearly all the mercury consumed in medicine and the arts, is obtained from the bisulphuret, or native cinnabar. It is extracted by two principal processes. According to one process the mineral is picked, pounded, and mixed with lime. The mixture is then introduced into cast iron retorts, which are placed in rows, one above the other, in an oblong furnace, and connected with earthenware receivers, one-third full of water. Heat being applied, the lime combines with the sulphur, so as to form sulphuret of calcium and sulphate of lime, while the mercury distils over, and is condensed in the receivers. The other process is practised at Almaden in Spain. Here a square furnace is employed, the floor of which is pierced with many holes, for the passage of the flame from the fireplace underneath. At the upper and lateral part of the furnace, holes are made, which communicate with several rows of *aludels*,* which terminate in a small chamber that serves both as condenser and receiver. The mineral, having been picked by hand and pulverized, is kneaded with clay and formed into small masses which are placed on the floor of the furnace. The heat being applied, the sulphur undergoes combustion, while the mercury, being volatilized, passes through the aludels to be condensed in the chamber. This process economizes fuel, but is wasteful of the mercury.

Commercial History. Mercury is imported into this country generally in cylindrical wrought-iron bottles, called flasks, each containing $76\frac{1}{2}$ pounds, and comes principally from the Atlantic ports of Spain, particularly Cadiz. A portion also is received from the Austrian port of Trieste, from which it generally comes tied up in whole skins of white leather, forming bags, each containing 31 pounds, and four of which are usually packed together with straw in a rough flattened keg. In both Spain and Austria, the produce of the quicksilver mines is a government monopoly. In Spain all the metal is brought from the mines to Seville, whence, after paying an export duty, it is carried by small vessels down the river Guadalquivir to Cadiz and Gibraltar, which are the chief places of its depot for foreign commerce. The quantity imported into the United States varies in different years. Its value for the year ending in Sept. 1832, exceeded two hundred and sixty-three thousand dollars. The greater part received is exported again, principally to Mexico, Chili, and China. Its principal consumption is caused by its employment in the extraction of silver and gold from its ores, and in the preparation of vermilion. In the United States it is consumed for making thermometers and barometers, for silvering looking-glasses, and for pre-

* Aludels are a kind of pot, open at both ends, and which admit of being adjusted to one another, so as to form a sort of tube.

paring various pharmaceutical compounds. Of late the home consumption has increased, in consequence of its employment in the mining operations of the gold region of the Southern States.

Properties. Mercury is a very brilliant liquid, of a silver-white colour, and without taste or smell. When perfectly pure it undergoes no alteration by the action of air or water, but, in its ordinary state, suffers a slight tarnish. When heated to near the boiling point, it gradually combines with oxygen, and becomes converted into deutoxide; but at the temperature of ebullition, it parts with the oxygen which it had absorbed, and is reduced again to the metallic state. Its sp. gr. is 13·5, and its equivalent number 202. Liquid at ordinary temperatures, it freezes at 39° below zero, and boils at 656°. When frozen, it forms a malleable solid resembling lead. It is a good conductor of caloric, and its specific heat is small. It is not attacked by muriatic acid, nor by cold sulphuric acid; but boiling sulphuric acid, or cold nitric acid dissolves it, generating either a sulphate or nitrate of the deutoxide, with the extrication, in the former case, of sulphurous acid, in the latter, of nitric oxide becoming nitrous acid red fumes. Its combinations are numerous, and several of them constitute important medicines. It forms two oxides, two sulphurets, two chlorides, three iodides, and one cyanuret, all of which, excepting the protosulphuret and sesquiodide, are officinal, and will be noticed elsewhere under separate heads. Both the oxides are capable of uniting with acids so as to form salts, of which the nitrate, sulphate, bisulphate, and acetate of the deutoxide are officinal, or enter into officinal combinations.

Mercury, as it occurs in commerce, is generally sufficiently pure for pharmaceutical purposes. Occasionally it contains foreign metals, such as lead, bismuth, and tin. Mr. Brande informs us that in examining large quantities of this metal in the London market, he found it only in one instance intentionally adulterated. When impure, the metal has a dull appearance, easily tarnishes, is deficient in due fluidity and mobility, as shown by its not forming round globules, is not totally dissipated by heat, and when rolled over white paper leaves a trace. If agitated with strong sulphuric acid, the adulterating metals become oxidized, and in this manner the mercury may in part be purified. Lead is detected by shaking the suspected metal with equal parts of acetic acid and water, and then testing the acid by sulphate of soda, or iodide of potassium. The former will produce a white, the latter a yellow precipitate, if lead be present. Bismuth is discovered by dropping a nitric solution of the mercury, prepared without heat, into distilled water, when the subnitrate of bismuth will precipitate. The solubility of the metal in nitric acid shows that tin is not present; and if sulphuretted hydrogen does not act upon muriatic acid previously boiled upon the metal, the absence of most other metals is indicated.

Mercury may be purified, according to Berzelius, by digesting it with a small portion of nitric acid, or with a solution of bichloride of mercury (corrosive sublimate); whereby all the ordinary contaminating metals will be removed. It is, however, usually purified by distillation; and the Dublin College has given directions for conducting the process. (See *Hydrargyrum Purificatum*.)

Medical Properties. Mercury, in its uncombined state, is deemed inert; but in a state of combination, it acts as a peculiar and universal stimulant. When exhibited in a state of minute division, as it exists in several preparations, it produces its peculiar effects; but this does not prove that the uncombined metal is active, but only that the condition of minute division is favourable to its entering into combination in the stomach. Its combina-

tions exhibit certain general medical properties and effects, which belong to the whole as a class; while each individual preparation is characterized by some peculiarity in its operation. Our business, in the present place, is to consider generally the physiological action of mercury, and the principles by which its administration should be regulated; while its effects, as modified in its different combinations, will more properly be noticed under the head of each preparation individually.

Of the *modus operandi* of mercury we know nothing, except that it probably acts through the medium of the circulation, and that it possesses a peculiar alterative power over the vital functions, which enables it in many cases to subvert diseased actions by substituting its own in their stead. This alterative power is sometimes exerted, without being attended with any other vital phenomenon than the removal of the disease, while at other times it is attended with certain obvious effects, indicative of the agency of a potent stimulus. In the latter case, its operation is marked by a quickened circulation, with a frequent, jerking pulse, by an increased activity imparted to all the secretory functions, particularly those of the salivary glands and the liver, by an exaltation of nervous sensibility, and, in short, by a general excitement of the organic actions of the system. When its effects are no otherwise obvious than in the subversion of disease, its operation, though so slight and imperceptible as altogether to escape notice, may be presumed to be the same as when it produces obviously stimulating effects.

When mercury acts insensibly as an alterative, there is not the least apparent disturbance of the circulation; but when it operates decidedly and obviously, it is very prone to let the brunt of its action fall upon the salivary glands, causing, in many instances, an immoderate flow of saliva, and constituting the condition denominated *ptyalism* or salivation. Under these circumstances, to the alterative effects of the mineral are added those of depletion and revulsion. In the saliva, discharged as a consequence of its action, mercury has been detected by chemical tests. (*Journ. de Pharm.* xxiii. 625.) Occasionally its depletory action is exhibited in an increased secretion of urine, or an immoderate flow of the bile; and where *ptyalism* cannot be induced, and either of these secretions becomes considerably augmented, the circumstance may be held as equally conclusive of the constitutional impression of the mercury, as if the mouth had been affected.

Mercury has been used in almost all diseases, but too often empirically, and without the guidance of any recognised therapeutic principle. Nevertheless, its efficacy in certain classes of diseases is universally acknowledged. In functional derangement of the digestive organs, mercurials in minute doses exert a salutary operation, subverting the morbid action, and that too by its insensible alterative effect, without affecting the mouth. In these cases no decided disturbance of the vital functions takes place; but the alvine discharges, if clay-coloured, are generally restored to their natural hue, a certain proof that the remedy is stimulating the liver, and promoting the secretion of the bile. Indeed there is no fact better established in medicine, than that of the influence of the mercurial preparations over the hepatic system; and whether the liver be torpid and obstructed as in jaundice, or pouring out a redundancy of morbid bile as in *melæna*, its judicious use seems equally efficacious in unloading the viscus, and restoring its secretion to a healthy state. In the acute and chronic hepatitis of India it is considered almost a specific; but here its use must be generally preceded by bleeding, and carried to the extent of exciting *ptyalism*. In chronic inflammation of the mucous and serous membranes, the alterative effects of mercury are sometimes attended with much benefit. In many of these cases effusion has

taken place; and under these circumstances the mercury often proves useful, by promoting the absorption of the effused fluid, as well as by removing the chronic inflammation on which the effusion depends. Hence it is that the remedy is often given with advantage in chronic forms of meningitis, bronchitis, pleuritis, pneumonia, dysentery, rheumatism, &c., and in hydrocephalus, hydrothorax, ascites, and general dropsy.

Mercury may also be advantageously resorted to in certain states of febrile disease. In some forms of the remittent fever of our own country, a particular stage of its course is marked by a dry tongue, torpor of the bowels, scanty urine, and an arid state of the surface. Here depletion by the lancet or leeches is often inadmissible, and the remedial measure most to be relied on is the judicious employment of mercury. It acts in such cases by increasing the secretions, and promoting the action of the exhalent capillaries, and, perhaps, by producing a new impression, incompatible with the action of the disease.

In syphilitic affections, mercury has been held to be, until of late years, an indispensable specific. Of its mode of action in these affections we know nothing, except that it operates by substituting its own peculiar action for that of the disease. Without entering upon the question of the necessity or non-necessity of mercury in venereal complaints, as out of place in this work, we are free to admit that the discussion which has grown out of it has shown that this remedy has sometimes been unnecessarily resorted to in affections resembling syphilis, though of a different character; and that the disease in question ought to be treated less empirically, and more on the general principles of combating morbid action occurring in other parts. Mercury also appears to exert a peculiar control over the morbid effects of lead; and hence in colica pictonum, it is accounted by some writers to act almost as a specific.

For inducing the specific effects of mercury on the constitution, blue pill or calomel is generally resorted to. In order to produce what we have called the insensible alterative effects of the metal, a grain or two of blue pill may be given in the twenty-four hours, or from a sixth to a fourth of a grain of calomel; or if a gentle ptyalism be our object, from three to five grains of the former, or a grain of the latter, two or three times a day. Where the bowels are peculiarly irritable, it is often necessary to introduce the metal by means of frictions with mercurial ointment; and, where a speedy effect is desired, the internal and external use of the remedy may be simultaneously resorted to.

The first observable effects of mercury in inducing ptyalism are a coppery taste in the mouth, a slight soreness of the gums, and an unpleasant sensation in the sockets of the teeth when the jaws are firmly closed. Shortly afterwards the gums begin to swell, a line of whitish matter is seen along their edges, and the breath is infected with a peculiar and very disagreeable smell, called the mercurial fetor. The saliva at the same time begins to flow; and, if the affection proceeds, the gums, tongue, throat, and face are much swollen; ulcerations attack the lining membrane of the mouth and fauces; the jaws become excessively painful; the tongue is coated with a thick whitish fur; and the saliva flows in streams from the mouth. It occasionally happens, that the affection thus induced in the mouth proceeds to a dangerous extent, inducing extensive ulceration, gangrene, and even hemorrhage. The best remedies are the various astringent and detergent gargles, used sufficiently weak, as the parts are extremely tender. In cases attended with swelling and protrusion of the tongue, the wash is best applied by injection, by means of a large syringe. We have found lead-water among the

best local applications in these cases; and dilute solutions of chlorinated soda or of chlorinated lime, while they correct the fetor and add to the comfort of the patient, will be found to exert a curative influence on the ulcerated surfaces.

While the system is under the specific action of mercury, the blood is more watery, less charged with albumen, fibrin, and red globules, and loaded with a very fetid fatty matter. (*Dr. S. Wright*, as quoted by *Christison*.) When drawn from a vein, it exhibits the same appearance as in inflammatory diseases.

In the foregoing observations we have described the ordinary effects of mercury; but occasionally, in peculiar constitutions, its operation is quite different, being productive of a dangerous disturbance of the vital functions. Mr. Pearson of London has given a detailed account of this occasional peculiarity in the operation of mercury in his work on the venereal disease. The symptoms which characterize it are a small frequent pulse, anxiety about the præcordia, pale and contracted countenance, great nervous agitation, and alarming general debility. Their appearance is the signal for discontinuing the mercury; as a further perseverance with it might be attended with fatal consequences. Mercury is also productive of a peculiar eruption on the skin, which will be found described by the systematic writers under the various names of *hydrargyria*, *eczema mercuriale*, and *lepra mercurialis*.

Those who work in mercury and are, therefore, exposed to its vapours, such as water-gilders, looking-glass silverers, and quicksilver miners, are injured seriously in their health, and not unfrequently affected with shaking palsy, attended with vertigo and other cerebral disorders.

Mercury is sometimes given in the metallic state, in the quantity of a pound or two in obstructions of the bowels, to act by its weight; but the practice is of doubtful advantage.

Pharmaceutical Preparations. We shall close our account of mercury by presenting a tabular view of all the officinal preparations of this metal, to be found in the United States and British Pharmacopœias. Mercury is officinal,—

HYOSCYAMUS. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solanaceæ.

Gen. Ch. Corolla funnel-form, obtuse. *Stamens* inclined. *Capsules* covered with a lid, two-celled. *Willd.*

Hyoscyamus niger. Willd. *Sp. Plant.* i. 1010; Woodv. *Med. Bot.* p. 204. t. 76; Bigelow, *Am. Med. Bot.* i. 161. Henbane is usually a biennial plant, with a long, tapering, whitish, fleshy, somewhat branching root, bearing considerable resemblance to that of parsley, for which it has been eaten by mistake. The stem is erect, round, branching, from one to three feet in height, and thickly furnished with leaves. These are large, oblong ovate, deeply sinuated, with pointed segments, undulated, soft to the touch, and at their base embrace the stem. The upper leaves are generally entire. Both the stem and leaves are hairy, viscid, and of a sea-green colour. The flowers form long, one-sided, leafy spikes, which terminate the branches, and hang downwards. They are composed of a calyx with five pointed divisions, a funnel-shaped corolla, with five unequal, obtuse segments at the border, five stamens inserted into the tube of the corolla, and a pistil with a blunt, round stigma. Their colour is an obscure yellow, beautifully variegated with purple veins. The fruit is a globular two-celled capsule, covered with a lid, invested with the persistent calyx, and containing numerous small seeds, which are discharged by the horizontal separation of the lid. The whole plant has a rank offensive smell.

The *H. niger* seems to be susceptible of considerable diversity of character, giving rise to varieties which have by some been considered as

distinct species. Thus the plant is sometimes annual, the stem simple, the leaves more deeply incised and less hairy than in the common variety, and the flowers yellow without the purple streaks. It has not been determined whether any difference of medical properties is connected with these diversities of character. The plant is found in the northern and eastern sections of the United States, occupying waste grounds in the vicinity of the older settlements, particularly graveyards, old gardens, and the foundations of ruined houses. We have seen a specimen brought from the ruins of Ticonderoga. It is rare, however, in this country, of which it is not a native, having been introduced from Europe. In Great Britain, France, Germany, and other parts of Europe, it grows abundantly along the roads, around villages, amidst rubbish, and in uncultivated places. It flowers in June and July.

The *H. albus*, so named from the whiteness of its flowers, is used in France indiscriminately with the former species, which it resembles exactly in medicinal properties.

All parts of the *Hyoscyamus niger* are possessed of activity. The leaves are the part usually employed, but both these and the seeds are recognised in the U. S. and London Pharmacopœias. Much of the efficacy of henbane depends upon the time at which it is gathered. The leaves should be collected soon after the plant has flowered. In the biennial plant, those of the second year are asserted by Dr. Houlton to be greatly preferable to those of the first. The latter, he informs us, are less clammy and fetid, yield less extractive matter, and are medicinally much less efficient. As the plant is sometimes destroyed by the severe winters in England, no leaves of the second year's growth are obtainable, and the market is on these occasions supplied with the medicine of inferior quality. This is, perhaps, one of the causes of its great inequality of strength, and uncertainty of operation. The root also is said to be much more poisonous in the second year than the first.

Properties. The recent leaves have, when bruised, a strong, disagreeable, narcotic odour, somewhat like that of tobacco. Their taste is mucilaginous, and very slightly acrid. When dried, they have little smell or taste. Thrown upon the fire, they burn with a crackling noise, as if they contained a nitrate, and at the same time emit a strong odour. Their virtues are completely extracted by diluted alcohol. The watery infusion is of a pale yellow colour, insipid, with the narcotic odour of the plant. The leaves have been analyzed by Lindbergsen, who obtained from them a narcotic principle. The seeds are very small, roundish, compressed, somewhat kidney-shaped, a little wrinkled, of a gray or yellowish-gray colour, of the odour of the plant, and an oleaginous bitterish taste. Analyzed by Brandes, they yielded 24.2 per cent. of fixed oil, 1.4 of a solid fatty substance, traces of sugar, 1.2 of gum, 2.4 of bassorin, 1.5 of starch, 3.4 of a substance soluble in water, insoluble in alcohol, and precipitated by infusion of galls (phyteumacolla, Brandes), 4.5 of albumen soluble or coagulated, 26.0 of vegetable fibre, 24.1 of water, and 9.7 of saline matters, including an alkaline principle called *hyoscyamin* or *hyoscyamia*, combined with malic acid. But the process employed by Brandes for separating this principle, has not succeeded in other hands; and it was doubtful whether the substance obtained by that experimentalist was really what he supposed it to be. Geiger and Hesse were the first to demonstrate the existence of an organic alkali in *hyoscyamus*. Its extraction from the plant is somewhat difficult, in consequence of its strong tendency to undergo a change by the contact of alkaline solutions, which render it very soluble in water. The following is the

process of the last mentioned chemists. The seeds of the plant are macerated in alcohol; the tincture thus obtained is evaporated by a very gentle heat, decolorized by repeated additions of lime and sulphuric acid, with filtration after each addition, and then still further concentrated by evaporation; an excess of powdered carbonate of soda is added, and the precipitate produced is separated, as speedily as possible, from the alkaline carbonate by expressing and treating it with absolute alcohol, while the mother waters are at the same time treated with ether; the alcoholic and ethereal liquors are united, again treated with lime, filtered, decolorized with animal charcoal, and evaporated by a very gentle heat. If the hyoscyamia now deposited should still be coloured, it will be necessary to combine it anew with an acid, and to treat as before, in order to obtain it quite pure. The product is very small.

Hyoscyamia crystallizes in colourless, transparent, silky needles, which are without odour, of an acrid disagreeable taste, slightly soluble in water, very soluble in alcohol and ether, and volatilizable with little change if carefully distilled. It is quickly altered by contact with water and an alkali, and when heated with potassa or soda is completely decomposed, with the disengagement of ammonia. It neutralizes the acids, forming with them crystallizable salts. The infusion of galls precipitates it from its aqueous solution. Both the alkali and its salts are very poisonous; and the smallest quantity, introduced into the eye, produces a dilatation of the pupil, which continues for a long time.

Henbane leaves yield, by destructive distillation, a very poisonous empyreumatic oil.

Medical Properties and Uses. Hyoscyamus ranks among the narcotics. In moderate quantities it gently accelerates the circulation, increases the general warmth, occasions a sense of heat in the throat, and after a short period induces sleep. This action is sometimes attended with vertigo, pain in the head, and dilated pupils; and the medicine occasionally acts as a diaphoretic or diuretic, and even produces a pustular eruption. It does not constipate like opium, but, on the contrary, often proves laxative. In over doses it powerfully irritates the brain and alimentary canal, causing dilatation of the pupil, disordered vision, loss of speech, delirium or stupor, convulsions, paralysis, pain in the bowels, diarrhœa, great arterial prostration, petechiæ, and other alarming symptoms, which sometimes end in death. Dissection exhibits marks of inflammation of the stomach and bowels. The poisonous effects are to be counteracted in the same manner as those of opium. Acid drinks, such as lemon-juice and vinegar, are recommended after the evacuation of the stomach. Numerous instances might be adduced from authors to prove the deleterious influence of all parts of the *H. niger*, when taken in large quantities. Upon inferior animals its effects are not always the same. While it proves fatal to birds and dogs, the leaves are eaten with entire impunity by horses, cows, sheep, goats, and swine. It is not impossible that injury has in some cases resulted from the use of milk derived from cows or goats which had been feeding on henbane.

The remedial operation of hyoscyamus is anodyne and soporific. The medicine was known to the ancients, and was employed by some of the earlier modern practitioners; but had fallen into disuse, and was almost forgotten, when Baron Störck again introduced it into notice. By this celebrated physician and some of his successors it was prescribed in numerous diseases, and, if we may credit their testimony, with the happiest effects; but subsequent experience of its operation has been such as very much to narrow the extent of its application. It is at present used almost exclusively

to relieve pain, procure sleep, or quiet irregular nervous action; and is not supposed to exercise any specific curative influence over particular diseases. Even for the purposes which it is calculated to answer, it is infinitely inferior to opium or its preparations; and is generally resorted to only in cases in which the latter remedy is from peculiar circumstances deemed inadmissible. Hyoscyamus has one great advantage over opium in certain cases, that it has no tendency to produce constipation. The diseases to which it is applicable it would be useless to enumerate, as there are few complaints in which circumstances might not be such as to call for its employment. Neuralgic and spasmodic affections, rheumatism, gout, hysteria, and various pectoral diseases, as catarrh, pertussis, asthma, phthisis, &c. are among those in which it is most frequently prescribed. In Europe, where the fresh leaves are readily obtained, it is often applied externally in the shape of lotion, cataplasm, or fomentation, to allay pain and irritation, in scrofulous or cancerous ulcers, scirrhus, hemorrhoidal, or other painful tumours, gouty and rheumatic swellings, and nervous headache. The smoke of the leaves or seeds has also been used in toothache; but the practice is deemed hazardous. The effect of henbane in dilating the pupil, when applied to the conjunctiva, has already been noticed. For this purpose it is used by European oculists, previously to the operation for cataract. An infusion of the leaves, or a solution of the extract, is dropped into the eye. The effect is usually greatest at the end of four hours from the time of application, and in twelve hours ceases entirely. Vision is not impaired during its continuance. Reisinger recommends a solution of hyoscyamia in the proportion of one grain to twenty-four of water, of which one drop is to be applied to the eye.

Henbane may be given in substance, extract, or tincture. The dose of the powdered leaves is from five to ten grains; that of the seeds somewhat smaller. The common extract, or inspissated juice of the fresh leaves (*Extractum Hyoscyami, U. S.*), is exceedingly variable and precarious in its operation, being sometimes active, sometimes almost inert. The usual dose is two or three grains, repeated and gradually increased till the desired effect is obtained. Cullen rarely procured the anodyne operation of the medicine till he had carried the dose to eight, ten, or even fifteen or twenty grains. Collin pushed it to thirty-six grains; and Professor Fouquier, who experimented largely with hyoscyamus in the Hôpital de la Charité, gave two hundred and fifty grains of the extract during twenty-four hours, without any specific or curative impression. (Richard, *Elem. Hist. Nat. Med.*) The alcoholic extract prepared from the recently dried leaves (*Extractum Hyoscyami Alcoholicum, U. S.*) is said to be more certain and effectual. The dose of this to begin with is one or two grains, which may be increased gradually to twenty or even thirty grains. The dose of the tincture is one or two fluidrachms. A good plan in administering any of the preparations of hyoscyamus is to repeat the dose every hour or two till its influence is felt.

ICHTHYOCOLLA. U.S.

Isinglass.

"The swimming bladder of *Acipenser Huso*, and other species of *Acipenser*." U. S.

Fish-glue; *Ichthyocolle*, colle de poisson, *Fr.*; Hausenblase, Fischleim, *Germ.*; Colla di pesce, *Ital.*; Cola de pescado, *Span.*

Isinglass is a gelatinous substance, prepared chiefly from the sounds or swimming bladders of fishes, especially those of different species of sturgeon. Though no longer retained by any of the British Colleges in their officinal catalogues, it still has a place in the Pharmacopœia of the United States, and being universally kept in the shops, requires at least a brief notice in the present work.

In most fishes there is a membranous bag, placed in the anterior part of the abdomen, communicating frequently, though not always, by means of a duct, with the œsophagus or stomach, and containing usually a mixture of oxygen and nitrogen gases in various proportions. From the supposition that it was intended by its expansion or contraction to enable the fish to rise or sink in the water, it has been denominated *swimming bladder*. It is of different shape in different fishes, and consists of three coats, of which the two interior are thin and delicate, the outer tough and of a silvery whiteness.

The *Acipenser Huso*, or *beluga* of the Russians, is particularly designated by the Pharmacopœia as the species of sturgeon from which isinglass is procured; but three others, the *A. Ruthenus*, or sterlet, *A. Sturio*, or common sturgeon, and *A. stellatus*, or starred sturgeon, also furnish large quantities to commerce. All these fish inhabit the interior waters of Russia, especially the Wolga, and other streams which empty into the Caspian Sea. Immense quantities are annually taken and consumed as food by the Russians. The air-bags are removed from the fish, and, having been slit open and washed in water in order to separate the blood, fat, and adhering extraneous membranes, are spread out, and when sufficiently stiffened are formed into cylindrical rolls, the ends of which are brought together and secured by pegs. The shape given to the roll is that of a staple, or more accurately that of a lyre, which it firmly retains when dried. Thus prepared it is known in commerce by the name of *staple isinglass*, and is distinguished into the *long* and *short staple*. Sometimes the membranes are dried in a flat state, or simply folded, and then receive the name of *leaf* or *book isinglass*. The scraps or fragments of these varieties, with various other parts of the fish, are boiled in water, which dissolves the gelatin, and upon evaporation leaves it in a solid state. This is called *cake isinglass*, from the shape which it is made to assume. It is sometimes, however, in globular masses. Of these varieties the *long staple* is said to be the best; but the finest *book isinglass* is not surpassed by any brought to this country. It is remarkable for its beautiful iridescence by transmitted light. One hundred grains of this isinglass dissolve in ten ounces of water, forming a tremulous jelly when cold, and yield but two grains of membranous insoluble residuum. The price of it is from three dollars and a half to four dollars a pound. That in *cakes* is brownish, of an unpleasant odour, and employed only in the arts. Inferior kinds, with the same commercial titles, are said to be prepared from the peritoneum and intestines of the fish.

Isinglass little inferior to the Russian is made in Iceland from the sounds of the cod and ling.

Considerable quantities of isinglass are manufactured in New England from the intestines of the cod—*Morrhua Americana* (Storer, *Report on Fishes of Mass.* 1839)—and of some of its allied fishes. This sort is in the form of thin ribbons several feet in length, and from an inch and a half to two inches in width. It sells at from seventy-five to ninety cents a pound. One hundred grains dissolve almost entirely in water, leaving but two grains of insoluble membrane, and form a tremulous jelly when cold with eight ounces of water. It is, therefore, as pure and nearly as strong a gelatin as the Russian isinglass, but retains a fishy taste and odour, which render it unfit for culinary or medicinal purposes.

We receive from Brazil the air-bladders of a large fish, prepared by drying them in their distended state. They are oblong, tapering and pointed at one end, bifid with the remains of their pneumatic duct at the other, and of a firm consistence.

Isinglass of a good quality is also made, in New York, from the sounds of the weak fish—*Otolithus regalis* of Cuvier (Storer, *Rep. on Fishes of Mass.* p. 33)—and perhaps of other fishes caught in the neighbourhood. The sounds are dried whole, or merely split open, and vary much in size and texture, weighing from a drachm up to an ounce.

An article called "*refined or transparent isinglass*," is made by dissolving the New England isinglass in hot water, and spreading the solution to dry on oiled muslin. It is in very thin transparent plates, and is an excellent glue, but retains a strong fishy odour. It sells at about two thirds the price of the Russia isinglass.

An article called *Cooper's gelatin*, has been introduced as a substitute for isinglass in the making of jellies. It appears to be the dried froth of a solution of pure bone glue.*

Isinglass is sometimes kept in the shops cut into fine shreds, and is thus more easily acted on by boiling water.

In its purest form it is whitish, semi-transparent, of a shining, pearly appearance, and destitute of smell and taste. The inferior kinds are yellowish and more opaque. In cold water it softens, swells up, and becomes opalescent. Boiling water entirely dissolves it, with the exception of a minute proportion of impurities, amounting, according to Mr. Hatchet, to less than two parts in the hundred. The solution on cooling assumes the form of a jelly, which consists of pure gelatin and water. Isinglass is in fact the purest form of *gelatin* with which we are acquainted, and may be used whenever this principle is required as a test. It is insoluble in alcohol, but is dissolved readily by most of the diluted acids, and by solutions of the alkalies. It has a strong affinity for tannin, with which it forms an insoluble compound. Boiled with concentrated sulphuric acid, it is converted into a peculiar saccharine matter. Its aqueous solution speedily putrefies.

Medical Properties and Uses. Isinglass has no peculiar medical properties. It may be given internally, in the form of jelly, as a highly nutritious article of diet; but it has no advantages over the jelly prepared from calves-feet. Three drachms impart sufficient consistency to a pint of water. It is employed in the arts for clarifying liquors, and imparting lustre to various woven fabrics. Added in small quantities to vegetable jellies, it gives them a tremulous appearance, which they want when unmixed. As a test of tannin it is used in solution, in the proportion of a drachm to ten fluidounces of distilled water. It forms the basis of the English court-plaster. W.

* We have derived the above facts in relation to American isinglass from Mr. D. B. Smith. (See also a paper by this author in the *Journ. of the Phil. Col. of Pharm.* iii. 17 and 92.)

Gen. Ch. Receptacle naked. Seed-down simple. *Anthers* ending in two bristles at the base. *Willd.*

Inula Helenium. Willd. *Sp. Plant.* iii. 2089; Woodv. *Med. Bot.* p. 64. t. 26. Elecampane has a perennial root, and an annual stem, which is round, furrowed, villous, leafy, from three to six feet high, and branched near the top. The leaves are large, ovate, serrate, crowded with reticular veins, smooth and deep green upon the upper surface, downy on the under, and furnished with a fleshy midrib. Those which spring directly from the root are petiolate, those of the stem sessile and embracing. The flowers are large, of a golden-yellow colour, and stand singly at the ends of the stem and branches. The calyx exhibits several rows of imbricated ovate scales. The florets of the ray are numerous, spreading, linear, and tridentate at the apex. The seeds are striated, quadrangular, and furnished with a simple somewhat chaffy pappus.

This large and handsome plant is a native of Europe, where it is also cultivated for medical use. It has been introduced into our gardens, and has become naturalized in some parts of the country, growing in low meadows, and on the roadsides, from New England to Pennsylvania. It flowers in July and August. The roots, which are the officinal part, should be dug up in autumn, and in the second year of their growth. When older they are apt to be stringy and woody.

The fresh root of elecampane is very thick and branched, having whitish cylindrical ramifications which are furnished with thread-like fibres. It is externally brown, internally whitish and fleshy; and the transverse sections present radiating lines. The dried root, as found in the shops, is usually in longitudinal or transverse slices, and of a grayish colour internally. The smell is slightly camphorous, and, especially in the dried root, agreeably aromatic. The taste, at first glutinous and said to resemble that of rancid soap, becomes, upon chewing, warm, aromatic, and bitter. Its medical virtues are extracted by alcohol and water, the former becoming most strongly impregnated with its bitterness and pungency. A peculiar principle resembling starch was discovered in elecampane by Rose, a chemist of Berlin, who named it *alantin*; but the title *inulin*, proposed by Dr. Thomson, has been generally adopted. It differs from starch in being deposited unchanged from its solution in boiling water when the liquor cools, and in giving a yellowish instead of a blue colour with iodine. It has been found in the roots of several other plants. Besides this principle, elecampane contains, according to John, a white, concrete substance, called *helenin*, intermediate in its properties between the essential oils and camphor, and separable by distillation with water; a bitter extractive, soluble in water and alcohol; a soft, acrid, bitter resin, having an aromatic odour when heated; gum; albumen; lignin; traces of volatile oil; a little wax; and various saline substances.

Medical Properties and Uses. Elecampane is tonic and gently stimulant, and has been supposed to possess diaphoretic, diuretic, expectorant, and emmenagogue properties. By the ancients it was much employed, especially in the complaints peculiar to females; and it is still occasionally resorted to in cases of retained or suppressed menstruation. In this country it is chiefly used in chronic diseases of the lungs, and is sometimes beneficial when the affection of the chest is attended with weakness of the digestive organs, or with general debility. From a belief in its deobstruent and diuretic virtues, it was formerly prescribed in chronic engorgements of the abdominal viscera, and the dropsy to which they so often give rise. It has also been highly recommended both as an internal and external remedy in tetter, psora, and other diseases of the skin. The usual modes of administration are in powder and decoction. The dose of the former is from a scruple to a drachm. The decoction may be prepared by boiling half an ounce of the root in a pint of water, and given in the dose of one or two fluidounces.

IODINUM. U.S.

 *Iodine.*

Off. Syn. IODINIUM. *Lond., Dub.;* IODINEUM. *Ed.*

Iode, Fr.; Iod, Germ.; Iodina, Ital., Span.

Iodine is an elementary non-metallic body, having many analogies to chlorine. It was discovered in 1812 by Courtois, a soda manufacturer of Paris. Some years after its discovery, its therapeutic powers were tried; and these having been found valuable, it has gradually come into general use, so that at the present day it is universally recognised as a standard remedy.

Natural State and Preparation. Iodine exists in certain marine vegetables, particularly the fuci or common sea-weeds; in the animal kingdom, in sponge, the oyster, various polypi, and cod's liver oil; and in the mineral kingdom, in sea water in minute quantity, in certain salt springs, united with silver in a rare Mexican mineral, and in a zinc ore from Silesia. It was first discovered in the United States in the water of the Congress Spring, at Saratoga, by Dr. William Usher; and afterwards in the same water by Dr. J. H. Steel, who ascertained it to be in the state of iodide of sodium. (See p. 114.) It was also detected in small quantity in the Kenhawa saline waters, by the late Professor Emmet of the University of Virginia. In sea-weeds, the iodine probably exists in the shape of iodide of sodium. In both England and France, sea-weeds are burnt for the sake of their ashes; the product being a dark-coloured fused mass, called *kelp*. This substance contains, besides carbonate of soda and iodide of sodium, more or less common salt, chloride of potassium, sulphate of soda, &c.

Preparation. It is from kelp that iodine is obtained, and that procured in Great Britain is exclusively manufactured in Glasgow. The kelp which, on an average, contains a 224th part of iodine, is lixiviated in water, in which about half dissolves. The solution is concentrated to a pellicle, whereby all the salts, except the iodide of sodium, are almost completely separated, either during the concentration, or the subsequent cooling, being less soluble than the iodide. The remaining liquor, which is dense and dark-coloured, is rendered sour by sulphuric acid, whereby carbonic acid, sulphuretted hydrogen and sulphurous acid are evolved, and sulphur is deposited. The liquor is now introduced into a leaden still, and distilled with

a portion of deutoxide of manganese into a series of glass receivers, inserted into one another, in which the iodine is condensed. In this process the iodide of sodium is decomposed, and the iodine evolved; and the sulphuric acid, deutoxide of manganese, and sodium unite, so as to form the sulphate of protoxide of manganese and sulphate of soda.

Properties. Iodine is a soft, friable, opaque substance, in the form of crystalline scales of a bluish-black colour and metallic lustre. It possesses a strong and peculiar odour, somewhat resembling that of chlorine, and a hot acid taste. Applied to the skin, it produces an evanescent yellow stain. Its sp. gr. is a little less than 5. It is a volatile substance, and evaporates even at common temperatures, provided it be in a moist state. When heated it evaporates more rapidly, and when the temperature reaches 225° , it fuses, and sublimes in a rich purple vapour, a property which suggested its name. Its vapour has the sp. gr. of 8.7, and is the heaviest æriform substance known. If inhaled mixed with air, it excites cough and irritates the nostrils. When it comes in contact with cool surfaces, it condenses in brilliant steel-gray crystals. Iodine is soluble in 7000 times its weight of water, and in a much smaller quantity of alcohol or ether. Its solution in water has no taste, a feeble odour, and a light brown colour; in alcohol or ether, a deep brown hue. Its solubility in water is very much increased by the addition of certain salts, as the chloride of sodium, nitrate of ammonia, or iodide of potassium. In chemical habitudes, it resembles chlorine; but its affinities are weaker. Its equivalent number is 126.3. It combines with most of the non-metallic, and nearly all the metallic bodies, forming, when the combination is not acid, the class of compounds called *iodides*. Some of these, as the iodides of iron, mercury, lead, potassium, and sulphur, are officinal. It forms with oxygen one oxide, and three acids, the *iodous*, *iodic*, and *periodic acids*, and with hydrogen, a gaseous acid, analogous in properties and constitution to the muriatic, called *hydropodic acid*.

Iodine may, in most cases, be recognised by its characteristic purple vapour; but where this cannot be made evident, it is detected unerringly by starch, which produces with it an insoluble combination of a deep blue colour. This test was discovered by Colin and Gaultier de Claubry, and, according to Stromeyer, is so delicate, that it will indicate the presence of iodine in 450,000 times its weight of water. In order that the test may succeed, the iodine must be in a free state, and the solutions cold. To render it free where it happens to be in combination, a little nitric acid must be added to the solution suspected to contain it.

Adulterations. Iodine is said to be occasionally adulterated with mineral coal, charcoal, plumbago, and black oxide of manganese; but neither Dr. Pereira nor Dr. Christison has found any of these substances in samples of iodine which they have examined. They are easily detected by their fixed nature, while pure iodine is wholly vaporizable, or by their insolubility in alcohol. An impurity which is almost always present in commercial iodine is water. Several years ago Dr. Christison called attention to this fact, and until within a recent period he had not met with any British iodine which did not contain from fifteen to twenty per cent. of moisture. This impurity is of consequence, as it interferes with uniformity in the iodine preparations. If considerable, it is easily detected by the iodine adhering to the inside of the bottle. The Edinburgh Pharmacopœia has given a test which detects all impurity beyond two per cent. It is founded upon the fact that pure iodine, diffused in water, forms a clear solution with a certain proportion of quicklime. Accordingly, an amount

of quicklime is directed which is not quite sufficient to form a *colourless* solution with iodine containing two per cent. of impurity; and, hence, if the sample contain more impurity, the lime is competent to produce this effect. With this explanation, the Edinburgh directions for applying the test will be understood. "Thirty-nine grains [of iodine] with nine grains of quicklime and three ounces of water, when heated short of ebullition, slowly form a perfect solution, which is yellowish or brownish if the iodine be pure, but colourless if there be above two per cent. of water or other impurity."

The Edinburgh College, in view of the almost uniform presence of water in commercial iodine, and of its consequent unfitness "for making pharmaceutical preparations of uniform strength," directs it to "be dried by being placed, in a shallow basin of earthenware, in a small confined space of air, with ten or twelve times its weight of fresh-burnt lime, till it scarcely adheres to the inside of a dry bottle."

Medical Properties and Uses. Iodine was first employed as a medicine in 1820, for the cure of goitre, by Dr. Coindet, Senior, of Geneva. It operates as a general excitant of the living actions, but particularly of the absorbent and glandular systems. Its special actions are varied by its degree of concentration, state of combination, dose, &c.; and hence, under different circumstances of the remedy and of the system, it is deemed capable of acting as a corrosive, irritant, desiccant, tonic, diuretic, diaphoretic, and emmenagogue. It probably acts by entering into the circulation; at least it has been proved by Dr. A. Buchanan of Glasgow, that it enters a number of the secretions, particularly the urine and saliva, not, as he believes, in an uncombined state, but in that of hydriodic acid. Cantu detected it not only in the urine and saliva, but also in the sweat, milk, and blood, and always as hydriodic acid or an iodide. Its tonic operation is evinced by its strengthening the digestive organs, and increasing the appetite, which are the most constant effects of its use. Salivation is occasionally produced by it, and sometimes soreness of mouth only. In some cases, pustular eruptions and coryza have been produced; effects most apt to occur when the remedy is given in the form of iodide of potassium. When taken in an overdose it acts as an irritant poison. In doses of two drachms, administered to dogs, it produced irritation of the stomach, and death in seven days; and the stomach on dissection was found studded with numerous little ulcers of a yellow colour. In a dose of from four to six grains in man, it produces a sense of constriction in the throat, sickness and pain at the stomach, and at length vomiting and colic. These facts demonstrate the activity of iodine, and show the necessity of caution in its exhibition. Even when given in medicinal doses, especially if these be rather large, it sometimes produces dangerous symptoms; such as restlessness, palpitation, a sense of burning along the gullet, excessive thirst, acute pain in the stomach, vomiting and purging, violent cramps, rapid and extreme emaciation, and frequent pulse. This condition of the system, in which the poisonous effects of iodine are developed, is called *iodism*. Though it may be produced by incautious doses of the medicine, too long continued, still it must be admitted that it sometimes arises, under other circumstances, from causes not well explained. On the other hand, large doses have been given for a long time, with perfect impunity. This variable operation of iodine may in some measure be accounted for by the variable condition of the stomach, and the more or less amylaceous character of the food; starch having the power of uniting with iodine and rendering it mild. Upon the appearance of the first symptoms of fever or general nervous disturbance, indicating the approach of

iodism, the remedy should be instantly laid aside. Dr. Lugol, of Paris, who has used iodine more methodically than any other practitioner, has never observed these alarming effects to arise from the remedy, given in the small doses and in the state of dilution in which he is in the habit of prescribing it. He has not found it to cause emaciation, hæmoptysis, pulmonary tubercles, or other bad effects. On the contrary, in the hospital of St. Louis, the theatre of his extensive trials of the remedy in scrofulous diseases, many of the patients gained flesh and improved in general health.

Notwithstanding this testimony, we have indubitable evidence that rapid emaciation is occasionally produced by iodine; and a long course of the remedy, as when administered for the cure of bronchocele, has in some instances produced absorption of the mammæ. The wasting of the testicles, under similar circumstances, is comparatively rare. Dr. R. Coates, of this city, reports a case in the Medical Examiner, of the complete absorption of the female breast from iodine; but the mammæ recovered their original development after the lapse of a year.

Iodine has been principally employed in diseases of the absorbent and glandular systems. In ascites it has been used with success by Dr. Baron. It is said not to act efficaciously while the abdomen is tense, and the absorbents consequently compressed, but operates after this condition is removed by tapping. Dr. Bardsley recommends it in that form of ascites which is connected with diseased liver. It has been used successfully by some British practitioners in ovarian tumours, but failed in the hands of others. In glandular enlargements and morbid growths, its use has proved more efficacious than, perhaps, in any other class of diseases. Dr. Coindet discovered its extraordinary power in promoting the absorption of the thyroid gland in bronchocele; and it has been used with more or less success in enlargements of the liver, spleen, mammæ, testes, and uterus. When used in bronchocele, its good effects are commonly shown in three weeks, but often, not until the treatment has been continued for a longer time. In induration and enlargement of the liver, where mercury has failed or is inadmissible, iodine forms our best resource. In chronic diseases of the uterus, attended with induration and enlargement, and in hard tumours of the cervix, and indurated puckerings of the edges of the os tincæ, iodine has occasionally effected a cure, administered internally, and rubbed into the cervix in the form of ointment for ten or twelve minutes every night. The emmenagogue power of iodine has been noticed by several practitioners; and Dr. Lugol mentions instances, among his scrofulous patients, in which it cured obstructed and painful menstruation. It has been recommended in gleet, and also in gonorrhœa and leucorrhœa, after the inflammatory symptoms have subsided. In pseudo-syphilis and the cachexy arising from the abuse of mercury, it is one of our best remedies; but to the treatment of these cases iodide of potassium is considered to be best suited. (See *Potassii Iodidum*.) In chronic rheumatism it is a favourite remedy with some, particularly in the form of iodide of potassium; and by Gendrin it has been employed in the acute forms of gout, with the effect, as he supposed, of cutting short the fits. Dr. Manson, of Nottingham, England, in his work published in 1825, on the medical effects of iodine, has recorded cases of its efficacy in several nervous diseases, such as chorea and paralysis. In various scaly cutaneous diseases, the internal and external use of the preparations of iodine is very much relied on.

It is in scrofulous diseases that the most interesting results have been obtained by the use of iodine. Dr. Coindet first directed public attention to its effects in scrofula, and Dr. Manson reported a number of cases of this

disease in the form of enlarged glands, ulcers, and ophthalmia, occurring in his practice between 1821 and 1824, in a large proportion of which the disease was either cured or meliorated, and the general health much improved. But we are indebted to Dr. Lugol for the most extended and valuable researches in relation to the use of iodine in the different forms of scrofula. This physician began his trials with the remedy in the hospital Saint Louis in 1827, and made known his results in three Memoirs published in 1829–30 and 31. These memoirs give the detail of a success which would stagger belief, were not the results substantiated by committees of distinguished physicians of the French Royal Academy of Sciences. The scrofulous affections in which Dr. Lugol succeeded by the administration of iodine were glandular tubercles, especially of the neck, ophthalmia, ozæna, noli me tangere (dartre rongeante scrophuleuse), and fistulous and carious ulcers. He also obtained favourable results in some cases of scrofulous syphilis by the use of the iodide of mercury. In connexion with Dr. Lugol's results in scrofulous affections, it may be proper to mention that Dr. Manson derived benefit from the use of iodine in white swelling, hip-joint disease, and distortions of the spine, diseases generally admitted to be more or less dependent on the scrofulous taint.

Iodine is employed both internally and externally. Internally it is sometimes used in the form of tincture; but Dr. Lugol objects to this preparation as of unequal strength, and as being liable to have the iodine precipitated by water on the surface of the stomach, where it is apt to produce too irritating an action. (See *Tinctura Iodini Composita*.) This physician prefers a mixed solution of iodine and iodide of potassium in distilled water. He employs three strengths, namely, three-fourths of a grain, one grain, and a grain and a quarter of iodine to half a pint of distilled water; the quantity of iodide of potassium being in each solution double the quantity of the iodine.* These solutions are permanent, perfectly transparent, and of an orange colour. The London College has imitated this combination in a new official formula. (See *Liquor Potassii Iodidi Compositus*.) The mode of administration employed by Dr. Lugol for his solutions, is to give two-thirds of the weakest solution, or half a grain of iodine daily for the first fortnight; the weakest solution entire for the second and third fortnight; the medium solution during the fourth and fifth fortnight; and lastly, in some cases, the strongest solution for the remainder of the treatment. In the majority of cases, however, he had not occasion to resort to the strongest solution. He gives half the daily quantity in the morning fasting, and the other half, an hour before dinner; each portion being slightly sweetened at the moment of taking it. For the convenience of making the weak iodine solution, or of administering the remedy by drops, Dr. Lugol prepares a concentrated solution, consisting of a scruple of iodine, and two scruples of iodide of potassium dissolved in seven fluidrachms of water.† Of this solution the dose is six drops twice a day, (in the morning fasting, and an hour before dinner,) in a glass of sweetened water, gradually increased weekly by two drops at a time, until the dose reaches to thirty or thirty-six drops. For children under seven years, the dose is two drops twice a day, gradually increased to five. This solution has been made official in the last edition

* In the original Memoir of Dr. Lugol, the grains are French, and the quantity of water eight French ounces; but to facilitate prescription we have supposed them English grains, and have substituted half a pint for the eight French ounces of water; changes which will not make the solutions materially stronger.

† In the original it is seven ounces; but from the context of the author, this is evidently a misprint for seven drachms.

of the United States Pharmacopœia. (See *Liquor Iodini Compositus*.) It will be observed that these doses are considerably smaller than those usually employed by Dr. Coindet.

The external treatment by iodine may be divided into local and general. By its use in this way it does not create a mere topical effect on the skin; but by its absorption produces its peculiar constitutional impression. Dr. Lugol has given a number of formulæ for preparations for the local use of iodine, a short account of which will be here given. His *iodine ointment* varies in strength from six to twelve grains of iodine, mixed with from two to four scruples of iodide of potassium, to the ounce of lard. (See *Unguentum Iodini Compositum*.) It has a mahogany colour, and is employed in frictions to scrofulous tumours, and as a dressing to scrofulous ulcers. The *ointment of protiodide of mercury* which he recommends, consists of from one to two scruples of the mercurial iodide to the ounce of lard. (See *Unguentum Hydrargyri Iodidi*.) Its proper colour is canary yellow; but occasionally it has a decided greenish tint, derived from the presence of protoxide of mercury, or an orange colour, when it contains the biniodide. This ointment, which has the advantage of producing very little pain, is used by Dr. Lugol in *noli me tangere*, and in scrofulous ulcers which have a syphilitic aspect. The *ointment of biniodide of mercury*, which is much more powerful, has also been used with apparent advantage in similar cases. (See *Unguentum Hydrargyri Biniodidi*.) Dr. Lugol's *iodine lotion* consists of from two to four grains of iodine to a pint of distilled water, the solution being rendered complete by the addition of double the quantity of iodide of potassium. This is used by injection, principally in scrofulous ophthalmia, ozæna, and fistulous ulcers. His *rubefacient solution* is formed by dissolving half an ounce of iodine and an ounce of iodide of potassium in six fluidounces of distilled water. This is useful for exciting scrofulous ulcers, for touching the eye-lids, and as an application to recent scrofulous cicatrices, to render them smooth and less prominent. A certain quantity of the rubefacient solution added to warm water, makes a convenient local bath for the arms, legs, feet, or hands; and mixed with linseed meal, or some similar substance, it forms a cataplasm, useful in particular cases, especially where the object is to promote the falling off of scabs. The only remaining local application to be mentioned, is what Dr. Lugol calls *iodine caustic*. It consists of iodine and iodide of potassium, each an ounce, dissolved in two ounces of distilled water, and is used to stimulate or destroy soft and fungous granulations. Its employment in this way has been attended with particularly good effects in *noli me tangere*.

The external application of iodine, when general, consists in the use of iodine baths, a mode of applying the remedy which originated with Dr. Lugol. This mode is considered very valuable by this physician, on account of the great extent of the skin, which furnishes the means of introducing a considerable quantity of iodine into the circulation, without deranging the digestive functions, an object of great importance, where the medicine produces irritation of the stomach. The iodine bath for adults, according to the formula of Dr. Lugol, should contain from two to four drachms of iodine, with double that quantity of iodide of potassium, dissolved in water, in a *wooden* bath tub, the proportion of the water being about a gallon for every three grains of iodine employed. The quantity of ingredients for the baths of children is one-third as much as for adults, but dissolved in about the same proportional quantity of water. The quantity of iodine and iodide for a bath being determined on, it is best to dissolve them in a small quantity of water, (half a pint for example,) before they are added

to the water of the bath; as this mode of proceeding facilitates their thorough diffusion. In the composition of these baths, the iodide of potassium is used by Dr. Lugol merely to promote the solubility of the iodine, and not as a medicinal agent; as, upon trial, a bath containing the iodide alone proved nearly inert.

The iodine baths, which may be directed three or four times a week, usually produce a slight rubefacient effect; but, occasionally, a stronger impression, causing the epidermis to peel off, particularly of the arms and legs. The skin at the same time contracts a deep yellow tinge, which usually disappears in the interval between the baths.

Iodine has been used as a local application in erysipelas and chilblains. In these cases the tincture is recommended, brushed over and a little beyond the seat of inflammation, by means of a camel's hair pencil. The efficacy of the remedy in the former disease has been confirmed in two cases by Dr. Robert Burns, of Frankford, Pa. (*Med. Exam.* iv. 709.) We have tried it in one case with the effect of apparently cutting short the disease; but its application produced very severe pain, and we regretted that we had used the tincture undiluted. In cutaneous scrofula, the tincture has been found beneficial by Dr. Pereira, applied in the same way, having the effect of drying up the discharge and promoting cicatrization. The same topical application has been found useful in various scaly cutaneous diseases, such as lepra, psoriasis, &c.

Sir Charles Scudamore, Sir James Murray, and Dr. Corrigan have recommended the inhalation of iodine vapour in phthisis. The plan of Sir Charles is to inhale from a glass inhaler for ten minutes, two or three times a day, a small portion of a solution of ioduretted iodide of potassium, mixed with a saturated tincture of conium. The ioduretted solution is made by dissolving six grains, each, of iodine and iodide of potassium, in five ounces and three quarters of distilled water and a quarter of an ounce of alcohol. The dose for each inhalation is from half a drachm to a drachm of the iodine solution, gradually increased, with half a drachm of the tincture, added to a portion of water of the temperature of 120°, nearly sufficient to half fill the inhaler. We have no disposition to discourage the trial of new methods of treatment in phthisis by regular practitioners; but we cannot conceive of this inhaling treatment having any other than a palliative effect.

Since the publication of Dr. Lugol's memoirs, detailing his success with iodine in the treatment of scrofulous affections, his practice has been imitated and extended by several practitioners, and generally with encouraging results. Dr. Bermond, of Bordeaux, has succeeded with the iodine treatment in enlarged testicle from a venereal cause, scrofulous ophthalmia of six years' duration, and scrofulous ulcers and abscesses of the cervical and sub-maxillary glands. In numerous other cases of scrofula under his care, the iodine treatment proved beneficial; though, before its commencement, the cases underwent no improvement. The only peculiarity in Dr. Bermond's treatment, was that, in some cases, he associated opiate preparations with the iodine. In the case of ophthalmia which he treated, the collyrium employed consisted of tincture of iodine thirty drops, laudanum thirty-six drops, to four fluidounces of distilled water. When the local application of the iodine created much pain or rubefaction, he found advantage from combining extract of opium with it. A plaster which proved efficacious as an application to an enlarged parotid, in one of his cases, consisted of lead plaster (diachylon) and iodide of potassium, each, four parts; iodine and extract of opium, each, three parts. In confirmation of Dr. Bermond's views, M. Lemasson, one of the house pupils of the hospital St. Louis, has published

a number of cases, proving the efficacy of a combination of iodine and opium in the local treatment of scrofulous ulcerations. He concludes from his experience that the union of opiate preparations with iodine imparts to the latter, in many cases, new and valuable powers. One of the combinations which he employed consisted of *fifteen grains* of iodine, a *drachm* of iodide of potassium, and *two drachms* of Rousseau's laudanum, made up into an ointment with *two ounces* of fresh lard.

The protiodide and biniodide of mercury, besides being used in the form of ointment as already mentioned, are employed internally, especially in the treatment of scrofulous syphilis. They are both recognised as officinal in the different Pharmacopœias. (See *Hydrargyri Iodidum*, and *Hydrargyri Iodidum Rubrum*.) For the iodides of iron, lead, potassium, and sulphur, see *Ferri Iodidum*, *Plumbi Iodidum*, *Potassii Iodidum*, and *Sulphuris Iodidum*.

The results obtained by Dr. Lugol and others in the treatment of scrofulous diseases by the iodine preparations are so diversified, as to leave no doubt of their superiority over all other remedies in the same class of affections. A considerable number of practitioners in the United States have employed them in the same diseases with encouraging success; but at the same time, there has been a number of failures. To judge fairly, however, of Dr. Lugol's results, it is not sufficient for our practitioners to give iodine; but they should use it in the peculiar manner, and with the observance of all the rules, which are so fully laid down in the published memoirs of that physician. Reasoning on the subject, we can readily conceive that a dilute aqueous solution of iodine may act differently from the tincture; and that a therapeutical agent may be introduced gradually and imperceptibly into the current of the circulation in one form of administration, and thus be capable of producing important alterative effects; while in another, it may create irritation and even ulceration of the stomach without being absorbed, and thus prove mischievous. A case in point is furnished by mineral waters, which, though generally containing a minute portion of saline matter, often produce remedial effects which cannot be obtained by their constituents given in larger doses.

The views here presented are supported and extended by the observations and experiments of Dr. A. Buchanan, of Glasgow, who contends that iodine is divested of its irritant qualities in certain states of combination, in which it may be given in large doses without risk, and with the effect of pervading nearly all the secretions, and, under certain circumstances, even the blood. The combinations which he prefers, enumerated in the order of their relative efficacy, are iodide of starch, hydriodic acid, and iodide of potassium, the first and last of which he supposes to act as hydriodic acid, the iodine in them being, agreeably to his view, converted into that acid in the stomach and bowels. (See *Potassii Iodidum* in Part II., and *hydriodic acid* and *iodide of starch* in the Appendix.*)

The following is a list of all the officinal preparations of iodine, contained in the United States and British Pharmacopœias.

Iodine is officinal,—

I. IN SOLUTION IN ALCOHOL.

Tinctura Iodini, U. S.; Tinctura Iodinei, Ed.; Iodinii Tinctura, Dub.

* For further details the reader is referred to the work of Dr. Lugol, "*Sur l'Emploi de l'Iode dans les Maladies Scrofulieuses*," or its Translation, with valuable additions, by Dr. O'Shaughnessy, formerly of London, now of Calcutta. For notices of the iodides of ammonium and zinc, and of the iodohydrargyrate of potassium, see APPENDIX.

- II. IN SOLUTION IN ALCOHOL WITH IODIDE OF POTASSIUM.
Tinctura Iodini Composita, *U. S.*; Tinctura Iodinii Composita, *Lond.*
- III. IN THE FORM OF OINTMENT.
Unguentum Iodini, *U. S.*; Unguentum Iodinii, *Dub.*
- IV. IN THE FORM OF OINTMENT WITH IODIDE OF POTASSIUM.

IPECACUANHA. *U. S.*, *Lond.*, *Ed.*

Ipecacuanha.

“The root of *Cephaëlis Ipecacuanha*.” *U. S.*, *Ed.* “*Cephaëlis Ipecacuanha. Radix.*” *Lond.*

Off. Syn. CEPHAELIS IPECACUANHA. *Radix. Dub.*

Ipecacuanha, Fr.; Brechwurzel, *Ipecacuanha, Germ.*; *Ipecacuana, Ital.*, *Span.*

The term *ipecacuanha*, derived from the language of the aborigines of Brazil, has been applied to various emetic roots of South American origin. The British Colleges and our national Pharmacopœia recognise only that of the *Cephaëlis Ipecacuanha*; and no other is known by the name in the shops of this country. Our chief attention will, therefore, be confined to this root, and the plant which yields it; but as others are employed in South America, are occasionally exported, and may possibly reach our markets mingled with the genuine drug, we shall, in a note, give a succinct account of those which have attracted most notice.

The botanical character of the plant which yields genuine *ipecacuanha* was long unknown. Pison and Marcgrav, who were the first to treat of this medicine, in their work on the natural history of Brazil, published at Amsterdam, A.D. 1648, describe in general terms two plants; one producing a whitish root, distinguished by the name of white *ipecacuanha*, the other a brown root which answers in their description precisely to the officinal drug. But their account was not sufficiently definite to enable botanists to decide

upon the character of the plants; and much uncertainty existed on the subject. The medicine was generally thought to be derived from a species of *Viola*, which Linnæus designated by the title of *V. Ipecacuanha*. Opinion afterwards turned in favour of a plant sent to Linnæus by the celebrated Mutis from New Granada, as affording the ipecacuanha of that country and of Peru. This was described in the *Supplementum* of the younger Linnæus, A.D. 1781, under the name of *Psychotria emetica*, and was long erroneously considered as the source of the true ipecacuanha. Dr. Gomez, of Lisbon, was the first who accurately described and figured the genuine plant, which he had seen in Brazil, and specimens of which he took with him to Portugal; but Brotero, professor of botany at Coimbra, with whom he had left specimens, having drawn up a description, and had it inserted with a figure in the Linnean Transactions, without acknowledgment, enjoyed for a time the credit due to his fellow countryman. In the paper of Brotero the plant is named *Callicocca Ipecacuanha*; but the term *Callicocca* having been applied by Schreber, without sufficient reason, to a genus previously established and named, has been universally abandoned by botanists for the *Cephaelis* of Swartz; though this also, it appears, is a usurpation upon the previous rights of Aublet.

CEPHAELIS. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Rubiaceæ, *Juss.* Cinchonaceæ, *Lindley*.

Gen. Ch. Flowers in an involucred head. *Corolla* tubular. *Stigma* two-parted. *Berry* two-seeded. *Receptacle* chaffy. *Willd.*

Cephaelis Ipecacuanha. Richard, *Hist. Ipecac.* p. 21. t. i.; Martius, *Spec. Mat. Med. Brazil*, p. 4. t. i.—*Callicocca Ipecacuanha.* Brotero, *Linn. Trans.* vi. 137. This is a small shrubby plant, with a root from four to six inches long, about as thick as a goose-quill, marked with annular rugæ, simple or somewhat branched, descending obliquely into the ground, and here and there sending forth slender fibrils. The stem is two or three feet long; but being partly under ground, and often procumbent at the base, usually rises less than a foot in height. It is slender; in the lower portion leafless, smooth, brown or ash-coloured, and knotted, with radicles frequently proceeding from the knots; near the summit, pubescent, green, and furnished with leaves seldom exceeding six in number. These are opposite, petiolate, oblong obovate, acute, entire, from three to four inches long, from one to two broad, obscurely green and somewhat rough on their upper surface, pale, downy, and veined on the under. At the base of each pair of leaves are deciduous stipules, embracing the stem, membranous at their base, and separated above into numerous bristle-like divisions. The flowers are very small, white, and collected to the number of eight, twelve, or more, each accompanied with a green bracte, into a semi-globular head, supported upon a round, solitary, axillary footstalk, and embraced by a monophyllous involucre deeply divided into four, sometimes five or six obovate, pointed segments. The fruit is an ovate, obtuse berry, which is at first purple, but becomes almost black when ripe, and contains two small plano-convex seeds.

The plant is a native of Brazil, flourishing in moist, thick, and shady woods, and abounding most within the limits of the eighth and twentieth degrees of south latitude. According to Humboldt, it grows also in New Granada. It flowers in January and February, and ripens its fruit in May. The root is usually collected during the period of flowering, though equally good at other seasons. By this practice the plant is speedily extirpated in places where it is most eagerly sought. Were the seeds allowed to ripen, it would propagate itself rapidly, and thus maintain a constant supply. The

root is collected chiefly by the Indians, who prepare it by separating it from the stem, cleaning it, and hanging it up in bundles to dry in the sun. The Brazilian merchants carry on a very brisk trade in this drug. The chief places of export are Rio Janeiro, Bahia, and Pernambuco. It is brought to the United States in large bags or bales.

Genuine ipecacuanha is in pieces two or three lines in thickness, variously bent and contorted, simple or branched, consisting of an interior slender, light straw-coloured, ligneous cord, with a thick cortical covering, which presents on its surface a succession of circular, unequal, prominent rings or rugæ, separated by very narrow fissures frequently extending nearly down to the central fibre. This appearance of the surface has given rise to the term *annelé* or *annulated*, by which the true ipecacuanha is designated in the French works on pharmacy. The cortical part is hard, horny, and semitransparent, breaks with a resinous fracture, and easily separates from the tougher ligneous fibre, which possesses the medicinal virtues of the root in a much inferior degree. Attached to the root is frequently a smoother and more slender portion, which is the base of the stem, and should be separated before pulverization. Pereira has met, in the English market, with distinct bales composed of these fragments of stems, with occasionally portions of the root attached. Much stress has been laid in works on the materia medica upon the colour of the external surface of the ipecacuanha root, and diversity in this respect has even led to the formation of distinct varieties. Thus the epidermis is sometimes deep brown or even blackish, sometimes reddish-brown or reddish-gray, and sometimes light gray or ash-coloured. Hence the distinction into *brown*, *red*, and *gray ipecacuanha*. But these are all derived from the same plant, are essentially the same in properties and composition, and probably differ only in consequence of difference in age, or place of growth, or mode of desiccation. The colours in fact are often so intermingled, that it would be impossible to decide in which variety a particular specimen should be placed. The *brown* is the most abundant in the packages which reach our market. The *red*, besides the colour of its epidermis, presents a rosy tint when broken, and is said to be somewhat more bitter than the preceding variety. The *gray* is much lighter coloured externally, usually rather larger, with less prominent rings and wider fissures, and is still more decidedly bitter. We have seen, in this market, bales of a gray ipecacuanha, with very imperfectly developed rings, which were said to have come from Caracas. At present, however, this is very rare, if to be found at all. When the bark in either variety is opaque, with a dull amylaceous aspect, the root is less active as a medicine. As the woody part is nearly inert, and much more difficult of pulverization than the cortical, it often happens, that when a particular parcel of the root is powdered, the portion which remains last in the mortar possesses scarcely any emetic power; and care should be taken to provide against any defect from this cause. The colour of the powder is a light grayish-fawn.

Ipecacuanha has little smell in the aggregate state, but when powdered has a peculiar nauseous odour, which in some persons excites violent sneezing, in others dyspnœa resembling an attack of asthma. The taste is bitter, acrid, and very nauseous. Water and alcohol extract its virtues, which are injured by decoction. Its emetic property resides in a peculiar alkaline principle called *emetin*, or more properly *emetia*, discovered by Pelletier in the year 1817. The cortical portion of the brown ipecacuanha, analyzed by this chemist under the erroneous name of *Psychotria emetica*, yielded in the hundred parts, 16 of an impure salt of emetia, which was at first considered the pure emetic principle, 2 of an odorous fatty matter, 6 of wax,

10 of gum, 42 of starch, 20 of lignin, with 4 parts loss. The woody fibre was found to contain only 1.15 per cent. of the impure emetia. M. A. Richard obtained, from the cortical part, the same proportion of emetia as found by Pelletier, but detected some principles not noticed by that chemist, among which were traces of gallic acid. The bark of the red ipecacuanha was found by Pelletier to contain but fourteen per cent. of the impure emetia. The *gray* variety has not been analyzed. One hundred parts of good ipecacuanha contain about 80 of cortical and 20 of ligneous matter.

Emetia when perfectly pure is whitish, inodorous, slightly bitter, pulverulent, unalterable in the air, very fusible, sparingly soluble in cold water and ether, more soluble in hot water, and very soluble in alcohol; is not reddened by nitric acid; forms crystallizable salts with the mineral acids and acetic acid; is precipitated by gallic and tannic acids from its solutions; and contains nitrogen among its ingredients. It is, however, very difficult to procure it in this state of purity, and the proportion afforded by the root is exceedingly small. As originally obtained it was very impure, probably in the condition of a salt, and in this state is directed by the French Codex. *Impure emetia* is in transparent scales of a brownish-red colour, almost inodorous, of a bitterish acrid taste, deliquescent, very soluble in water and alcohol, insoluble in ether, precipitated from its solutions by gallic acid and the acetates of lead, but not by tartar emetic or the salts of iron. The Codex directs it to be prepared by evaporating a filtered aqueous solution of an alcoholic extract of ipecacuanha. According to the original method, it was obtained by treating powdered ipecacuanha with ether to remove the fatty matter, exhausting the residue with alcohol, evaporating the alcoholic solution to dryness, and subjecting the extract to the action of cold water, which dissolves the emetia with some free acid, and leaves the wax and other matters. To separate the acid, the watery solution is treated with carbonate of magnesia, filtered, and then evaporated. If pure *emetia* is required, magnesia is used instead of the carbonate. The salt is thus decomposed, and the organic alkali, being insoluble, is precipitated with the excess of the earth. The precipitate is washed with cold water, and digested in alcohol, which dissolves the *emetia*; the alcoholic solution is then evaporated, the residue redissolved in a dilute acid, and the alkali again precipitated by a salifiable base. To deprive it of colour it is necessary to employ animal charcoal. Berzelius has obtained emetia by treating the powdered root with very dilute sulphuric acid, precipitating with magnesia, and treating the precipitate in the manner above directed. Pure emetia has at least three times the strength of the impure.*

* NON-OFFICIAL IPECACUANHAS.—When ipecacuanha began to be popular in Europe, the roots of several other plants were imported and confounded with the genuine, and the name came at length to be applied to almost all emetic roots derived from America. Several of these are still occasionally met with, and retain the name originally applied to them. The two most worthy of notice are the ipecacuanha of New Granada and Peru, and the white ipecacuanha of Brazil. On each of these we shall offer a few remarks.

1. *Peruvian Ipecacuanha. Striated Ipecacuanha. Black Ipecacuanha.*—This is the root of the *Psychotria emetica*, formerly supposed to produce the genuine Brazilian ipecacuanha. The plant, like the *Cephaelis*, belongs to the class and order Pentandria Monogynia, and to the natural order Rubiaceæ of Jussieu. A description of it sent by Mutis was published by Linnæus the younger in his supplement. It has since been described in the *Plant. Æquin.* of Humb. and Bonpl.; and has been figured by A. Richard in his History of the Ipecacuanhas, and by Hayne in the eighth volume of his Medical Botany published at Berlin. It is a small shrub, with a stem twelve or eighteen inches high, simple, erect, round, slightly pubescent, and furnished with opposite, oblong lanceolate, pointed leaves, narrowed at their base into a short petiole, and accompanied with pointed stipules. The flowers are small, white, and supported in small clusters towards the end

Medical Properties and Uses. Ipecacuanha is in large doses emetic, in smaller, diaphoretic and expectorant, and in still smaller, stimulant to the stomach, exciting appetite and facilitating digestion. In quantities insufficient to vomit, it produces nausea and frequently acts upon the bowels. As

of an axillary peduncle. The plant flourishes in Peru and New Granada, and was seen by Humboldt and Bonpland growing in abundance near the river Magdalena. The dried root is said to be exported from Carthagena.

It is cylindrical, somewhat thicker than the root of the *Cephaelis*, usually simple, but sometimes branched, not much contorted, wrinkled longitudinally, presenting here and there deep circular intersections, but without the annular rugæ of the true ipecacuanha. The longitudinal direction of the wrinkles has given origin to the name of *striated ipecacuanha*, by which it is known in French Pharmacy. It consists of an internal woody cord and an external cortical portion; but the former is usually larger in proportion to the latter than in the root of the *Cephaelis*. The bark is soft and easily cut with a knife, and when broken exhibits a brown slightly resinous fracture. The epidermis is of a dull reddish-gray colour, which darkens with age and exposure, and ultimately becomes almost black. Hence the root has sometimes been called *black ipecacuanha*. The ligneous portion is yellowish, and perforated with numerous small holes visible by the microscope. The Peruvian ipecacuanha is nearly inodorous, and has a flat taste, neither bitter nor acrid. Out of 100 parts Pelletier obtained 9 of impure emetia, 12 of fatty matter, with an abundance of starch, besides gum and lignin. The dose, as an emetic, is from two scruples to a drachm.

2. *White Ipecacuanha. Amylaceous Ipecacuanha. Undulated Ipecacuanha.*—This variety was noticed in the work of Pison, but the vegetable which produced it was not satisfactorily ascertained till a recent date. Gomez, indeed, in the memoir which he published at Lisbon, A.D. 1801, gave a figure and description of the plant; but the memoir was not generally known, and botanists remained uncertain upon the subject. By the travels of M. Saint-Hilaire and Dr. Martius in Brazil, more precise information has been obtained; and the white ipecacuanha is now confidently referred to different species of *Richardsonia*, the *Richardia* of Linnæus. The *R. scabra*, or *R. brasiliensis* of Gomez, and the *R. emetica* are particularly indicated by Martius. For the root usually called *white ipecacuanha*, Guibourt has proposed the name of *undulated ipecacuanha*, derived from the peculiar character of the surface, which presents indentations or concavities on one side, corresponding with prominences or convexities on the other, so as to give a wavy appearance to the root. It differs little in size from the genuine; is of a whitish-gray colour externally; and when broken presents a dull white farinaceous fracture, offering, by the light of the sun, shining points, which are nothing more than small grains of fecula. Like the other varieties it has a woody centre. It is inodorous and insipid, and contains, according to Pelletier, a very large proportion of starch, with only six per cent. of impure emetia, and two of fatty matter. Richard found only 3.5 parts of emetia in the hundred. It is said to be sometimes mixed with the genuine ipecacuanha; but we have discovered none in the bales which we have examined.

According to Martius, different species of *Ionidium* (*Viola*, Linn.) produce also what is called *white ipecacuanha*. The roots of all the species of *Ionidium* possess emetic or purgative properties, and some of them have been reported to be equal to the genuine ipecacuanha. The root of the *I. ipecacuanha* is described by Guibourt as being six or seven inches long, as thick as a quill, somewhat tortuous, and exhibiting at the points of flexion semicircular fissures, which give it some resemblance to the root of the *Cephaelis*. It is often bifurcated at both extremities, and terminates at top in a great number of small ligneous stalks. It is wrinkled longitudinally, and of a light yellowish-gray colour. The bark is thin, and the interior ligneous portion very thick. The root has little taste or smell. According to Pelletier, it contains in 100 parts 5 of an emetic substance, 35 of gum, 1 of azotized matter, and 37 of lignin. (*Hist. Abreg. des Drogues Simples*, i. 514.)

The root of a species of *Ionidium* growing in Quito has attracted some attention as a remedy in elephantiasis, under the South American name of *cuichunchulli*. The plant, being considered an undescribed species by Dr. Bancroft, was named by him *I. Marcucci*; but Sir W. Hooker found the specimen, received from Dr. Bancroft, to be identical with the *I. parviflorum* of Ventenat. Lindley thinks a specimen he received under the same name from Quito, to be the *I. microphyllum* of Humboldt. If useful in elephantiasis, it is so probably by its emeto-purgative action. (See *Am. Journ. of Pharm.* vii. 186.)*

* See a paper on ipecacuanha by R. E. Griffith, M. D., in the *Journ. of the Phil. Col. of Pharm.* Vol. 3. p. 181, for a more extended account of the roots which have been used under the name of ipecacuanha.

an emetic it is mild but tolerably certain in its operation, and, being usually thrown from the stomach by one or two efforts, is less apt to produce dangerous effects when taken in an overdose than some other substances of the same class. It is also recommended by the absence of corrosive and narcotic properties.

It was employed as an emetic by the natives of Brazil, when that country was first settled by the Portuguese; but, though described in the work of Pison, it was not known in Europe till the year 1672, and did not come into use till some years afterwards. John Helvetius, grandfather of the celebrated author of that name, having been associated with a merchant who had imported a large quantity of ipecacuanha into Paris, employed it as a secret remedy, and with so much success in dysentery and other bowel affections, that general attention was attracted to it; and the fortunate physician received from Louis XIV. a large sum of money, and public honours, on the sole condition that he should make the remedy public. From this period it has maintained its standing among the most useful articles of the materia medica.

As an emetic it is peculiarly adapted by its mildness and efficiency to all cases in which the object is merely to evacuate the stomach, or a gentle impression only is desired; and in most other cases in which emetics are indicated, it may be advantageously combined with the more energetic medicines, the action of which it renders safer by insuring their discharge. It is especially useful where narcotic poisons have been swallowed, as under these circumstances it may be given in almost indefinite doses, with little comparative risk of injury to the patient. In dysentery it has been supposed to exercise peculiar powers; but is at present less used than formerly in doses sufficient to excite vomiting. As a nauseating remedy it is used in asthma, hooping cough, and the hemorrhages; as a diaphoretic, combined with opium, in a wide circle of diseases. (See *Pulvis Ipecacuanhæ et Opii*.) Its expectorant properties render it beneficial in catarrhal and other pulmonary affections. It has been given also, with supposed advantage, in very minute doses, in dyspeptic cases, and in chronic disease of the gastrointestinal mucous membrane.

Ipecacuanha is most conveniently administered as an emetic in the form of powder suspended in water. The dose is about twenty grains, repeated if necessary at intervals of twenty minutes till it operates. In some individuals much smaller quantities prove emetic, and we know one person who is generally vomited by the fraction of a grain. The operation of the medicine may be facilitated, and rendered milder, by copious draughts of warm water, or warm chamomile tea. An infusion in boiling water, in the proportion of two drachms of the powder to six fluidounces of menstruum, may be given in the dose of a fluidounce repeated as in the former case. With a view to the production of nausea, the dose in substance may be two grains, given more or less frequently according to circumstances. As a diaphoretic it may be given in the quantity of a grain; as an alterative, in diseases of the stomach and bowels, of a quarter or half a grain two or three times a day.

Emetia has been used on the continent of Europe as a substitute, but with no great advantage. Its operation on the stomach is apt to be more violent and continued than that of ipecacuanha itself; and, if given in overdoses, it may produce dangerous and even fatal consequences. From the experiments of Magendie, it appears to have a peculiar direction to the mucous membranes of the alimentary canal and the bronchial tubes. Ten grains of the impure alkali, administered to dogs, were generally found to destroy life in twenty-four hours, and the mucous membranes mentioned were observed to be inflamed throughout their whole extent. The same

result took place when emetia was injected into the veins, or absorbed from any part of the body. The dose of impure emetia is about a grain and a half, of the pure not more than half a grain, repeated at proper intervals till it vomits. In proportional doses, it may be applied to the other purposes for which ipecacuanha is used. It will excite vomiting when applied to a blistered surface after the removal of the cuticle. Magendie found that dogs slept much after being vomited with emetia, and concluded that the medicine was narcotic; but other emetic medicines produce the same effect, which is to be ascribed rather to exhaustion than to any direct operation on the brain.

Dr. Turnbull recommends the external use of ipecacuanha as a counter-irritant. An ointment made with one part of the powder, one of olive oil, and two of lard, rubbed once or twice a day, for a few minutes, upon the skin, produces a copious eruption, which continues out for many days, without pain or ulceration. (*London Lancet*, May, 1842.)

IRIS FLORENTINA. *U. S. Secondary.*

Florentine Orris.

“The rhizoma of *Iris Florentina*.” *U. S.*

Iris de Florence, *Fr.*; *Florentinische Viole*, *Wurzel*, *Germ.*; *Ireos*, *Ital.*; *Lirio Florentina*, *Span.*

IRIS. *Sex. Syst.* Triandria Monogynia.—*Nat. Ord.* Iridaceæ.

Gen. Ch. Corolla six-parted; the alternate segment reflected. *Stigmas* petal-shaped. *Willd.*

In all the species belonging to this genus, so far as examined, the roots are more or less acrid, and possessed of cathartic and emetic properties. In Europe, the *I. fetidissima*, *I. Florentina*, *I. Germanica*, *I. pseudo-acorus*, and *I. tuberosa* have at various times been admitted into use. Of these the *I. Florentina* is the only one official in this country.

Iris Florentina. Willd. *Sp. Plant.* i. 226; Woodv. *Med. Bot.* p. 776. t. 262. The root (rhizoma) of the Florentine Iris is perennial, horizontal, fleshy, fibrous, and covered with a brown epidermis. The leaves spring directly from the root, are sword-shaped, pointed, nerved, and shorter than the stem, which rises from the midst of them more than a foot in height, round, smooth, jointed, and bearing commonly two large white or bluish-white terminal flowers. The calyx is a spathe with two valves. The corolla divides into six segments or petals, of which three stand erect, and the remaining three are bent backward, and bearded within at their base with yellow-tipped white hairs. The fruit is a three-celled capsule, containing numerous seeds.

This plant is a native of Italy, and other parts of the South of Europe. The root, which is the official portion, is dug up in spring, and prepared for the market by the removal of its cuticle and fibres. It is brought from Leghorn in large casks.

Properties. Florentine orris is in pieces of various form and size, often branched, usually about as thick as the thumb, knotty, flattened, white, heavy, of a rough though not fibrous fracture, a pleasant odour resembling that of the violet, and a bitterish acrid taste. The acrimony is greater in the recent than in the dried root; but the peculiar smell is more decidedly

developed in the latter. The pieces are brittle and easily powdered, and the powder is of a dirty white colour. Vogel obtained from Florentine orris, gum, a brown extractive, fecula, a bitter and acrid fixed oil or soft resin, a volatile crystallizable oil, and vegetable fibre.

Medical Properties. This medicine is cathartic, and in large doses emetic, and was formerly employed to a considerable extent on the continent of Europe. It is said also to be diuretic, and to have proved useful in dropsies. At present it is highly valued for its pleasant odour. It is occasionally chewed to conceal an offensive breath, and enters into the composition of numerous tooth-powders. In the form of small round balls, about the size of a pea, it is much used by the French for maintaining the discharge from issues, a purpose to which it is adapted not only by its odour, but also by the slight degree of acrimony which it retains in its dried state, and by the property of swelling very much by the absorption of moisture. W.

IRIS VERSICOLOR. U.S. Secondary.

Blue Flag.

“The rhizoma of *Iris versicolor.*” U.S.

IRIS. See IRIS FLORENTINA.

Iris versicolor. Willd. *Sp. Plant.* i. 233; Bigelow, *Am. Med. Bot.* i. 155. This indigenous species of *Iris* has a perennial, fleshy, horizontal, fibrous root or rhizoma, and a stem two or three feet high, round on one side, acute on the other, and frequently branching. The leaves are sheathing at the base, sword-shaped, and striated. The flowers are from two to six in number, and are usually blue or purple, though varying much in colour. The capsule has three valves, is divided into three cells, and when mature is oblong, three-sided, with obtuse angles, and contains numerous flat seeds.

The blue flag is found in all parts of the United States, flourishing in low wet places, in meadows, and on the borders of swamps, which it serves to adorn with its large and beautiful flowers. These make their appearance in June. The root is the medicinal portion. The flowers afford a fine blue infusion, which serves as a test of acids and alkalies.

The recent root is without odour, and has a nauseous, extremely acrid taste, which is imparted to water by decoction, and still more perfectly to alcohol. The acrimony as well as medicinal activity is impaired by age.

The blue flag possesses the cathartic, emetic, and diuretic properties common to most of the species of this genus. It is said by Mr. Bartram to be held in much esteem by the Southern Indians; and Dr. Bigelow informs us that he has found it efficacious as a purgative, though inconvenient from the distressing nausea and prostration which it is apt to occasion. Dr. Macbride of Carolina found it useful in dropsy. It is, however, very little employed by the profession at large, and is seldom if ever kept in the shops. It may be given in substance, decoction, or tincture. The dose of the dried root is from ten to twenty grains. W.

JALAPA. U.S., Lond., Ed., Dub.

Jalap.

“The root of *Ipomæa Jalapa*, (Coxe, *Am. Journ. of Med. Sciences*).” U.S. “*Ipomæa Jalapa. Radix.*” Lond. “Root of *Ipomæa Purga*, (*Nees von Esenbeck*).” Ed. “*Convolvulus Jalapa. Radix.*” Dub.

Jalap, *Fr.*; Jalappen-Wurzel, *Germ*; Sciarappa, *Ital.*; Jalapa, *Span.*

It is only within a few years that the precise botanical origin of jalap has been known. It was at first ascribed by Linnæus to a *Mirabilis*, but afterwards to a new species of *Convolvulus*, to which he gave the name of *C. Jalapa*. The correctness of the latter reference was generally admitted; and, as the *Ipomæa macrorhiza* of Michaux, growing in Florida and Georgia, was believed to be identical with the *C. Jalapa* of Linn., it was thought that this valuable drug, which had been obtained exclusively from Mexico, might be collected within the limits of the United States. But the error of this opinion was soon demonstrated; and botanists now universally concur in the belief, that jalap is the product of a plant first made known to the scientific world by Dr. John R. Coxe of Philadelphia, and described by Mr. Nuttall under the name of *Ipomæa Jalapa*. When this Dispensatory was first published, opinion in relation to the botanical history of the drug was unsettled, and it was deemed proper to enter at some length into the consideration of the subject; but the subsequent general admission of the views then advocated renders an equal degree of minuteness now unnecessary. It is sufficient to state, that Dr. Coxe received living roots of jalap from Mexico in the year 1827, and succeeded in producing a perfect flowering plant, of which a description, by Mr. Nuttall, was published in the *Am. Journ. of Medical Sciences* for January, 1830; that the same plant was afterwards cultivated in France and Germany from roots transmitted to those countries from the jalap region of Mexico; and that one of the authors of this work has produced, from roots obtained in the vicinity of Xalapa, and sent to him by Dr. Marmaduke Burrough, then United States consul at Vera Cruz, luxuriant plants, which he was enabled to compare with others descended from the plant of Dr. Coxe, and found to be identical with them.* In the United States, London, and Edinburgh Pharmacopœias, this origin of jalap is now admitted; but the London College has quoted as authority for their *Ipomæa Jalapa* an unpublished manuscript by Don, and the Edinburgh College has adopted Hayne's and Wenderoth's name of *I. Purga*, thus overlooking the prior claims of the American authorities.

IPOMÆA. Sex. Syst. Pentandria Monogynia.—*Nat. Ord.* Convolvulacæ.

Gen. Ch. Sepals five. Corolla campanulate. Stamens included. Style one. Stigma two-lobed; the lobes capitate. Ovary two-celled; cells two-seeded. Capsule two-celled. *Lindley.*

Ipomæa Jalapa. Nuttall, *Am. Journ. Med. Sciences*, v. 300. *Ipomæa Purga.* Hayne, *Darstel. und Beschreib. &c.* xii. 33 and 34; Lindley, *Flor. Med.* 396. The root of this plant is a roundish somewhat pear-shaped tuber, externally blackish, internally white, with long fibres proceeding from its lower part as well as from the upper root-stalks. A tuber produced by Dr. Coxe was, in its third year, between two and three inches in diameter. The stem is round, smooth, much disposed to twist, and rises to a considerable height upon neighbouring objects, about which it twines. The leaves are heart-shaped, entire, smooth, pointed, deeply sinuated at the base, prominently veined on their under surface, and supported upon long footstalks. The lower leaves are nearly hastate, or with diverging angular points. The flowers, which are large and of a lilac-purple colour, stand upon peduncles about as long as the petioles. Each peduncle supports two,

* They who may wish to investigate more fully the botanical history of jalap are referred to former editions of this Dispensatory, to a paper by Dr. John Redman Coxe in the *American Journal of the Medical Sciences* (vol. v. p. 300), to another paper by Mr. Daniel B. Smith, in the *Journal of the Philadelphia College of Pharmacy* (vol. ii. p. 22), and to Dr. Christison's Dispensatory.

or more rarely three flowers. The calyx is without bractes, five-leaved, obtuse, with two of the divisions external. The corolla is funnel-form. The stamens are five in number, with oblong, white, somewhat exserted anthers. The stigma is simple and capitate. The above description is taken from that drawn up by Mr. Nuttall, and published in Dr. Coxe's paper in the American Journal of the Medical Sciences.

The jalap plant is a native of Mexico, and derived its name from the city of Xalapa, in the state of Vera Cruz, in the neighbourhood of which it grows, at a height of about 6000 feet above the ocean. It might probably be cultivated in the southern section of the United States. The drug is brought from the port of Vera Cruz in bags containing usually between one hundred and two hundred pounds.

Properties. The tuber comes either whole, or divided longitudinally into two parts, or in transverse circular slices. The entire tubers are irregularly roundish, or ovate and pointed, or pear-shaped, usually much smaller than the fist, and marked with circular or vertical incisions, made to facilitate their drying. In this state, the root is preferred, as it is less apt to be defective, and is more easily distinguished from the adulterations than when sliced. A much larger proportion comes in this shape than formerly, indicating a greater scarcity of the older roots, which it is necessary to slice in order to dry them properly. The tuber is heavy, compact, hard, brittle, with a shining undulated fracture, exhibiting numerous resinous points, distinctly visible with the microscope. It is externally brown and wrinkled, internally of a grayish colour, diversified by concentric darker circles, in which the matter is denser and harder than in the intervening spaces. Jalap is always kept in the shops in the state of powder, which is of a yellowish-gray colour, and when inhaled irritates the nostrils and throat, and provokes sneezing and coughing. The odour of the root, when cut or broken, is heavy, sweetish, and rather nauseous; the taste is sweetish, somewhat acrid, and disagreeable. It yields its active properties partly to water, partly to alcohol, and completely to diluted alcohol. M. Cadet de Gassicourt obtained from 500 parts of jalap, 24 of water, 50 of resin, 220 of gummy extract, 12·5 of fecula, 12·5 of albumen, 145 of lignin, 16·3 of saline matters, 2·7 of silica, with a loss of 17 parts. The resin of jalap consists of two portions, one of which, amounting to seven parts out of ten, is hard and insoluble in ether, the other is soft and soluble in that menstruum. The proportion of resin to the other ingredients of the root varies considerably in different specimens. According to Gerber, the root contains 7·8 per cent. of hard resin, 3·2 of soft resin, 17·9 of extractive, 14·5 of gummy extract, 8·2 of a colouring substance which becomes red under the influence of the alkaline carbonates, 1·9 of uncrystallizable sugar, 15·6 of gum mixed with some saline matters, 3·2 of bassorin, 3·9 of albumen, 6·0 of starch, 8·2 of lignin, with some water, and various salts. For the method of obtaining the resin of jalap pure, see *Extractum sive Resina Jalapæ*.

Jalap is apt to be attacked by worms, which, however, are said to devour the amylaceous or softer parts, and to leave the resin, so that the worm-eaten drug is more powerfully purgative than that which is sound. Thus, out of 397 parts of the former, M. Henry obtained 72 parts of resin, while from an equal quantity of the latter he procured only 48 parts. Hence worm-eaten jalap should be employed for obtaining the resin, but should not be pulverized, as it would afford a powder of more than the proper strength. The drug is also liable to various adulterations, or fraudulent substitutions, which, however, can usually be detected without difficulty. Those which

have attracted particular attention are mentioned in a note below.* Jalap should be rejected when it is light, of a whitish colour internally, of a dull fracture, spongy, or friable.

Medical Properties and Uses. Jalap is an active cathartic, operating

* *Adulterations, &c.* Jalap is said to be sometimes adulterated with *bryony root*; but no instance of the kind has come under our notice; and the two drugs are so widely different that the fraud would be instantly detected. (See *Bryony* in the Appendix.) It is probable, however, that the adulteration which has been considered as bryony root, is the *mechoacan*, which in Europe is sometimes called American bryony, and was formerly erroneously supposed to be derived from a species of *Bryonia*. The *mechoacan* is a product of Mexico, which was taken to Europe even before the introduction of jalap. The plant which produces it has been conjectured to be the *Ipomœa macrorrhiza* of Michaux, which is believed to grow in Mexico near Vera Cruz, as well as in our Southern States, and the root of which, when of full size, is said to weigh from fifty to sixty pounds, and, according to Dr. Baldwin, has little or no purgative power. But this origin is altogether uncertain. Mechoacan is in circular slices, or fragments of various shape, white and farinaceous within, and, as found in European markets, generally destitute of bark, of which, however, portions of a yellowish colour sometimes continue to adhere. The larger pieces are sometimes marked with faint concentric striæ; and, upon the exterior surface, when any portion of this remains, are brown spots and ligneous points left by the radicles which have been removed. (*Guibourt*.) Though tasteless when first taken into the mouth, it becomes after a time slightly acrid. It is very feebly purgative. We have seen flat circular pieces of root, mixed with jalap, altogether answering this description, except that the cortical portion still remained, between which and the amylaceous parenchyma there was a very evident line of division.

A drug formerly known in our markets as spurious jalap, sometimes comes mingled with the genuine, and has been imported unmixed, in mistake for that root. It is probably the same with that referred to by French writers as the product of a plant denominated *male jalap* in Mexico, and named by M. Ledanois *Convolvulus Orizabensis*, from the city of Orizaba, in the neighbourhood of which it grows abundantly. In the shops of Paris the drug is called *light jalap*, and, in the last edition of *Guibourt's Histoire des Drogues*, is described under the title of *fusiform jalap*. A description of it was first published in this country by Mr. D. B. Smith, in a valuable paper upon the *Ipomœa Jalapa*, in the *Am. Journ. of Pharm.* vol. ii. p. 22. For an account of the plant, the reader is referred to the same Journal, vol. x. p. 224. The recent root is large, spindle-shaped, sometimes as much as twenty inches in length, branched at its lower extremity, of a yellow colour on its outer surface, and white and milky within. The drug, as described by *Guibourt*, is in circular pieces, two or three inches in diameter, or in longer and more slender sections. As we have seen it, the shape of the pieces is often such as to indicate that the root was sliced transversely, and each circular slice divided into quarters. The horizontal cut surface is dark from exposure, unequal from the greater shrinking in the drying process of some parts than others, and presents the extremities of numerous fibres, which are often concentrically arranged, and run in the longitudinal direction of the root. Internally the colour is whitish, and the texture, though much less compact than that of jalap, is sometimes almost ligneous. The taste is at first slight, but after a time becomes somewhat acrid and nauseous. The dried root of the *Convolvulus Orizabensis* or *male jalap*, analyzed by M. Ledanois, yielded in 1000 parts, 80 of resin, 256 of gummy extract, 32 of fecula, 24 of albumen, and 580 of lignin. From experiments made with it in Paris, it appears to have cathartic properties similar to those of the true jalap, but to be considerably more feeble, requiring to be given in a dose of from thirty to sixty grains in order to operate effectively. The proportion of resin, which in both is the most active purgative principle, is considerably less in the male jalap, while that of lignin, which is wholly inert, is about double. (*Journ. de Pharm.* xxiv. 166; also *Am. Journ. of Pharm.* x. 223.)

A false jalap has recently been brought into the United States, different from any thing hitherto seen in our market. It is said to have been imported from Mexico into New York in considerable quantities, and offered for sale under the name of *overgrown jalap*. A specimen brought to Philadelphia, and examined by a Committee of the College of Pharmacy, presents the following characters. It is in light, entire or vertically sliced tubers, of different form and magnitude, spindle-shaped, ovate, and kidney-form, some as much as six inches long and three thick, others much smaller, externally somewhat wrinkled, with broad flattish light-brown ridges and shallow darker furrows, internally grayish-white, with distant darker concentric circles, sometimes uniformly amylaceous, of

briskly and sometimes painfully upon the bowels, and producing copious watery stools. The aqueous extract purges moderately, without much griping, and is said to increase the flow of urine. The portion not taken up by water gripes severely. The watery extract obtained from jalap previously exhausted by rectified spirit, is said to have no cathartic effect, but to operate powerfully by urine. (*Duncan.*) The alcoholic extract, usually called resin of jalap, purges actively, and often produces severe griping. From these facts it appears, that the virtues of this cathartic do not depend exclusively upon any one principle. Jalap was introduced into Europe in the latter part of the sixteenth, or beginning of the seventeenth century, and now ranks among the purgative medicines most extensively employed. It is applicable to most cases in which an active cathartic is required, and from its hydragogue powers is especially adapted to the treatment of dropsy. It is generally given in connection with other medicines which assist or qualify its operation. In dropsical complaints it is usually combined with the bitartrate of potassa; and the same mixture is much employed in the treatment of the hip disease, and scrofulous affections of other joints. With calomel it forms a cathartic compound, which has long been highly popular in the United States in bilious fever, and other complaints attended with congestion of the liver or portal circle. In overdoses it may produce dangerous hypercatharsis. It is said to purge when applied to a wound.

The dose of jalap in powder is from fifteen to thirty grains; of the resin or alcoholic extract, which is much used on the continent of Europe, and is now directed by the Edinburgh College, from four to eight grains. The latter is usually given rubbed up with sugar, or in emulsion, by which its tendency to irritate painfully the mucous membrane of the bowels is thought to be in some measure obviated. The extract of the United States and London Pharmacopœias is preferable to the alcoholic, as it more completely represents the jalap itself. The dose of calomel and jalap is ten grains of each, that of the bitartrate of potassa and jalap, two drachms of the former and ten or fifteen grains of the latter.

a dull rough fracture, a loose texture, a slight, peculiar, and sweetish odour, and a feeble jalap-like taste. The powder is of a light-gray colour, and does not irritate the nostrils or throat during pulverization. The root differs from Mechoacan by the absence of the marks of radical fibres, and from male jalap by the want of a fibrous structure. It yielded by analysis, in 100 parts, 3 of a soft and 4 of a hard and brittle resin, 17 of gummy extractive, 28 of starch and inulin, 10 of gum and albumen, 23.2 of lignin, and 14.8 of saccharine matter and salts of lime, including loss. In doses of from fifteen to twenty grains it produced no effect on the system, and cannot, therefore, be used as jalap. A similar root has recently been described by Guibourt in the *Journal de Chimie Medicale*, by the name of *rose-scented jalap*. It was taken to France from Mexico mixed with genuine jalap. It proved equally inefficacious as a purgative, and probably had the same origin. This spurious drug is probably the product of a *Convolvulus* or *Ipomœa*. See a report by Messrs. Duhamel, Ellis, and Ecky in the *American Journal of Pharmacy*, xiv. 289.

Several products of the *Juglans regia*, or common European walnut, are used medicinally in Europe. The hull of the fruit has been employed as a vermifuge from the times of Hippocrates, and has been recommended in syphilis and old ulcers. The expressed oil of the fruit is deemed by some practitioners efficacious against the tape-worm, and is also used as a laxative injection. The *leaves*, long occasionally employed for various purposes both in regular and domestic practice, have recently been found, by professor Négrier, of Angers, in the highest degree efficacious in scrofula. He gave to children a tea-cupful of a pretty strong infusion, or six grains of the aqueous extract, or an equivalent dose of a syrup prepared from the extract, two, three, or four times a day; and at the same time applied a strong decoction to the ulcers, and as a collyrium when the eyes were diseased. No injury was ever experienced from a long-continued use of the remedy. It appears to act as a moderately aromatic bitter and astringent. (*Archives Gen. 3^e Serie*, x. 399 and xi. 41.) The leaves of our *J. nigra* or common black walnut, or those of the *J. cinerea*, which is the only officinal species, would probably answer as good a purpose.

Juglans cinerea. Willd. *Sp. Plant.* iv. 456; Bigelow, *Am. Med. Bot.* ii. 115.—*J. cathartica*. Michaux, *N. Am. Sylva*. i. 160. This is an indigenous forest tree, known in different sections of the country by the various names of *butternut*, *oilnut*, and *white walnut*. In favourable situations it attains a great size, rising sometimes fifty feet in height, with a trunk three or four feet in diameter at the distance of five feet from the ground. The stem divides, at a small distance from the ground, into numerous nearly horizontal branches, which spread widely, and form a large tufted head, giving to the tree a peculiar aspect. The young branches are smooth and of a grayish colour, which has given origin to the specific name of the plant. The leaves are very long, and consist of seven or eight pairs of sessile leaflets, and a single petiolate leaflet at the extremity. These are two or three inches in length, oblong-lanceolate, rounded at the base, acuminate, finely serrate, and somewhat downy. The male and female flowers are distinct upon the same tree. The former are in large aments, four or five inches long, hanging down from the sides of the shoots of the preceding year's growth near their extremity. The fertile flowers are at the end of the shoots of the same spring. The germ is surmounted by two large, feathery, rose-coloured stigmas. The fruit is sometimes single, suspended by a thin pliable peduncle; sometimes several are attached to the sides and extremity of the same peduncle. The drupe is oblong-oval, with a terminal projection, hairy, viscid, green in the immature state, but brown when ripe. It contains a hard, dark-coloured, oblong, pointed nut, with a rough deeply and irregularly furrowed surface. The kernel is thick, oily, and pleasant to the taste.

The butternut grows in Upper and Lower Canada, and throughout the

whole northern, eastern, and western sections of the United States. In the Middle States, the flowers appear in May, and the fruit ripens in September. The tree, if pierced immediately before the leaves unfold, yields a richly saccharine juice, from which sugar may be obtained nearly if not quite equal to that from the sugar-maple. The wood, though neither strong nor compact, is useful for some purposes on account of its durability, and exemption from the attacks of worms. The fruit, when half grown, is sometimes made into pickles, and when ripe, affords, in its kernel, a grateful article of food. The bark is used for dyeing wool a dark-brown colour, though inferior for this purpose to that of the black walnut. It is said, when applied to the skin, to have a rubefacient effect. The inner bark is the medicinal portion, and that of the root, being considered most efficient, is directed by the national Pharmacopœia. It should be collected in May or June.

On the living tree, the inner bark when first uncovered is of a pure white, which becomes immediately on exposure a beautiful lemon colour, and ultimately changes to deep brown. It has a fibrous texture, a feeble odour, and a peculiar, bitter, somewhat acrid taste. Its medical virtues are entirely extracted by boiling water. Dr. Bigelow could detect no resin among its constituents; and the presence of tannin was not evinced by the test of gelatin, though a brownish-black colour was produced by the sulphate of iron.

Medical Properties and Uses. Butternut is a mild cathartic, operating without pain or irritation, and resembling rhubarb in the property of evacuating without debilitating the alimentary canal. It was much employed during our revolutionary war by Dr. Rush and other physicians attached to the army, and was highly esteemed. It is especially applicable to cases of habitual costiveness and other bowel affections, particularly dysentery, in which it has acquired considerable reputation. In connexion with calomel it becomes more active, and is sometimes used in our intermittent and remittent fevers, and other complaints attended with congestion of the abdominal viscera. It is given in the form of decoction or extract, never in substance. The extract is officinal, and is almost always preferred. The dose of it is from twenty to thirty grains as a purge, from five to ten grains as a laxative.

Juniperus communis. *Willd. Sp. Plant.* iv. 853; *Woodv. Med. Bot.* p. 13. t. 6. This is an erect evergreen shrub, usually small, but sometimes attaining a height of twelve or fifteen feet, with numerous very close

branches. The leaves are narrow, longer than the fruit, entire, sharply pointed, channeled, of a deep green colour, somewhat glaucous on their upper surface, spreading, and attached to the stem or branches in threes, in a verticillate manner. The flowers are diœcious and disposed in small, ovate, axillary, sessile, solitary aments. The fruit is formed of the fleshy coalescing scales of the ament, and contains three angular seeds.

The common juniper is a native of Europe; but has been introduced into this country, in some parts of which it has become naturalized. It is not uncommon in the neighbourhood of Philadelphia. The plant described in Bigelow's American Medical Botany under the title of *J. communis*, and very common in some parts of New England, deserves, perhaps, to be considered a distinct species. It is a trailing shrub, seldom more than two or three feet in height; spreading in all directions, throwing out roots from its branches, and forming beds which are often many rods in circumference. The name of *J. depressa* has been proposed for it. The common juniper flowers in May; but does not ripen its fruit till late in the following year. All parts of the plant contain a volatile oil, which imparts to them a peculiar flavour. The wood has a slight aromatic odour, and was formerly used for fumigation. A terebinthinate juice exudes from the tree and hardens on the bark. This has been erroneously considered as identical with *sandarach*, which is in fact the product of the *Thuya articulata*. The fruit and tops of juniper are the only officinal parts.

The berries, as the fruit is commonly called, are sometimes collected in this country, and parcels are occasionally brought to the Philadelphia market from New Jersey. But, though equal to the European in appearance, they are inferior in strength, and are not much used. The best come from the South of Europe, particularly from Trieste and the Italian ports. They are globular; more or less shrivelled; about as large as a pea; marked with three furrows at the summit, and with tubercles from the persistent calyx at the base; covered with a glaucous bloom, beneath which they are of a shining blackish-purple colour; and containing a brownish-yellow pulp and three angular seeds. They have an agreeable somewhat aromatic odour, and a sweetish, warm, bitterish, slightly terebinthinate taste. These properties, as well as their medical virtues, they owe chiefly to an essential oil which may be separated by distillation. (See *Oleum Juniperi*.) The other ingredients, according to Trommsdorff, are resin, sugar, gum, wax, lignin, water, and various saline substances. The proportion of these ingredients varies according to the greater or less maturity of the berries. The volatile oil is most abundant in those which have attained their full growth and are still green, or in those which are on the point of ripening. In the latter, Trommsdorff found one per cent. of the oil. In those which are perfectly ripe it has been partly changed into resin, and in those quite black, completely so. The berries impart their virtues to water and alcohol. They are very largely consumed in the preparation of gin.

The tops of juniper are directed by the London and Dublin Colleges. Their odour is balsamic, their taste resinous and bitterish; and they possess similar virtues with the berries.

Medical Properties and Uses. Juniper berries are gently stimulant and diuretic, imparting to the urine the smell of violets, and producing occasionally, when very largely taken, disagreeable irritation in the urinary passages. They are chiefly used as an adjuvant to more powerful diuretics in dropsical complaints; but have been recommended also in scorbutic and cutaneous diseases, catarrh of the bladder, and atonic conditions of the alimentary canal and uterus. They may be given in substance triturated with sugar, in the

dose of one or two drachms repeated three or four times a day. But the infusion is a more convenient form. It is prepared by macerating an ounce of the bruised berries in a pint of boiling water, the whole of which may be taken in the course of twenty-four hours. Extracts are prepared from the berries, both bruised and unbruised, and given in the dose of one or two drachms; but in consequence of the evaporation of the essential oil, they are probably not stronger than the berries in substance.

JUNIPERUS VIRGINIANA. *U.S. Secondary.*

Red Cedar.

“The tops of *Juniperus Virginiana*.” *U. S.*

JUNIPERUS. See JUNIPERUS.

Juniperus Virginiana. Willd. *Sp. Plant.* iv. 853; Bigelow, *Am. Med. Bot.* iii. 49; Michaux, *N. Am. Sylv.* iii. 221. This species of juniper, known commonly by the name of *red cedar*, is an evergreen tree of slow growth, seldom attaining a very large size, though sometimes rising forty or fifty feet in height, with a stem twelve or thirteen inches in diameter. It has numerous very close branches, which, in the young tree, spread out horizontally near the ground; but, as the tree advances, the lower branches slowly decay, leaving the trunk irregular with knots and crevices. The leaves are very small, fleshy, ovate, concave, pointed, glandular on their outer surface, either ternate or in pairs, and closely imbricated. Those of the young shoots are often much longer, and spreading. The leaves closely invest the extreme twigs, increasing with their growth, till ultimately lost in the encroachments of the bark. “The barren flowers are in oblong aments, formed by peltate scales with the anthers concealed within them. The fertile flowers have a proper perianth, which coalesces with the germ, and forms a small, roundish berry, with two or three seeds, covered on its outer surface with a bright blue powder.” (*Bigelow*.)

The red cedar grows in all latitudes of the United States, from that of Burlington in Vermont, to the Gulf of Mexico; but it is most abundant and of most vigorous growth in the southern section, and within a short distance of the ocean. The interior wood is of a reddish colour, and highly valuable on account of its great durability. Small excrescences which are sometimes found on the branches of the tree, are popularly used as an anthelmintic under the name of *cedar apples*. The tops or leaves only are officinal.

They have a peculiar not unpleasant odour, and a strong, bitterish, somewhat pungent taste. These properties reside chiefly in an essential oil, and are readily imparted to alcohol. The leaves, analyzed by Mr. Wm. J. Jenks were found to contain volatile oil, gum, tannic acid, albumen, bitter extractive, resin, chlorophylle, fixed oil, lime, and lignin. (*Am. Journ. of Pharm.* xiv. 235.) *

The leaves of the *J. Virginiana* bear a close resemblance to those of the *J. Sabina*, from which they can be certainly distinguished only by the difference of odour.

Medical Properties and Uses. The resemblance of red cedar to savine is said also to extend to their medical properties; the former being considered, like the latter, stimulant, emmenagogue, diuretic, and, under certain circumstances, diaphoretic. It is, however, much less energetic; and though

advantage may, as has been asserted, have accrued from its use in amenorrhœa, chronic rheumatism, and dropsy, it has not acquired the confidence of the profession generally. Externally applied it acts as an irritant; and an ointment prepared by boiling the fresh leaves for a short time in twice their weight of lard, with the addition of a little wax, is employed as a substitute for savine cerate in maintaining a purulent discharge from blistered surfaces. Sometimes the dried leaves in powder are mixed with six times their weight of resin cerate, and used for a similar purpose. But neither of these preparations is as effectual as the analogous preparations of savine. W.

KINO. *U.S., Lond., Ed., Dub.*

Kino.

“An extract obtained from an uncertain plant.” *U.S.* “*Pterocarpus erinaceus. Extractum.*” *Lond.* “Concrete exudation of *Pterocarpus erinaceus*, and of other undetermined genera and species.” *Ed.*

Kino, Fr., Germ., Ital.; Quino, Span.

The term kino was originally applied to a vegetable extract or inspissated juice taken to London from the western coast of Africa, and introduced to the notice of the profession by Dr. Fothergill. Vegetable products obtained from various other parts of the world, resembling kino in their appearance and properties, afterwards received the same name; and much confusion and uncertainty have existed, and to a considerable degree still exist, in relation to the botanical and commercial history of the drug. We shall first give an account of the general properties which at present entitle a medicine to the name of kino, and shall then treat of the several varieties.

General Properties. Kino, as found in the shops, is usually in small, irregular, angular, shining fragments, seldom so large as a pea, of a dark reddish-brown or blackish colour, very brittle, easily pulverizable, and affording a reddish powder, much lighter coloured than the drug in its aggregate state. If in larger masses, it may be reduced without difficulty into these minute fragments. It is without odour, and has a bitterish, highly astringent taste, with a somewhat sweetish after-taste. It burns with little flame, and does not soften with heat. It imparts its virtues and a deep-red colour to water and alcohol. Cold water forms with it a clear infusion. Boiling water dissolves it more largely; and the saturated decoction becomes turbid on cooling, and deposits a reddish sediment. The tincture is not disturbed by water. When long kept it often gelatinizes, and loses its astringency. (See *Tinctura Kino.*) Kino consists chiefly of a modification of tannic acid or tannin, with extractive, gum, and sometimes probably a little resin; but we need a careful analysis of the different well-ascertained varieties. The aqueous solution of kino is precipitated by gelatin, the soluble salts of iron, silver, lead, and antimony, the bichloride of mercury, and the sulphuric, nitric, and muriatic acids. The precipitate with iron is of an olive or greenish-black colour. The alkalies favour the solubility of kino in water, but essentially change its nature, and destroy its astringency.

1. *East India or Amboyna Kino.* This is the variety at present probably most used, and most highly esteemed. It is apparently an extract; but its origin is altogether unknown. It has been ascribed by some to the *Nauclea Gambir* of Mr. Hunter (*Uncaria Gambir* of Roxburgh); but the reference is altogether incorrect; as the product of this tree, now well known under the name of *gambir*, bears no resemblance to kino, and is generally ranked among the varieties of catechu. (See *Catechu*, page 194.)

The name of Amboyna kino would seem to imply that it comes in part at least from that island. But Pereira states that all the importations he could trace were from Bombay and Tellicherry; and he therefore conjectures that it is collected upon the Malabar coast. Roxburgh suggests that it may be derived from the *Pterocarpus Marsupium*, an East India tree, the juice of which is strongly and simply astringent, and hardens into a dark red very brittle mass, which assumes a lighter colour when powdered. (Lindley, *Flor. Med.* p. 256.) It is sometimes imported into this country directly from the East Indies, but more commonly from London. It comes from the East in boxes.

East India kino is in small, angular, glistening fragments, of a uniform consistence, appearing as if formed by the breaking down of larger masses. The larger fragments are opaque and nearly black; but minute splinters are sometimes translucent, and of a deep garnet redness when viewed by transmitted light. This variety of kino is very brittle, readily breaking between the fingers, and easily pulverized, affording a dark reddish powder, a portion of which, resulting from the mutual attrition of the fragments, is often found interspersed among them. When chewed, it softens in the mouth, adheres somewhat to the teeth, and tinges the saliva of a blood-red colour. In odour, taste, and chemical relations, it corresponds with the account already given of kino in general. It was analyzed by Vauquelin, and found to contain 75 per cent. of tannin and peculiar extractive, 24 of red gum, and 1 of insoluble matter. Pereira states that it has been shown by A. W. Buchner to contain *catechuin*, or *catechuic acid*. (See *Catechu*, p. 194.)

2. *West India or Jamaica Kino.* This is believed to be the product of the *Coccoloba uvifera*, or *sea-side grape*, a tree twenty feet or more in height, bearing beautiful broad shining leaves, and large bunches of purple berries, to which it owes its vernacular name. It grows in the West Indies and neighbouring parts of the continent. The kino is said to be obtained by evaporating a decoction of the wood and bark, which are very astringent. Many years since, a thick reddish-brown liquid was imported into Philadelphia from the West Indies, which, when dried by exposure to the air in shallow vessels or by heat, afforded an extract having all the properties of kino, for which it was sold by the druggists. This has been long exhausted; but, within a few years, a considerable quantity of West India kino has been brought into this market, and now enters into the consumption of the country. It is contained in large gourds, into which it has evidently been poured while in a liquid or semi-liquid state, and then allowed to harden.

When taken from the gourd, it breaks into fragments of various sizes, upon an average about as large as a hazel-nut, and having some tendency to the rectangular form. The consistence of these fragments is uniform, their surface smooth and shining, and their colour a dark reddish-brown, approaching to black. They are, however, not so glistening, nor so black as the East India kino. In mass they are quite opaque, but in thin splinters are translucent and of a ruby redness. They are readily broken by the fingers into smaller fragments, are easily pulverized, and yield a dull reddish powder, considerably lighter-coloured than that of the former variety. The West India kino is without odour, and has a very astringent bitterish taste, with a scarcely observable sweetish after-taste. It adheres to the teeth when chewed, though rather less than the East India variety, and colours the saliva red. The solubility of Jamaica kino was very carefully examined, at our request, by Dr. Robert Bridges of this city, who found that cold water dissolved 89 per cent., and ordinary official alcohol 94 per cent. The portion dissolved by alcohol and not by water was probably of a resin-

ous nature; as it appeared to be viscid, and very much impeded the filtration of the watery solution. Guibourt, who states that Jamaica kino is but slightly dissolved by cold water, must have operated on a different product. According to Bostock, it contains 41 per cent. of tannin.

3. *South American Kino.*—*Caracas Kino.* In 1839, when the last edition of this Dispensatory was published, an astringent extract had recently been introduced into our market, derived, as we were informed, from Caracas, and known by that name to the druggists. Since that period it has come much more into use, and now constitutes a considerable portion of the consumption of the country. It is probably the same as that described by Guibourt in the last edition of his *History of Drugs* as the kino of *Columbia*.

As imported, this variety of kino is in large masses, some weighing several pounds, covered with thin leaves, or exhibiting marks of leaves upon their unbroken surface, externally very dark, and internally of a deep reddish-brown or dark port-wine colour. It is opaque in the mass, but translucent in thin splinters, very brittle, and of a fracture always shining, but in some masses wholly rough and irregular, in others rough only in the interior, while the outer portion, for an inch or two in depth, breaks with a rather smooth and uniform surface like that of the West India kino. This outer portion is easily broken into fine angular fragments, while the interior crumbles quite irregularly. Some of the masses are very impure, containing pieces of bark, wood, leaves, &c.; others are more homogeneous, and almost free from impurities. The masses are broken up by means of a mill so as to resemble East India kino, from which, however, this variety differs in being more irregular, less sharply angular, more powdery, and less black. On comparing the finer and more angular portions of the masses with the West India kino, we were strongly struck with their resemblance; and in fact could discover no difference between the two varieties either in colour, lustre, taste, the colour of the powder, or other sensible property. South American kino was found by Dr. Bridges to yield 93·5 per cent. to cold water, and 93 per cent. to alcohol; so that, while it has almost the same solubility as Jamaica kino in alcohol, it is somewhat more soluble in cold water. The aqueous solution, in this case, was not embarrassed by the adhesive matter which impeded the filtration in the former variety; and the want of a minute proportion of resinous matter in the South American kino is the only difference we have discovered between the two drugs. It is not improbable that they are derived from the same plant; and there is no difficulty in supposing that this may be the *Coccoloba uvifera*, as that tree grows as well upon the continent as in the islands.

4. *African Kino.* The original kino employed by Dr. Fothergill was known to be the produce of a tree growing in Senegal, and upon the banks of the Gambia, on the western coast of Africa; but the precise character of the tree was not ascertained, until a specimen, sent home by Mungo Park during his last journey, enabled the English botanists to decide that it was the *Pterocarpus erinaceus* of Lamarek and Poiret. The London College accordingly refers kino to this plant; but in so doing has overlooked the fact, that not one of the varieties now used is brought from Africa. The importation of African kino has long ceased, and the most experienced pharmacologist cannot speak with certainty of having seen a specimen. That described by Guibourt has turned out to be the *Butea gum*;^{*} and the

* *Butea gum* is the concrete juice of the *Butea frondosa* or *Dhak-tree* of Hindostan. The juice flows from natural fissures, and from wounds made in the bark of the tree, and

description in Christison's Dispensatory evidently applies to the common East India kino. A specimen given to Dr. A. T. Thomson as African kino, and described in his Dispensatory, is certainly not the drug spoken of by Fothergill, but rather resembles the *Butea* gum.

As described by Fothergill, the African kino, for which he proposed the name of *gummi rubrum astringens Gambinense*, was in lumps of about the size of those of gum Senegal or dragon's blood, and so similar in appearance to the latter that a good judge might easily be deceived. These lumps were hard, brittle, opaque, and almost black; but minute fragments were reddish and transparent like garnet. The drug was inodorous, of a strongly astringent and sweetish taste, and soluble in water, to the extent of about five or six parts out of seven, forming a deep red astringent infusion. There can be little doubt that this variety of kino is a concrete juice, which exudes either spontaneously or from wounds in the bark, and hardens in the air. (See *Med. Obs. and Inq.* i. 358.)

5. *Botany Bay Kino*. This is the concrete juice of the *Eucalyptus resinifera*, or brown gum tree of New Holland, a lofty tree, belonging to the class and order *Icosandria Monogynia*, and the natural order *Myrtaceæ*. When the bark is wounded the juice flows very freely, and hardens in the air. According to Mr. White, a single tree is capable of furnishing five hundred pounds of kino in one year. (*White's Voyage*.) Duncan states that specimens of the juice have reached Great Britain in the fluid form, and that when he first examined kino in 1802, it was common, and was the finest kind in commerce. According to information received by Dr. Thomson, its importation into Great Britain must have ceased soon after that period (*Thomson's Dispensatory*, 1826, p. 506); but Dr. Pereira speaks of it as imported in boxes, and has himself met with a parcel of it from Van Diemen's Land. Ainslie informs us that he has met with it in the markets of Hindostan. Parcels may occasionally reach this country; but by such complicated routes that their origin is unknown.

The specimen examined by Pereira was in irregular masses, many of them in the form of tears as large as those of Senegal gum. "The purer pieces were vitreous, almost black in the mass, but transparent and of a beautiful ruby-red in small and thin fragments. Some of the pieces, however, were opaque and dull, from the intermixture of wood and other impurities." This variety of kino is brittle, with a resinous unequal fracture, and yields a reddish-brown powder. It is infusible, without odour, of an astringent taste followed by sweetness, and when long chewed adheres to the teeth. (*Duncan*.) It swells up and becomes gelatinous with cold water, yielding a red solution, which gives precipitates with lime-water, gelatin, and sesquichloride of iron, but not with alcohol or tartar-emetic. With

quickly hardens. It is in small elongated tears, or irregular angular masses, less in size than a grain of barley, apparently black and opaque, but translucent and of a ruby-red colour when examined in small fragments by transmitted light. Many of the tears have small portions of bark adhering to them. They are very brittle, and readily pulverizable, yielding a reddish powder. They are very astringent to the taste, do not adhere to the teeth when chewed, and tinge the saliva red. The relations of this product to water, alcohol and chemical reagents are nearly the same as those of ordinary kino. When freed from impurities, consisting of from 15 to 25 per cent. of wood, bark, sand, &c., it contains, according to Mr. E. Solly, 73.26 per cent. of tannin, 5.05 of soluble extractive, and 21.67 of gum and other soluble substances. It is used in the arts in India, and might undoubtedly be employed as kino in medicine. It is, however, very seldom imported into England, and never, at present, into this country. Dr. Pereira found a quantity in an old drug store in London, and sent a portion to Guibourt, from which that writer drew up his description of African kino. It is possible that the kino which formerly reached us, full of small pieces of wood, bark, &c., may have been the *Butea* gum.

rectified spirit it also becomes gelatinous, and forms a red tincture which is not precipitated by water. (*Pereira*.) White states that only one-sixth of this kino is soluble in water; Guibourt found it wholly soluble with the exception of foreign matters; and Dr. Thomson informs us that water at 60° dissolves more than one-half. These gentlemen must have experimented with different substances. According to Dr. Duncan, alcohol dissolves the whole except impurities; and the tincture, with a certain proportion of water, lets fall a copious red precipitate, but with a large proportion only becomes slightly turbid.

It is said that catechu, broken into small fragments, has sometimes been sold as kino. Fortunately little injury can result from the substitution, as the medical virtues of the two extracts are very nearly the same.

Medical Properties and Uses. Kino is powerfully astringent, and in this country is much used for the suppression of morbid discharges. In diarrhœa not attended with febrile excitement or inflammation, it is often an excellent adjunct to opium and the absorbent medicines, and is a favourite addition to the chalk mixture. It is also used in chronic dysentery when astringents are admissible; in leucorrhœa and diabetes; and in passive hemorrhages, particularly that from the uterus. It was formerly used in intermittent fever, but has given way to more efficient remedies.

It may be given in powder, infusion, or dissolved in diluted alcohol. The dose of the powder is from ten to thirty grains. The infusion, which is a very convenient form of administration, may be made by pouring eight fluidounces of boiling water on two drachms of the extract, and straining when cool. Aromatics may be added if deemed advisable. The dose is a fluidounce. The proportion of alcohol in a dose of the tincture, renders it frequently an unsuitable preparation.

Locally applied, kino is often productive of benefit. Its infusion is useful as an injection in leucorrhœa and obstinate gonorrhœa, and thrown up the nostrils we have found it very efficacious in suppressing hemorrhage from the Schneiderian membrane. A case of obstinate hemorrhage from a wound in the palate, after resisting various means, yielded to the application of powdered kino, which was spread thickly on lint, and pressed against the wound by the tongue. The powder is also a very useful application to indolent and flabby ulcers.

Krameria triandra. Ruiz and Pavon, *Flor. Peruv.* i. 61. The rhatany

plant is a shrub having a long, much branched, and spreading root, of a blackish-red colour; with a round, procumbent, very dark-coloured stem, divided into numerous branches, of which the younger are leafy and thickly covered with soft hairs, giving them a white, silky appearance. The leaves are few, sessile, oblong-ovate, pointed, entire, presenting on both surfaces the same silky whiteness with the young branches, on the sides of which they are placed. The flowers are lake-coloured, and stand singly on short peduncles at the axils of the upper leaves. There are only three stamens. The nectary consists of four leaflets, of which the two upper are spatulate, the lower roundish and much shorter: it does not correspond with the generic character of Willdenow, which was drawn from the *Krameria Ixina*. The fruit is globular, of the size of a pea, surrounded by stiff reddish-brown prickles, and furnished with one or two seeds.

This species of *Krameria* is a native of Peru, growing in dry argillaceous and sandy places, and abundant about the city of Huanuco. It flowers at all seasons, but is in the height of its bloom in October and November. The root is dug up after the rains.

The *K. Ixina*, growing in Hayti, and in Cumana on the South American continent, is said to afford a root closely analogous in appearance and properties to that of the Peruvian species; but the latter only is officinal.

The name *rhatany* is said to express, in the language of the Peruvian Indians, the creeping character of the plant.

We receive *rhatany* in pieces of various shapes and dimensions, some being simple, some more or less branched, the largest as much as an inch in thickness, being derived from the main body of the root, the smallest not thicker than a small quill, consisting of the minute ramifications. The pieces are often nearly cylindrical, and as much as two or three feet in length. Sometimes many of the radicles are united in a common head, which is short, and from half an inch to two inches or more in diameter. The roots are composed of a dark reddish-brown, slightly fibrous, easily separable bark, and a central woody portion, less coloured, but still reddish, or reddish-yellow. The root is without smell, but has a bitter, very astringent, slightly sweetish taste, which is connected with its medical virtues, and is much stronger in the cortical than the ligneous part. The smallest pieces are therefore preferable, as they contain the largest proportion of the bark. The powder is of a reddish colour. The virtues of the root are extracted by water and alcohol, to which it imparts a deep reddish-brown colour. From the researches of Vogel, Gmelin, Peschier, and Trommsdorff, it appears to contain tannin, lignin, and minute quantities of gum, starch, saccharine matter, and an acid which Peschier considered as peculiar, and named *krameric acid*. The tannin is in three states; 1st, in that of purity, in which it is without colour; 2d, that of apotheme, in which it has lost its astringency and been rendered insoluble by the action of the air, and 3d, that of extractive, which is a soluble combination of tannin and its apotheme, and is the substance which imparts their characteristic reddish-brown colour to the infusion and tincture of *rhatany*. (Soubeiran, *Journ. de Pharm.* xix. 596.) The proportion of red astringent matter obtained by Vogel was 40 per cent. The mineral acids and most of the metallic salts throw down precipitates with the infusion, decoction, and tincture of *rhatany*, and are incompatible in prescription.

Cold water, by means of displacement or percolation, extracts all the astringency of *rhatany*, forming a clear deep-red infusion, which, upon careful evaporation, yields an almost perfectly soluble extract. The root yields its virtues also to boiling water by maceration; but the resulting infu-

sion becomes turbid upon cooling, in consequence of the deposition of apotheme taken up by the water when heated. By boiling with water a still larger proportion of the apotheme is dissolved, and a considerable quantity of the pure tannin becomes insoluble in cold water, and medicinally inert, either by combining with the starch which is also dissolved, or by conversion into apotheme through the agency of the atmosphere. The decoction is, therefore, an ineligible preparation, and the extract resulting from its evaporation, though greater in absolute weight than that from the cold infusion, contains much less soluble and active matter. Alcohol dissolves a larger proportion of the root than water, but this excess is owing to the solution of apotheme; and the alcoholic extract contains little if any more of the astringent principle than that prepared by cold water, while it is encumbered with much inert matter. (See *Extractum Kramerizæ*.)

Medical Properties and Uses. Rhatany is gently tonic and powerfully astringent; and may be advantageously given in chronic diarrhœa, passive hemorrhages, especially menorrhagia, some forms of leucorrhœa, and in all those cases in which kino and catechu are beneficial. It has long been used in Peru as a remedy in bowel complaints, as a corroborant in cases of enfeebled stomach, and as a local application to spongy gums. Ruiz, one of the authors of the Peruvian Flora, first made it known in Europe. It was not till after the year 1816 that it began to come into general use. In this country it is now extensively employed. It has the advantage over the astringent extracts imported, that, being brought in the state of the root, it is free from adulteration, and may be prescribed with confidence.

The dose of the powder is from twenty to thirty grains; but in this form the root is little used. The infusion or decoction is more convenient, and is usually preferred. The proportions are an ounce of the bruised or powdered root to a pint of water, and the dose one or two fluidounces. The extract, tincture, and syrup are officinal preparations; and may be given, the first in the dose of fifteen or twenty grains, the second in that of two or three fluidrachms, and the third in that of half a fluidounce for an adult. In the form of infusion, tincture, and extract, rhatany has been highly recommended as a local remedy in fissure of the anus, prolapsus ani, and leucorrhœa. (See a paper by Drs. Johnston and Biddle, in the *Medical Examiner*, iv. 293.)

Off. Syn. LITMUS. *Roccella tinctoria.* Dub.

Turnsol, Orchill; Tournesol, Fr.; Lakmus, Germ.; Oricello, Ital.; Orchilla, Span.

Various species of lichens afford, when macerated with alkaline liquors, a purple colouring matter much esteemed in dyeing. That most used at present is the *cudbear*, prepared from the *Lichen tartareus*, which grows on limestone rocks in the North of Europe. The *orchill* or *litmus* is a similar dye-stuff, prepared from the *Roccella tinctoria* of Acharius, a lichen which grows on maritime rocks, and is especially abundant in the Canary and Cape Verd Islands.

Litmus is prepared by coarsely powdering the lichen, and macerating and fermenting it in close wooden vessels, for several weeks, with urine and either potash or soda. The colouring matter is thus evolved, and the prepared mass is taken out, dried, and cut into small squares for use.

Litmus, as thus prepared, is in friable, violet-coloured, finely granular pieces, from a quarter of an inch to an inch in diameter, scattered over with white saline points. It has an alkaline smell, tinges the saliva of a deep blue, and is somewhat pungent and saline to the taste. It is much used as one of the most delicate tests of uncombined acids, which change its blue colour to red; and of alkalies, which restore the original hue. The most convenient mode of preparing litmus for use as a test, is to stain paper with it. For this purpose the watery infusion made with one part of powdered litmus and four of water, is applied by means of a brush to white unsized paper. The sheets when dried must be kept in close vessels in the dark.

LACTUCA ELONGATA. U.S. Secondary.

Wild Lettuce.

"The herb of *Lactuca elongata*." U. S.

LACTUCA. *Sex. Syst.* Syngenesia *Æqualis*.—*Nat. Ord.* Compositæ-Cichoraceæ, *De Cand.* Cichoraceæ, *Lindley*.

Gen. Ch. Receptacle naked. *Calyx* imbricated, cylindrical, with a membranous margin. *Pappus* simple, stipitate. *Seed* smooth. *Willd.*

Lactuca elongata. Willd. *Sp. Plant.* iii. 1525. This indigenous species of lettuce is biennial, with a stem from three to six feet in height, and leaves of which the lower are runcinate, entire, and clasping, the lowest toothed, and the highest lanceolate. They are all smooth on their under surface. The flowers are in corymbose panicles, small, and of a pale yellow colour. The stem and leaves yield, when wounded, a milky juice in which the virtues of the plant reside.

The *wild lettuce* grows in all latitudes of the United States, from Canada to the Carolinas. It is found in woods, along roads, and in fertile soils, and flowers in June and July.

It was introduced into the secondary list of the U. S. Pharmacopœia as a substitute for the *Lactuca virosa* of Europe, which it is said to resemble somewhat in medical properties. Dr. Bigelow was informed by physicians who had employed it, that it acts as an anodyne, and promotes the secretion from the skin and kidneys. It is seldom used in regular practice.

An extract prepared by expressing and inspissating the juice of the fresh plant may be given in doses of from five to fifteen grains. (*Bigelow's Sequel.*)

LACTUCA VIROSA. Folia. Dub.

Strong-scented Lettuce.

Laitue vireuse, *Fr.*; Gift-Lattig, *Germ.*; Lattoga salvatica, *Ital.*

LACTUCA. See LACTUCA ELONGATA.

Lactuca virosa. Willd. *Sp. Plant.* iii. 1526; Woodv. *Med. Bot.* p. 75. t. 31. The strong-scented lettuce is biennial, with a stem from two to four feet high, erect, prickly near the base, above smooth and divided into branches. The lower leaves are large, oblong obovate, undivided, toothed,

commonly prickly on the under side of the midrib, sessile, and horizontal; the upper are smaller, clasping, and often lobed; the bractes are cordate and pointed. The flowers are numerous, of a sulphur-yellow colour, and disposed in a panicle. The plant is lactescent, and has a strong disagreeable smell like that of opium, and a bitterish acrid taste. The inspissated expressed juice is the part usually employed in medicine. It should be prepared while the plant is in flower; as the milky fluid, upon which its virtues depend, is then most abundant. Mr. Duncan, of Edinburgh, has prepared lactucarium from this species, which is said to yield it in greater quantity, and of better quality than the garden lettuce. Mr. Schutz, of Germany, obtained only 17 grains of lactucarium, on the average, from a single plant of the garden lettuce, while a plant of the *L. virosa* yielded 56 grains. The strong-scented lettuce is a native of Europe.

Medical Properties and Uses. The extract or inspissated juice is a sedative narcotic, said also to be gently laxative, powerfully diuretic, and somewhat diaphoretic. It is employed in Europe, particularly in Germany, in the treatment of dropsy, and is especially recommended in cases attended with visceral obstruction. Dr. Collin of Vienna was very successful with it in the cure of that disease. It is usually, however, combined with squill, digitalis, or some other diuretic; and it is not easy to decide how much of the effect obtained is justly ascribable to the lettuce. The medicine is never used in this country. The dose is eight or ten grains, which may be gradually increased to a scruple or more. The *Lactuca Scariola*, another European species, possesses similar properties, and is used for the same purposes. W.

LACTUCA. See LACTUCA ELONGATA.

Lactuca sativa. Willd. *Sp. Plant.* ii. 1523. The garden lettuce is an annual plant. The stem, which rises above two feet in height, is erect round, simple below, and branching in its upper part. The lower leaves are obovate, rounded at the end, and undulating; the upper are smaller, sessile, cordate, and toothed; both are shining, and of a yellowish-green colour. The flowers are pale yellow, small, and disposed in an irregular terminal corymb. Before the flower-stem begins to shoot, the plant contains a bland, pellucid juice, has little taste or smell, and is much used as a salad for the table; but during the period of inflorescence it abounds in a peculiar milky juice, which readily escapes from incisions in the stem, and has been found to possess decided medicinal as well as sensible properties. A similar juice is produced by all the other species of lettuce, and has in fact served as the

origin of the title by which the genus is designated. This juice is more abundant in the wild than in the cultivated plants. That of the *L. sativa*, inspissated by exposure to the air, has been adopted as official in the U.S., London, and Edinburgh Pharmacopœias, under the name of *Lactucarium*. The Edinburgh College admits also the *L. virosa* as one of the sources of this medicine. In the edition of the London Pharmacopœia of 1836, lettuce has been omitted from the *Materia Medica*; but we have retained it here; as an extract of lettuce is directed in the same edition, among the Preparations.

The original native country of the garden lettuce is unknown. The plant has been cultivated from time immemorial, and is now employed in all parts of the civilized world. It flourishes equally well in hot and temperate latitudes. Some botanists suppose that the *L. virosa* of the old continent is the parent of all the varieties of the cultivated plant.

The milky juice undergoes little alteration, if confined in closely stopped bottles from which the air is excluded. But when exposed to the air, it concretes and assumes a brownish colour somewhat like that of opium. Mr. Young, of Edinburgh, recommended the following mode of collecting it. When the stem is about a foot high, the top is cut off, and the juice which exudes, being absorbed by cotton or a piece of sponge, is pressed out into a cup or other small vessel, and exposed till it concretes. In order to obtain all the juice which the plant is capable of affording, it is necessary to cut off five or six successive slices of the stem at short intervals, and to repeat the process two or three times a day. The juice may also be collected by the finger as it flows from the incisions.

A plan proposed by Mr. Probart of London, is to collect the milky juice on pieces of woven cotton about half a yard square, to throw these when fully charged into a vessel containing a small quantity of water, and allow the water thus impregnated to evaporate in shallow dishes at the ordinary temperature of the atmosphere. The lactucarium is left in the form of an extract, differing from the concrete juice chiefly in being destitute of caoutchouc.

Another method of extracting the virtues of the lettuce has been recommended by Mr. Probart. When the plant begins to assume a yellow hue, the white juice concretes in the bark of the stem, and in the old leaves, which become very bitter. These parts being separated, are macerated for twenty-four hours in water, then boiled for two hours; and the clear decoction, after having been allowed to drain off through a sieve without pressure, is evaporated in shallow vessels by simple exposure. The resulting extract, according to Mr. Probart, has half the strength of lactucarium, and may be obtained at one-sixth of the cost.

The London College directs an extract to be prepared by inspissating the expressed juice of the leaves; but this must be exceedingly uncertain, from the variable quantity of the milky juice contained in the plant; and as the young leaves, which contain little or none of it, are often employed, the preparation is liable to be quite inert. The proper lactucarium is greatly preferable.

It has been asserted that the *thridace* of Dr. François is the inspissated milky juice of lettuce, and therefore identical with lactucarium; and a statement to this effect was made in some former editions of this work, upon what was deemed sufficient authority. In an article, however, in the *Journal de Pharmacie* for December 1836, it is asserted that *thridace* strongly attracts moisture from the air, is without narcotic odour, and instead of being bitter, like lactucarium, has a saline and extractive taste. It is, therefore,

in all probability, the inspissated expressed juice, and, indeed, is directed as such in the last French Codex, the leaves being rejected, and the stalks alone, near the flowering period, being subjected to pressure.

Lactucarium is in small irregular lumps, of a reddish-brown colour externally, and of a narcotic odour and bitter taste. As prepared near Edinburgh it is commonly in roundish, compact, and rather hard masses, weighing several ounces. (*Christison*.) In colour, taste, and smell, it bears considerable resemblance to opium, and has sometimes been called *lettuce opium*. It does not attract moisture from the air. It yields nearly half its weight to water, with which it forms a deep-brown infusion. From experiments made by Dr. Klink, assisted by Professor Pfaff of Kiel, the undissolved portion appears to consist of wax, resin, and caoutchouc. From its resemblance in sensible properties and therapeutical effects to opium, it was conjectured to contain morphia, or some analogous principle; but none such has been discovered. Analyzed by M. Aubergier, an apothecary of Clermont, it yielded 1. a bitter crystallizable principle, soluble in alcohol and boiling water, slightly soluble in cold water, insoluble in ether, without alkaline reaction, and supposed to be the active principle; 2. mannite; 3. asparamide; 4. a free acid; 5. a brown colouring substance; 6. resin, cerin, myricin, albumen, and gum; 7. nitrate of potassa, chloride of potassium, and phosphates of lime and magnesia. (*Journ. de Pharm. N. S. i. 78.*) Dr. Walz, in an inaugural thesis published at Heidelberg in 1839, gives the following constituents of lactucarium from the *L. virosa*;—viz., a peculiar principle denominated *lactucin*, volatile oil, a fatty matter easily dissolved by ether, and another of difficult solubility in that fluid, a reddish-yellow tasteless resin, a greenish-yellow acrid resin, common sugar, uncrystallizable sugar, gum, pectic acid, a brown humus-like acid, a brown basic substance, albumen, oxalic, citric, malic, and nitric acids, potassa, lime, and magnesia. *Lactucin* is obtained by exhausting lactucarium with alcohol acidulated with a fiftieth of acetic acid, diluting the tincture with an equal bulk of water, adding acetate of lead so long as a precipitate is produced, washing the precipitate with weak alcohol acidulated with vinegar, filtering the liquors, freeing them from lead by hydrosulphuric acid, evaporating to dryness at a heat of from 135° to 145° F., exhausting the extract thus obtained with absolute alcohol, evaporating to dryness, treating the residue again with ether, and allowing the ether to evaporate spontaneously. *Lactucin* is thus obtained in yellow crystalline needles, without smell, of a strong and durable bitter taste, easily fusible, soluble in from 60 to 80 parts of cold water, freely soluble in alcohol, less so in ether, soluble in very dilute acids, and possessing neither alkaline nor acid reaction. The substance called by Buchner *lactucin*, contains besides the proper *lactucin* numerous other principles. (*Annal. der Pharm. xxxii. 97.*)

Medical Properties and Uses. That lettuce possesses soporific properties, is a fact which was known to the ancients; but Professor Coxe, of Philadelphia, enjoys the credit of having first proposed the employment of its inspissated milky juice as a medicine. From experiments with a tincture prepared from lactucarium, Dr. Coxe obtained the same results as usually follow the administration of common laudanum. Dr. Duncan, senior, of Edinburgh, afterwards paid particular attention to the subject, and, in his treatise on pulmonary consumption, recommended lactucarium as a substitute for opium, the anodyne properties of which it possesses, without being followed by the same injurious effects. In consequence of this recommendation the medicine came into extensive use, and was adopted as officinal in several of the Pharmacopœias. Dr. François, a French phy-

sician, also investigated, with great care, the medicinal properties of the inspissated juice of lettuce. According to this author, it is sedative in its action, diminishing the rapidity of the circulation, and consequently the temperature of the body, without producing that disturbance of the functions which often follows the use of opium. In this country the medicine is habitually employed by some practitioners to allay cough, and quiet nervous irritation. It may be given in all cases in which opium is indicated in reference to its anodyne or soothing influence, but cannot be administered from idiosyncrasy of the patient. It is, however, a very uncertain medicine.

The dose of lactucarium has usually been stated at two grains to be repeated if necessary, but this is too small. From five to twenty grains may be given.

Water distilled from lettuce (*eau de laitue*) is used in France as a mild sedative, in the quantity of from two to four ounces. The fresh leaves boiled in water are sometimes employed in the shape of cataplasms. It is said that in Egypt a mild oil is derived from the seeds, fit for culinary use. (*Fée.*)

LAURUS. *Sex. Syst.* Enneandria Monogynia.—*Nat. Ord.* Lauracæ.

Gen. Ch. Flowers diœcious or hermaphrodite, involucreted. *Calyx* four-parted; segments equal, deciduous. *Fertile stamens* twelve in three rows; the outer alternate with the segments of the calyx; all with two glands in the middle or above it. *Anthers* oblong, two-celled, all looking inwards. *Fertile flowers* with two to four castrated males surrounding the ovary. *Stigma* capitate. *Fruit* succulent, seated in the irregular base of the calyx. Umbels axillary, stalked. (*Lindley, Flor. Med.* 340.)

Laurus nobilis. Willd. *Sp. Plant.* ii. 479; Woodv. *Med. Bot.* p. 678. t. 235. This species of laurel is an evergreen tree, attaining in its native climate the height of twenty or thirty feet. Its leaves are alternate, on short petioles, oval lanceolate, entire, sometimes wavy, veined, of a firm texture, smooth, shining, deep green upon their upper surface, paler beneath. The flowers are diœcious, of a yellowish-white colour, and placed in small clusters of three or four together upon a common peduncle in the axils of the leaves. The corolla is divided into four oval segments. The fruit is an oval berry, of the size of a small cherry, and when ripe of a dark purple, nearly black colour.

The bay tree, so famous among the ancients, is a native of the countries bordering on the Mediterranean. Its leaves and fruit, and an oil expressed from the latter, are the officinal parts.

The leaves have a fragrant odour, especially when bruised, and a bitter, aromatic, somewhat astringent taste. They yield by distillation a greenish-yellow volatile oil, upon which their properties chiefly depend. Water distilled from them has their peculiar odour.

The berries when dried are black and wrinkled, and contain two oval,

fatty seeds within a thin, friable envelope; or they may be considered as drupes, with a kernel divisible into two lobes. They have the same aromatic odour and taste as the leaves, but are more pungent. Besides an essential oil, they contain also a fixed oil, which may be separated by expression or decoction.

The expressed oil, which is obtained from the fresh fruit, is concrete, of a greenish colour, and retains a portion of the volatile oil, which renders it agreeably aromatic. Lard impregnated with the odorous principle of the berries, and coloured green, is said to be often substituted for the genuine expressed oil.

Medical Properties and Uses. The leaves, berries, and oil of the bay tree possess excitant and narcotic properties, but at present are never used internally as medicines, and in this country are scarcely employed in any manner. Their chief use is to communicate a pleasant odour to external stimulant remedies. Dr. A. T. Thomson says that he has found an infusion of the berries useful in impetigo.

CERASUS. *Sex. Syst.* Icosandria Monogynia.—*Nat. Ord.* Amygdaleæ.

Gen. Ch. Differing from *Prunus* only in its fruit being destitute of bloom, with the stone round instead of acute, and the leaves when in bud folded flat, not rolled up. (*Lindley, Flor. Med.* 232.)

Cerasus Lauro-cerasus. *De Cand. Prodr.* ii. 540.—*Prunus Lauro-cerasus.* *Willd. Sp. Plant.* ii. 988; *Woodv. Med. Bot.* p. 513. t. 185.—This is a small evergreen tree, rising fifteen or twenty feet in height, with long spreading branches, which, as well as the trunk, are covered with a smooth blackish bark. The leaves, which stand alternately on short strong footstalks, are oval oblong, from five to seven inches in length, acute, finely toothed, firm, coriaceous, smooth, beautifully green and shining, with oblique nerves, and yellowish glands at the base. The flowers are small, white, strongly odorous, and disposed in simple axillary racemes. The fruit consists of oval drupes, very similar to small black cherries, both in their shape and internal structure.

The cherry-laurel is a native of Asia Minor, but has been introduced into Europe, throughout which it is cultivated, both for medical use and for the beauty of its shining evergreen foliage. Almost all parts of it are more or less impregnated with the odour supposed to indicate the presence of hydrocyanic acid. The leaves only are official.

In their recent and entire state they have scarcely any smell, but when bruised they emit the characteristic odour of the plant in a high degree. Their taste is somewhat astringent and strongly bitter, with the peculiar flavour of the peach kernel. By drying they lose their odour, but retain their bitterness. They yield a peculiar volatile oil and hydrocyanic acid by distillation with water, which they strongly impregnate with their flavour. The oil resembles that of bitter almonds, for which it is said to be sometimes sold in the shops in Europe, where it is employed to flavour liquors and various culinary preparations; but, as it is highly poisonous,

dangerous consequences may result from its careless use. It has not yet been determined how far the mode of production of this oil resembles that of bitter almonds (see *Amygdala Amara*); but chemists have not succeeded in obtaining amygdalin from the leaves; and that the oil exists already formed, to a certain extent, in the fresh leaves, is rendered probable by the fact, stated by Winkler, that they yield it in considerable quantity when distilled without water. (*Journ. de Pharm.* xxv. 195.) The fresh leaves are occasionally used to flavour milk, cream, &c.; and more safely than the oil; though they also are poisonous when too largely employed.

Medical Properties and Uses. The leaves of the cherry-laurel possess properties similar to those of hydrocyanic acid; and the water distilled from them is much employed in various parts of Europe for the same purposes as that active medicine. But it is deteriorated by age; and therefore, as kept in the shops, must be of variable strength. Hence, while Hufeland directs only twenty drops for a dose every two hours, to be gradually increased to sixty drops, M. Fouquier has administered several ounces without effect. Another source of inequality of strength must be the variable quality of the leaves, according to the time they have been kept after separation from the tree, and probably also to their age and degree of development. It is not, therefore, to be regretted, that the want of the plant in this country has prevented the introduction of the distilled water into our shops. W.

LAVANDULA. *Sex. Syst.* Didynamia Gymnospermia.—*Nat. Ord.* Lamiales or Labiales.

Gen. Ch. Calyx ovate, somewhat toothed, supported by a bracte. Corolla resupine. Stamens within the tube. *Willd.*

Lavandula vera. De Cand. *Flor. Fr. Sup.* p. 398.—*L. Spica.* Willd. *Sp. Plant.* iii. 60; Woodv. *Med. Bot.* p. 321. t. 114.—The *Lavandula Spica* of Linnæus includes two distinct species, which were considered by him merely as varieties of the same plant, but have been separated by subsequent botanists. Of these, the officinal plant, the narrow-leaved variety of Linnæus, has been denominated by De Candolle *L. vera*, while the broad-leaved variety still retains the title of *L. Spica*. The latter is scarcely cultivated in Great Britain or the United States.

The common lavender is a small shrub, usually rising not more than two or three feet, but sometimes attaining an elevation of six feet. The stem is woody below, and covered with a brown bark; above, is divided into numerous slender, straight, herbaceous, pubescent, quadrangular branches, furnished with opposite, sessile, narrow, nearly linear, entire, and green or glaucous leaves. The flowers are small, blue, and disposed in interrupted whorls around the young shoots, forming terminal cylindrical spikes. Each whorl is accompanied with two bractes. The corolla is tubular and labiate, with the lower lip divided into three segments, the upper larger and bifid. The filaments are within the tube.

The plant is a native of Southern Europe, and covers vast tracts of dry and barren land in Spain, Italy, and the South of France. It is cultivated

abundantly in our gardens, and in this country flowers in August. All parts of it are endowed with properties similar to those for which the flowers are used; but these only are officinal. The spikes should be cut when they begin to bloom.

Lavender flowers have a strong fragrant odour, and an aromatic, warm, bitterish taste. They retain their fragrance a long time after drying. Alcohol extracts their virtues; and a volatile oil upon which their odour depends rises with that liquid in distillation. The oil may be procured separate by distilling the flowers with water. (See *Oleum Lavandulæ*.) Hagen obtained from a pound of the fresh flowers sometimes two drachms, sometimes only half a drachm of the oil.

Medical Properties and Uses. Lavender is an aromatic stimulant and tonic, esteemed useful in certain conditions of nervous debility, but very seldom given in its crude state. The products obtained by its distillation are much used in perfumery, and as grateful additions to other medicines, which they render at the same time more acceptable to the palate and cordial to the stomach.

Lemons, Citrons, Fr.; Limonen, Citronen, Germ.; Limoni, Ital.; Limones, Span.

For some general remarks on the genus CITRUS, see the article *Aurantii Cortex*.

Citrus medica. Willd. *Sp. Plant.* iii. 1426; Woodv. *Med. Bot.* p. 582. t. 189. This tree closely resembles in its general aspect the *C. Aurantium* before described. The leaves, however, are larger, slightly indented at the edges, and stand upon footstalks which are destitute of the winged appendages that characterize the other species. The flowers, moreover, have a purplish tinge on their outer surface, and the fruit is entirely different in appearance from the orange. There are several varieties of the *Citrus medica*, which some botanists consider entitled to the rank of species, but which are scarcely distinguishable, except by the character of their fruit. Those which are particularly deserving of notice are the citron, lemon, and lime. 1. In the citron, *C. medica* of Risso, the fruit is very large, sometimes six inches in length, ovoidal with a double rind, of which the outer layer is yellowish, thin, unequal, rugged, with innumerable vesicles filled with essential oil; the inner is white, very thick, and spongy. It is divided

in the interior into nine or ten cells, filled with oblong vesicles, which contain an acid juice precisely like that of the lemon, and used for the same purposes. The rind is applied to the preparation of conserves, to which it is adapted by its great thickness. This fruit is called *cedrat* by the French. 2. The lemon—*C. medica*, variety *limon* of Linnæus—the *Citrus Limonium* of Risso—is smaller than the preceding variety, with a smoother and thinner rind, a pointed nipple-shaped summit, and a very juicy and acid pulp. In other respects it bears a close resemblance to the citron, to which, however, it is usually preferred in consequence of the greater abundance of its juice. 3. The lime is still smaller than the lemon, with a smoother and thinner rind, of an oval shape, rounded at the extremities, of a pale-yellow or greenish-yellow colour, and abounding in a very acid juice, which renders it highly useful for all the purposes to which the lemon is applied. It is the product of the variety *C. acris* of Miller.

The *Citrus medica*, like the orange-tree, is a native of Asia. It was introduced into Europe from Persia or Media, was first cultivated in Greece, afterwards in Italy, so early as the second century, and has now spread over the whole civilized world, being raised by artificial heat, where the climate is too cold to admit of its exposure with safety during winter to the open air.

We are supplied with lemons and limes chiefly from the West Indies and the Mediterranean. Though the former of these fruits only is directed by the United States Pharmacopœia, both kinds are employed indiscriminately for most medicinal purposes; and the lime affords a juice at least equal in proportional quantity, and in acidity, to that obtained from the lemon.

Properties. The exterior rind of the lemon has a fragrant odour, and a warm, aromatic, bitter taste, somewhat similar to that of the orange, though less agreeable. It contains a bitter principle, and yields, by expression or distillation, an essential oil which is much used for its flavour. Both this and the rind itself are recognised as officinal in all the Pharmacopœias. (See *Oleum Limonis*.) Lemon-peel yields its virtues to water, wine, and alcohol.

But the juice is the part for which this fruit is most esteemed. It is very sharply acid, with a peculiar grateful flavour, and consists chiefly of citric acid, mucilage, and extractive, dissolved in water. As lemons cannot always be obtained, the juice is often kept in a separate state; but from its liability to spontaneous decomposition, it speedily becomes unfit for medical use; and, though various means have been resorted to for its preservation, it can never be made to retain for any length of time its original flavour unaltered. The best medicinal substitute for lemon-juice, when the fresh fruit is not attainable, is a solution of crystallized citric acid in water, in the proportion of about an ounce to the pint, with the addition of a little oil of lemons.* One of the most effectual methods of preserving the juice is to allow it to stand for a short time after expression till a coagulable matter separates, then to filter, and introduce it into glass bottles, with a stratum of almond oil or other sweet oil upon its surface. It may also be preserved by concentrating it either by means of evaporation with a gentle heat, or by exposure to a freezing temperature, which congeals the watery portion, and leaves the acid much stronger than before. When wanted for use it may be diluted to the former strength; but though the acid properties are retained, the flavour of the juice is found to have been deteriorated.

Medical Properties and Uses. The rind of the lemon is sometimes used

* Nine drachms and a half dissolved in a pint of water, forms a solution of the average strength of lime-juice; but where precision is not requisite, the proportion mentioned in the text is most convenient.

to qualify the taste and increase the power of stomachic infusions and tinctures. The juice is refrigerant, and properly diluted forms a refreshing and very agreeable beverage in febrile and inflammatory affections. It may be given with sweetened water in the shape of lemonade, or may be added to the mildly nutritive drinks, such as gum-water, barley-water, &c., which are usually administered in fevers. It is also much employed in the formation of those diaphoretic preparations known generally by the names of *neutral mixture*, and *effervescing draught*. (See *Liquor Potassæ Citratis*, in the second part of this work.) One of the most beneficial applications of lemon-juice is to the prevention and cure of scurvy, for which it may be considered almost a specific. For this purpose, ships destined for long voyages should always be provided with a supply of the concentrated juice, or of crystallized citric acid with the oil of lemons. Lemon-juice is sometimes prescribed in connexion with opium and Peruvian bark, the effects of which it is thought in some instances to modify favourably, by substituting the citrate of their respective alkalies for the native salts. It has been used with advantage as a local application in pruritus of the scrotum, and in uterine hemorrhage after delivery.

LINUM. *Sex. Syst.* Pentandria Pentagynia.—*Nat. Ord.* Linaceæ.

Gen. Ch. Calyx five-leaved. Petals five. Capsule five-valved, ten-celled. Seeds solitary. *Willd.*

Linum usitatissimum. *Willd. Sp. Plant.* i. 1533; *Woodv. Med. Bot.* p. 565. t. 202. Common flax is an annual plant with an erect, slender, round stem, about two feet in height, branching at top, and, like all other parts of the plant, entirely smooth. The leaves are small, lanceolate, acute, entire, of a pale-green colour, sessile, and scattered alternately over the stem and branches. The flowers are terminal and of a delicate blue colour. The calyx is persistent, and composed of five ovate, sharp-pointed, three-nerved leaflets, which are membranous on their border. The petals are five, obovate, striated, minutely scalloped at their extremities, and spread into funnel-shaped blossoms. The filaments are also five, united at the base; and the germ, which is ovate, supports five slender styles, terminating in obtuse stigmas. The fruit is a globular capsule, about the size of a small pea, having the persistent calyx at the base, crowned with a sharp spine, and containing ten seeds in distinct cells.

This highly valuable plant, now almost everywhere cultivated, is said by some to have been originally derived from Egypt, by others from the great elevated plain of central Asia. It flowers in June and July, and ripens its

seeds in August. Both the seeds, and an oil expressed from them, are officinal.

The seeds are oval, oblong, flattened on the sides with acute edges, somewhat pointed at one end, about a line in length, smooth, glossy, of a brown colour externally, and yellowish-white within. They are without smell, and have an oily mucilaginous taste. Meyer found them to contain fixed oil, wax, resin, extractive, tannin, gum, azotized mucilage, starch, albumen, gluten, and various salts. Their investing coat or husk abounds in a peculiar gummy matter or mucilage, which is readily imparted to hot water, forming a thick viscid fluid, which lets fall white flakes upon the addition of alcohol, and affords a copious dense precipitate with subacetate of lead. By Berzelius the term *mucilage* is applied to a proximate vegetable principle, distinguished from gum by being insoluble in cold, and but slightly soluble in boiling water, in which it swells up and forms a mucilaginous, viscid body, which loses its water when placed upon filtering paper, or other porous substance, and contracts like starch in the gelatinous state. The name, however, is unfortunate, as it is generally applied to the solution of gum, and must inevitably lead to confusion. Nor is it strictly a distinct proximate principle; as it embraces a number of different bodies, such as bassorin, cerasin, &c. According to Guérin, the mucilage of flaxseed, obtained at a temperature of from 120° to 140° , and evaporated to dryness, by means of a salt water bath, contains in 100 parts, 52.70 of a principle soluble in cold water, 29.89 of a principle insoluble in that liquid, and 10.30 of water, and yields 7.11 per cent. of ashes. The soluble part he believes to be arabin or pure gum; the insoluble he found not to afford mucic acid with the nitric, and therefore to differ from both bassorin and cerasin. There was also a small proportion of azotized matter which he did not succeed in isolating. (*An. de Chim. et de Phys.* xlix. 263.) Vauquelin found among its constituents free acetic acid, silica, and various salts of potassa and lime.

The interior part of the seed or nucleus is rich in a peculiar oil, which is separated by expression, and very extensively employed in the arts. (See *Oleum Lini*.) The ground seeds are kept in the shops under the name of *flaxseed meal*. This is of a dark gray colour, highly oleaginous, and when mixed with hot water forms a soft adhesive mass, which is much employed for luting by practical chemists. The cake which remains after the expression of the oil, usually called *oil-cake*, still retains the mucilaginous matter of the envelope, and affords a highly nutritious food for cattle. This is the *Lini Farina*, of the Edinburgh Pharmacopœia.

Medical Properties and Uses. Flaxseed is demulcent and emollient. The mucilage obtained by infusing the entire seeds in boiling water, in the proportion of half an ounce to the pint, is much and very advantageously employed in catarrh, dysentery, nephritic and calculous complaints, strangury, and other inflammatory affections of the mucous membranes of the lungs, intestines, and urinary passages. By decoction water extracts also a portion of the oleaginous matter, which renders the mucilage less fit for administration by the mouth, but superior as a laxative enema. The meal mixed with hot water forms an excellent emollient poultice.

LINUM. See LINUM.

Linum catharticum. Willd. *Sp. Plant.* i. 1541; Smith, *Flor. Brit.*

344. This is an annual plant, about six or eight inches high, having erect, slender stems, dichotomous near the summit, furnished with opposite, obovate lanceolate, entire leaves, and bearing minute white flowers, the petals of which are obovate and acute. It is a native of Europe, and not found in the United States, where it is never employed as a medicine.

The whole plant is very bitter and somewhat acrid, and imparts its virtues to water, which acquires a yellow colour. It formerly enjoyed some reputation in Europe as a gentle cathartic, but has fallen into disuse. A drachm of the powder, or an infusion containing the virtues of two or three drachms of the herb, may be taken for a dose. W.

LIRIODENDRON. *U. S. Secondary.**Tulip-tree Bark.*

“The bark of *Liriodendron tulipifera*.” *U. S.*

LIRIODENDRON. *Sex. Syst.* Polyandria Polygynia.—*Nat. Ord.* Magnoliaceæ.

Gen. Ch. Calyx three-leaved. Petals six. Samaræ sublanœolate, one or two-seeded, imbricated in a cone. *Nuttall.*

Liriodendron tulipifera. Willd. *Sp. Plant.* ii. 1254; Bigelow, *Am. Med. Bot.* ii. 107; Barton, *Med. Bot.* i. 92. This noble tree is both from its magnitude and beauty the pride and boast of American landscape. Rising on an erect, straight, cylindrical stem, which is often of nearly equal thickness for the distance of forty feet, it attains, in favourable situations, an elevation seldom less than fifty and sometimes more than one hundred feet, with a diameter of trunk varying from eighteen inches to three feet; and individuals are occasionally met with which greatly exceed these dimensions. The branches, though not very numerous, are thrown out in a somewhat regular order, and give the tree a symmetrical aspect. The bark is of a brown or grayish-brown colour, except in the young branches, on which it is bluish or of a reddish tinge. The leaves, which stand on long footstalks, are alternate, somewhat fleshy, smooth, of a beautiful shining green colour, and divided into three lobes, of which the upper one is truncated and horizontally notched at its summit, so as to present a two-lobed appearance, and the two lower are rounded at the base and usually pointed. In the larger leaves, the lateral lobes have each a tooth-like projection at some distance below their apex. This peculiar form of the leaf serves to distinguish the tree from all others inhabiting the American forests. On isolated trees the flowers are very numerous. They are large, beautifully variegated with different colours, among which the yellow predominates, and in their general appearance bear no inconsiderable resemblance to the tulip, which has given a name to the species. Each flower stands on a distinct terminal peduncle. The calyx is double, the outer being two-leaved and deciduous, the inner consisting of three large, oval, concave

leaves, of a pale green colour. The corolla is composed of six, seven, or more, obtuse, concave petals. The stamens are numerous, with short filaments, and long linear anthers. The pistils are collected into the form of a cone, the upper part of which is covered with minute stigmas. The fruit consists of numerous long, narrow scales, attached to a common axis, imbricated in a conical form, and containing each two seeds, one or both of which are often abortive.

The tulip-tree extends from New England to the borders of Florida, but is most abundant and attains the greatest magnitude in the Middle and Western States. It delights in a rich strong soil, and luxuriates in the exhaustless fertility of the banks of the Ohio and its tributary streams. Throughout the United States it is known by the inappropriate name of *poplar*, for which that of *tulip-tree* is beginning to be substituted. When in full bloom, about the middle of May, it presents in its profusion of flowers, its rich, shining, luxuriant foliage, its elevated stature, and elegant outline, one of the most magnificent objects which the vegetable kingdom affords. The interior or heart wood, which is yellowish, of a fine grain, and compact without being heavy, is much employed in the making of furniture, carriages, door-panels, and for other useful purposes. It is recommended by its property of resisting the influence of atmospheric moisture and the attacks of worms. The bark is the officinal portion. It is taken for use indiscriminately from the root, trunk, and branches, though that derived from the root is thought to be most active.

Deprived of the epidermis, it is of a yellowish-white colour, the bark of the root being somewhat darker than that of the stem or branches. It is very light and brittle, of a feeble, but heavy and rather disagreeable odour, which is stronger in the fresh bark, and of a bitter, pungent, and aromatic taste. These properties are weakened by age; and we have found specimens of the bark which have been long kept in the shops, almost insipid. The peculiar properties of *liriodendron* appear to reside in a volatile principle, which partially escapes during decoction. The late Professor Emmet, of the University of Virginia, believed that he had isolated this principle, and gave it the name of *liriodendrin*. As described by Professor Emmet, it is, in the pure state, solid, white, crystallizable, brittle, insoluble in water, soluble in alcohol and ether, fusible at 180° , volatilizable and partly decomposed at 270° , of a slightly aromatic odour, and a bitter warm pungent taste. It is incapable of uniting with alkalies, which precipitate it from the infusion or decoction of the bark, by combining with the matter which renders it soluble in the water. Neither does it unite with acids. Water precipitates it from its alcoholic solution. It is obtained by macerating the root in alcohol, boiling the tincture with magnesia till it assumes an olive-green colour, then filtering, concentrating by distillation till the liquid becomes turbid, and finally precipitating the *liriodendrin* by the addition of cold water. (*Journ. of the Phil. Col. of Pharm.* iii. 5.) The virtues of the bark are extracted by water and alcohol, but are injured by long boiling.

Medical Properties. *Liriodendron* is a stimulant tonic, with diaphoretic properties. It has been used as a substitute for Peruvian bark in intermittent fevers, and has proved serviceable in chronic rheumatism, dyspepsia, and other complaints, in which a gently stimulant and tonic impression is desirable. The dose of the bark in powder is from half a drachm to two drachms. The infusion and decoction are also used, but are less efficient. They may be prepared in the proportion of an ounce of the bark to a pint of water, and given in the quantity of one or two fluidounces. The dose of the saturated tincture is a fluidrachm.

W.

LOBELIA. U.S., Lond., Ed.

Lobelia.

“*Lobelia inflata*.” U.S., Lond. “Herb of *Lobelia inflata*.” Ed.

LOBELIA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Lobeliaceæ.

Gen. Ch. *Calyx* five-cleft. *Corolla* irregular, five-parted, cleft on the upper side nearly to the base. *Anthers* united into a tube. *Stigma* two-lobed. *Capsule* inferior or semi-superior, two or three-celled, two-valved at the apex. *Torrey*.

Lobelia inflata. Willd. *Sp. Plant.* i. 946; Bigelow, *Am. Med. Bot.* i. 177; Barton, *Med. Bot.* i. 181. This species of *Lobelia*, commonly called *Indian tobacco*, is an annual or biennial indigenous plant, usually a foot or more in height, with a fibrous root, and a solitary, erect, angular, very hairy stem, much branched about midway, but rising considerably above the summits of the highest branches. The leaves are scattered, sessile, oval, acute, serrate, and hairy. The flowers are numerous, small, disposed in leafy terminal racemes, and supported on short axillary footstalks. The segments of the calyx are linear and pointed. The corolla, which is of a delicate blue colour, has a labiate border, with the upper lip divided into two, the lower into three acute segments. The united anthers are curved, and enclose the stigma. The fruit is an oval, striated, inflated capsule, crowned with the persistent calyx, and containing, in two cells, numerous very small, brown seeds.

The *Lobelia inflata* is a very common weed, growing on the road-sides, and in neglected fields, throughout the United States. Its flowers begin to appear towards the end of July, and continue to expand in succession till the occurrence of frost. The plant when wounded or broken exudes a milky juice. All parts of it are possessed of medicinal activity; but, according to Dr. Eberle, the root and inflated capsules are most powerful. The plant should be collected in August or September, when the capsules are numerous, and should be carefully dried. It may be kept whole, or in the state of powder. As found in the shops, it is often in oblong compressed cakes, prepared by the Shakers.

Dried lobelia has a slight irritating odour, and when chewed, though at first without much taste, soon produces a burning acrid impression upon the posterior parts of the tongue and palate, very closely resembling that occasioned by tobacco, and attended, in like manner, with a flow of saliva and a nauseating effect upon the stomach. The powder is of a greenish colour. The plant yields its active properties readily to water and alcohol. Water distilled from it, according to Mr. Procter, has the odour of the plant, without its acrimony. Mr. Procter found the plant to contain an odorous volatile principle, probably volatile oil; a peculiar alkaline principle named *lobelina*; a peculiar acid first noticed as distinct by Pereira, called *lobelic acid*; besides gum, resin, chlorophylle, fixed oil, lignin, salts of lime and potassa, and oxide of iron. The seeds contain at least twice as much of *lobelina*, in proportion, as the whole plant, which yielded only one part in five hundred. They contain also thirty per cent. of a nearly colourless fixed oil, having the drying property in an extraordinary degree. *Lobelina* was obtained by Mr. Procter from the seeds by the following process. The seeds were treated with alcohol acidulated with acetic acid, until deprived of their acrimony, and the tincture was evaporated; the resulting extract was triturated with magnesia and water, and, after repeated agitation for several hours, the liquor,

holding lobelina in solution, was filtered; this was then shaken repeatedly with ether until deprived of acrimony; and the ethereal solution, having been decanted, was allowed to evaporate spontaneously. The residue, which had a reddish-brown colour, and the consistence of honey, was deprived of colouring matter by dissolving it in water, adding a slight excess of sulphuric acid, boiling with animal charcoal, saturating with magnesia, filtering, agitating with ether until this fluid had deprived the water of acrimony, and finally decanting, and allowing the ether to evaporate. Thus obtained, *lobelina* is a yellowish liquid, lighter than water, of a somewhat aromatic odour, and a very acrid durable taste. It is soluble in water, but much more copiously in alcohol and ether, and the latter fluid readily removes it from its aqueous solution. It has a decided alkaline reaction, and forms soluble and crystallizable salts with sulphuric, nitric, and muriatic acids, and a very soluble but not crystallizable salt with acetic acid. It forms an insoluble compound with tannic acid, which instantly precipitates it from its solution. By a boiling heat it is entirely decomposed, losing all its acrimony; but, when combined with acids, it may be subjected to ebullition with water without change. M. Procter introduced a grain of it diluted with water into the stomach of a cat, which became immediately prostrate, remained for an hour nearly motionless, with dilated pupils, and had not recovered wholly from the prostrating influence of the poison at the end of fifteen hours. It did not occasion vomiting or purging. There can be little doubt that it is the narcotic principle of lobelia. (*Am. Journ. of Pharm.* ix. 105, and xiii. 1.) The late Dr. S. Colhoun, of Philadelphia, was the first to announce the existence of a peculiar active principle in lobelia, capable of forming salts with the acids; but he did not obtain it in an isolated state. An important inference from the effects of heat upon lobelina is that, in any of the preparations of lobelia, the plant should never be heated in connexion with a salifiable base.

Medical Properties and Uses. Lobelia is emetic, and like other medicines of the same class is occasionally cathartic, and in small doses diaphoretic and expectorant. It is also possessed of narcotic properties. The leaves or capsules, chewed for a short time, occasion giddiness, headache, general tremors, and ultimately nausea and vomiting. When swallowed in the full dose, the medicine produces speedy and severe vomiting, attended with continued and distressing nausea, copious sweating, and great general relaxation. Its effects in doses too large or too frequently repeated, are extreme prostration, great anxiety and distress, and ultimately death preceded by convulsions. Fatal results have been experienced from its empirical use. These are more apt to occur when the poison, as sometimes happens, is not rejected by vomiting. In its operation upon the system, therefore, as well as in its sensible properties, lobelia bears a close resemblance to tobacco. It is among the medicines which were employed by the aborigines of this country; and was long in the hands of empirics before it was introduced into regular practice. The Rev. Dr. Cutler of Massachusetts first attracted to it the attention of the profession.

As an emetic it is too powerful, and too distressing as well as hazardous in its operation for ordinary use. The disease in which it has proved most useful is spasmodic asthma, the paroxysms of which it often greatly mitigates, and sometimes wholly relieves, even when not given in doses sufficiently large to produce active vomiting. It was from the relief obtained from an attack of this complaint in his own person, that Dr. Cutler was induced to recommend the medicine. It has also been used in catarrh, croup, pertussis, and other laryngeal and pectoral affections; and we have

seen it apparently advantageous in some of these complaints, especially in severe croup; but it should always be used with caution. Administered by injection it produces the same distressing sickness of stomach, profuse perspiration, and universal relaxation, as result from a similar use of tobacco. Dr. Eberle administered a strong decoction of it successfully by the rectum, as a substitute for this narcotic in a case of strangulated hernia. It has been employed effectually, in small doses repeated so as to sustain a slight nausea, for producing relaxation of the os uteri. (*Am. Journ. of Med. Sci.* xvii. 248.)

It may be given in substance, tincture, or infusion. The dose of the powder as an emetic is from five to twenty grains, to be repeated if necessary. The tincture is most frequently administered. The full dose of this preparation for an adult is half a fluidounce, though in asthmatic cases it is better administered in the quantity of one or two fluidrachms, repeated every two or three hours till its effects are experienced.

Two other species of Lobelia have attracted some attention from medical writers. The *L. cardinalis* or *cardinal flower*, distinguished for its showy red flowers, is supposed to possess anthelmintic properties; but is seldom or never used. The *L. syphilitica* is said to have been used by the Indians in the cure of the venereal disease, but has upon trial been found wholly inefficacious in that complaint. It is emetic and cathartic, and appears also to possess diuretic properties, whence it has been conjectured that it might have proved serviceable in gonorrhœa. Dr. Chapman states that it has been employed, as he has been informed, by some practitioners of the western country in dropsy, and not without success. The root is the part used. Both these species of Lobelia are indigenous. For a more detailed account of them the reader is referred to Dr. W. P. C. Barton's Medical Botany.

LYCOPUS. U. S. Secondary.

Bugle-weed.

“The herb of *Lycopus Virginicus*.” U. S.

LYCOPUS. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Lamiaceæ or Labiatae.

Gen. Ch. Calyx tubular, five-cleft or five-toothed. Corolla tubular, four-lobed, nearly equal; the upper segment, broader, and emarginate. Stamens distant. Seeds four, naked, retuse. *Nuttall.*

Lycopus Virginicus. Michaux, *Flor. Boreal. Americ.* i. 14; Rafinesque, *Med. Flor.* vol. ii. The *bugle-weed* is an indigenous herb, with a perennial creeping root, which sends up an erect, nearly simple, obtusely quadrangular stem, from twelve to eighteen inches high, and furnished with opposite, sessile leaves. These are broad lanceolate, attenuated and entire at both extremities, remotely serrate in the middle, somewhat rough, pur-

plish, and beset with glandular dots on their under surface. The flowers are minute, in small axillary whorls, with two small subulate bractes to each flower, and a white corolla. The seeds are longer than the calyx, which is spineless.

This plant grows in shady and wet places throughout the greater part of the United States. Its flowering period is August. The whole herb is used. It has a peculiar odour, and a nauseous slightly bitter taste, and imparts these properties, as well as its medical virtues, to boiling water.

The *L. Europæus* is said to be frequently collected and sold for the *L. Virginicus*. The former may be distinguished by its acutely quadrangular stem, its narrow-lanceolate leaves of which the lower are somewhat pinnatifid, its more crowded flowers, and the acute segments of its calyx, armed with short spines.

Medical Properties and Uses. According to Dr. A. W. Ives, the bugleweed is a very mild narcotic. It was introduced into notice by Drs. Pendleton and Rogers, of New York, who obtained favourable effects from its use in insipient phthisis and hemorrhage from the lungs. (*N. Y. Med. and Phys. Journ.* i. 179.) In these complaints it is useful by diminishing the frequency of the pulse, quieting irritation, and allaying cough. It is most conveniently taken in the form of infusion, which may be prepared by macerating an ounce of the herb in a pint of boiling water, and drunk ad libitum. W.

LYTHRUM SALICARIA. Herba. *Dub.*

Loosestrife. Purple Willow-herb.

Salicaire, *Fr.*; Rother Weiderich, *Germ.*; Salicaria, *Ital.*

LYTHRUM. *Sex. Syst.* Dodecandria Monogynia.—*Nat. Ord.* Lythraceæ.

Gen. Ch. Calyx twelve-toothed. Petals six, inserted into the calyx.

Capsule two-celled, many-seeded. *Willd.*

Lythrum Salicaria. Willd. *Sp. Plant.* ii. 865. Loosestrife is an elegant perennial plant, two or three feet high, with an erect, quadrangular or hexagonal, downy, herbaceous stem, bearing opposite, ternate, sessile, lanceolate leaves, cordate at the base, and downy on the under surface and at the margin. The flowers are axillary, forming a leafy verticillate spike. The calyx is red, with unequal segments, the petals purple and undulate, the fruit a small elliptical capsule.

The plant grows wild in all parts of Europe, and is found in New England and Canada. It prefers meadows, swamps, and the banks of streams, which it adorns in July and August with its showy purple flowers. The whole herbaceous part is medicinal, and is dried for use.

In this state it is inodorous, and has an herbaceous somewhat astringent taste. It renders boiling water very mucilaginous, and its decoction is blackened by the sulphate of iron.

Medical Properties and Uses. Loosestrife is demulcent and astringent; and may be advantageously given in diarrhœa and chronic dysentery after due preparation by evacuating treatment. It has long been used in Ireland in these complaints, and is said to be a popular remedy in Sweden. The dose of the powdered herb is about a drachm two or three times a day. A decoction of the root prepared by boiling an ounce in a pint of water may be given in the dose of two fluidounces. W.

MAGNESIÆ CARBONAS. U.S., Lond., Ed., Dub.

Carbonate of Magnesia.

Magnesia alba, *Lat.*; Carbonate de magnésie, *Fr.*; Kohlensaure Magnesia, *Germ.*; Carbonato di magnesia, *Ital.*; Carbonato de magnesia, *Span.*

Carbonate of magnesia sometimes though rarely occurs as a native mineral. That which is sold in the shops is prepared on a large scale by the manufacturer, and the article is, therefore, very properly placed in the list of *Materia Medica* of the United States Pharmacopœia. The British Colleges still retain it among the preparations, and the London and Edinburgh Colleges direct it to be prepared by decomposing the sulphate of magnesia with carbonate of soda; and the Dublin College, by decomposing the same salt with carbonate of potassa. The *London College* dissolves four pounds eight ounces of carbonate of soda, and four pounds of sulphate of magnesia, separately, in two gallons (*Imp. Meas.*) of distilled water; then mixes the solutions, boils for fifteen minutes, constantly stirring with a spatula; and lastly, pours off the liquor, washes the precipitated powder with boiling distilled water, and dries it. The *Edinburgh* formula is substantially the same. The directions differ only in using water, instead of distilled water, and in collecting the precipitate on a filter of calico or linen. The *Dublin College* dissolves twenty-five parts of sulphate of magnesia and fourteen parts of carbonate of potassa, each in two hundred parts of boiling water, mixes the solutions, boils, filters, and washes the precipitate well with boiling water.

The carbonate of potassa is not as advantageously used as the carbonate of soda for the preparation of carbonate of magnesia. It is difficult to separate the last portions of sulphate of potassa from the precipitate, and the carbonate of potassa usually contains silica, which is thrown down with the magnesia. The consequence is, that when prepared with that salt, the carbonate of magnesia is liable to be gritty to the touch and to have a saline taste. The following is said to be the method pursued by some of the best manufacturers. To a saturated solution of one hundred parts of sulphate of magnesia, a solution of one hundred and twenty-five parts of crystallized carbonate of soda is gradually added, the solutions being constantly stirred. The mixture is then heated to ebullition, to complete the precipitation of the magnesia, which is then washed with tepid and finally with cold water, until the washings no longer give a precipitate with the barytic salts. When it is sufficiently washed, the carbonate is allowed to drain for one or two days on large linen filters, and is then placed in wooden moulds with a porous bottom of brick or gypsum, and subjected to pressure in order to give it the square and compact form into which it is usually wrought.

The density of carbonate of magnesia is said to depend upon the strength of the solutions from which it is first precipitated, and its fineness and softness to the touch, upon the use of carbonate of soda in its preparation.

The principal part of the carbonate of magnesia used in this country is imported from Scotland. In the New England States it is prepared from the bittern of salt works, which consists chiefly of sulphate of magnesia and chloride of magnesium; and it is manufactured in Baltimore from the sulphate of magnesia prepared in that city. The Scotch magnesia is generally put up in cases of one hundred and twenty pounds each, the American in boxes containing fifty pounds.

We have spoken of the impurities which carbonate of magnesia prepared

by the officinal process is apt to contain. When made from the bittern of salt works, it is contaminated with carbonate of lime, salts of that earth being contained in sea-water; and when it is prepared from magnesite, or from magnesian schist, iron is almost always present. The only way in which these impurities can be avoided, is to prepare pure sulphate of magnesia by repeated crystallization, and to use a pure carbonate of soda. It is also necessary that the water with which the precipitate is washed should be free from earthy salts, which would be decomposed and contaminate the magnesia.

Properties. Carbonate of magnesia is inodorous, nearly insipid, perfectly white, smooth to the touch, and nearly insoluble in water, requiring 2493 parts of cold, and 9000 parts of hot water for solution. It is decomposed by a strong heat, by all the acids, by potassa, soda, lime, baryta, and strontia, and by acidulous and metallic salts.

Two kinds of carbonate of magnesia are distinguished, the light and the heavy. The *light carbonate* is the kind manufactured in Scotland. The *heavy*, according to Dr. Pereira, may be manufactured as follows:—"Add one volume of a cold saturated solution of carbonate of soda to a boiling mixture of one volume of a saturated solution of sulphate of magnesia, and three volumes of water. Boil until effervescence has ceased, constantly stirring with a spatula. Then dilute with boiling water, set aside, pour off the supernatant liquor, and wash the precipitate with hot water on a linen cloth: afterwards dry it by heat in an iron pot."

A solution in carbonic acid water, prepared by passing carbonic acid gas into a reservoir containing the carbonate of magnesia suspended in water, has been introduced into use as a cathartic and antacid; but is in no respect preferable to the undissolved carbonate, while it is more unpleasant to the taste. *Dinneford's magnesia* is a solution of this nature. According to Dr. Christison's analysis, it contains only nine grains of carbonate in the fluid-ounce, though it is alleged to contain twice that quantity.

Adulterations and Tests. Carbonate of magnesia may contain an alkaline carbonate, or an alkaline sulphate, or both, from insufficient washing; also chloride of sodium, alumina, and carbonate of lime. If water boiled on it changes turmeric, an alkaline carbonate is indicated. If chloride of barium produces a precipitate in the water, the presence of a sulphate or carbonate, or both, is shown, and if nitrate of silver produces the same effect, a chloride is indicated. When dissolved in an excess of muriatic acid, an excess of ammonia will throw down alumina, which is scarcely ever absent in minute quantity; and oxalate of ammonia, afterwards added to the filtered muriatic solution, will throw down lime as oxalate of lime, if that earth be present.

Composition. According to Berzelius, the carbonate of magnesia of the shops (*magnesia alba*) is a combination of three equivalents of carbonate of magnesia with one of hydrate of magnesia. Each eq. of carbonate contains an eq. of water, and the composition of the salt may be thus stated:—three equivalents of carbonate (acid 66·36, magnesia 62·1, water 27) = 155·46 + one equivalent of hydrate (magnesia 20·7, water 9) = 29·7 = 185·16. This theoretic composition agrees very nearly with the analysis of Berzelius, who fixes it at 44·75 magnesia, 35·77 acid, and 19·48 water.

The composition of this salt varies with the mode of preparation. Thus Buchholz, by decomposing the sulphate of magnesia with 170 per cent. of carbonate of soda, and using only cold water throughout, obtained a very light, spongy, somewhat coherent magnesia, containing 32 acid, 33 base, and 35 water. By using 120 per cent. of the carbonate, and boiling the

water for fifteen minutes, he obtained a heavy granular precipitate containing 35 acid, 42 base, and 23 water.

Medical Properties and Uses. Carbonate of magnesia is antacid, and by combining with acid in the stomach, becomes generally cathartic. When it undergoes no change in the alimentary canal, it produces no purgative effect. Under these circumstances, it may usually be made to operate by following it with draughts of lemonade. It is useful in all cases which require a laxative antacid; and, though apt to produce flatulence in consequence of the extrication of its carbonic acid in the stomach and bowels, and therefore in ordinary cases inferior to calcined magnesia, it sometimes operates favourably, in consequence of this very property, in sick stomach attended with acidity. Carbonate of magnesia is also an excellent antilithic in those cases in which uric acid is secreted in too great abundance.

The dose is from half a drachm to two drachms, which may be given suspended in water or milk. In order that it may be accurately diffused through water, it should be previously rubbed down with simple syrup or ginger syrup.*

Carbonate of magnesia is a useful agent for diffusing camphor and the volatile oils through water, in preparing several of the medicated waters. (See *Aquæ Medicatæ*.)

MAGNESIÆ SULPHAS. *U. S., Lond., Ed., Dub.*

Sulphate of Magnesia.

Epsom salt; Sulfate de magnésie, *Fr.*; Schwefelsaure Magnesia, *Germ.*; Solfato di magnesia, *Ital.*; Sulfato de magnesia, *Span.*

Sulphate of magnesia is one of the constituents of sea-water, and of some saline springs. It also occurs native, either crystallized in long, slender, prismatic, adhering crystals, or as an efflorescence on certain rocks and soils, which contain magnesia and a sulphate or sulphuret. In the United States it is found abundantly in the great caverns, so numerous to the west of the Alleghany mountains. In one of those caves, near Corydon in Indiana, it forms a stratum on the bottom several inches deep; or appears in masses sometimes weighing ten pounds; or is disseminated in the earth of the cavern, one bushel of which yields from four to twenty-five pounds of this sulphate. It also appears on the walls of the cavern, and, if it be removed, acicular crystals again appear in a few weeks. (*Cleveland.*)

Sulphate of magnesia was originally procured by evaporating the waters of some saline springs at Epsom in England. Dr. Grew prepared it in this manner in 1675. It was afterwards discovered that the brine remaining after the crystallization of common salt from sea-water, furnished by careful evaporation precisely the same salt; and as this was a much cheaper product it superseded the former. This residual brine or bitter consists of sulphate of magnesia and the chlorides of magnesium and calcium. As the sulphate of magnesia crystallizes first, it may with proper care be obtained nearly pure, although most frequently the salt prepared in this way is deliquescent from being contaminated with the chloride of magnesium. It may

* *Dalby's Carminative* consists of carbonate of magnesia ℥ij, oil of peppermint ℥j, oil of nutmeg ℥ij, oil of aniseed ℥ij, tincture of castor ℥xxx, tincture of assafetida ℥xv, tincture of opium ℥v, spirit of pennyroyal ℥xv, compound tincture of cardamom ℥xxx, peppermint water fʒij.

be purified from this mixture by washing the crystals with its own saturated solution. It was from this source that the greater part of the Epsom salt of commerce was long obtained in Europe. The salt works of New England supplied our own markets with an impure and deliquescent sulphate. With the improvements of chemistry, other and better processes have latterly been adopted. In the neighbourhood of Genoa and of Nice, in Italy, sulphate of magnesia is prepared in large quantities from a schistose rock, which contains magnesia and sulphuret of iron. The mineral is roasted and exposed in heaps for some months to the combined action of air and water. It is then lixiviated, the sulphate of iron decomposed by lime-water, and the salt is obtained pure by repeated solution and crystallization.

William Henry of Manchester, whose calcined magnesia has become famous throughout the world, took out a patent for a mode of preparing magnesia and its salts from the double carbonate of magnesia and lime—the dolomite of mineralogists. His process was to drive off the carbonic acid by heat, and to convert the remaining earths into hydrates. He treated these with a sufficient quantity of muriatic acid to dissolve out the lime, and then converted the magnesia into a sulphate either by sulphuric acid or sulphate of iron.

This salt is extensively manufactured at Baltimore from the siliceous hydrate of magnesia, or magnesite. This mineral occurs in veins in the serpentine and other magnesian rocks which abound in the neighbourhood of that city, and in the southern counties of Pennsylvania. The advantage which it possesses over the dolomite, in the preparation of this salt, is the almost entire absence of lime, owing to which circumstance there is little or no waste of acid, and the operation is much simplified. The mineral is reduced to a fine powder, and saturated with sulphuric acid. The mass is then dried and calcined at a red heat, in order to convert the sulphate of iron which may be present into red oxide. It is then dissolved in water, and sulphuret of lime added to separate any remaining portion of iron. The salt is crystallized and dissolved a third time, in order to purify it. The sulphate prepared at the Baltimore works by this process is generally very pure and clean, although it sometimes contains sulphate of iron.

Properties, &c. Sulphate of magnesia is a colourless transparent salt, without smell, and of a bitter, nauseous, saline taste. It crystallizes in quadrangular prisms, terminating in a four-sided pyramid or in a dihedral summit. It usually occurs in small acicular crystals. It slowly effloresces in the air. At 32° of Fahrenheit, 100 parts of water dissolve 25·76 parts of the anhydrous salt, and for every increased degree of heat 0·8597 parts additional are taken up. The crystals contain 51·22 per cent. of water of crystallization, and dissolve in their own weight of water at 60°, and in three-fourths of their weight of boiling water. They melt in their water of crystallization, and at a high temperature fuse into an enamel. (*Berzelius.*) This salt consists of one equivalent of acid = 40·1, one of base = 20·7, and seven of water = 63; and its combining number is 123·8.

Sulphate of magnesia is completely decomposed by potassa, soda, and their carbonates; by lime, baryta and strontia, and their soluble salts. Ammonia partially decomposes it, and forms with the remaining salt a double sulphate. The bicarbonates of potassa and soda do not decompose the sulphate of magnesia, except by the aid of heat.

Sulphate of magnesia is liable to contain iron and chloride of magnesium, the former of which may be detected by ferrocyanuret of potassium, and the latter by its rendering the salt moist. If the addition of sulphuric acid produce no extrication of muriatic acid gas, the fact proves the absence of all

chlorides. One hundred grains of an aqueous solution of the salt, should yield, when completely decomposed by a boiling solution of carbonate of soda, thirty-four grains of dry carbonate of magnesia. If the dry precipitate be less, the specimen tested is not all sulphate of magnesia, and probably contains sulphate of soda.

Medical Properties and Uses. Sulphate of magnesia is a mild and safe cathartic, operating with little pain or nausea, and producing watery stools. It is more acceptable to the stomach than most medicines of its class, and will often be retained when others are rejected. Like many of the other neutral salts it is refrigerant, and may be made to act as a diuretic, by keeping the skin cool and walking about after it has been taken. It is well adapted to the treatment of fevers and inflammatory affections, especially after a previous thorough evacuation of the bowels by a more energetic cathartic. It is also useful in colic and obstinate constipation, and may be employed in most cases which require the use of a cathartic, without being attended with debility or relaxation of the stomach and bowels. The medium dose is an ounce; but advantage often results from its administration in divided doses frequently repeated. It is often given in combination with other medicines, especially with senna, the griping effect of which it tends to obviate. The pleasantest form for administering the salt, and that in which it usually agrees best with the stomach, is a solution in carbonic acid water with lemon syrup. By Dr. Henry of Dublin it is highly recommended in connexion with sulphuric acid. To seven ounces of the saturated aqueous solution of the salt he adds an ounce of the diluted sulphuric acid of the Pharmacopœias, and gives a tablespoonful of the mixture for a dose, in a wineglassful of water.

MAGNOLIA. U.S. Secondary.

Magnolia.

“The bark of *Magnolia glauca*, *Magnolia acuminata*, and *Magnolia tripetala*.” U. S.

MAGNOLIA. Sex. Syst. Polyandria Polygynia.—*Nat. Ord.* Magnoliaceæ.

Gen. Ch. Calyx three-leaved. Petals six or more. Capsules two-valved, one-seeded, imbricated in a cone. Seeds berried, pendulous. *Bigelow.*

The medicinal properties which have rendered the bark of the *Magnolia officinalis*, are common to most, if not all of the species composing this splendid genus. Among the numerous trees which adorn the American landscape, these are most conspicuous for the beautiful richness of their foliage, and the magnificence as well as delicious odour of their flowers; and the *M. grandiflora* of the Southern States rivals in magnitude the largest inhabitants of our forests. The Pharmacopœia designates the *M. glauca*, *M. acuminata*, and *M. tripetala*, each of which we shall briefly describe.

1. *Magnolia glauca*. Willd. *Sp. Plant.* ii. 1256; *Bigelow, Am. Med. Bot.* ii. 67; Barton, *Med. Bot.* i. 77; Michaux, *N. Am. Sylv.* ii. 8. This species of *Magnolia*, which in the Northern States is often nothing more than a shrub, sometimes attains in the South the height of forty feet. The leaves are scattered, petiolate, oval, obtuse, entire, glabrous, thick, opaque, yellowish-green on their upper surface, and of a beautiful pale glaucous colour beneath. The flowers are large, terminal, solitary, cream-coloured, strongly and gratefully odorous, often scenting the air to a considerable dis-

tance. The calyx is composed of three leaves; the petals, from eight to fourteen in number, are obovate, obtuse, concave, and contracted at the base; the stamens are very numerous, and inserted on a conical receptacle; the germs are collected into a cone, and each is surmounted by a linear recurved style. The fruit is conical, about an inch in length, consisting of numerous imbricated cells, each containing a single scarlet seed. This escapes through a longitudinal opening in the cell, but remains for some time suspended from the cone by a slender thread to which it is attached.

The *M. glauca* extends along the seaboard of the United States, from Cape Ann in Massachusetts to the shores of the Gulf of Mexico. It is abundant in the Middle and Southern States, usually growing in swamps and morasses; and is seldom met with in the interior of the country west of the mountains. It begins to flower in May, June, or July, according to the latitude. It is known by the name of *magnolia* simply in the Northern and Middle States, by that of *white bay* or *sweet bay* in the South, and is occasionally called *swamp sassafras*, *beaver tree*, &c.

2. *M. acuminata*. Willd. *Sp. Plant.* ii. 1257; Michaux, *N. Am. Sylv.* ii. 12. This species is much larger than the preceding, often growing to the height of seventy or eighty feet. The leaves are six or seven inches long, by three or four in breadth, oval, acuminate, and pubescent on their under surface. The flowers are five or six inches in diameter, bluish or cream-coloured, slightly odorous, with obovate rather obtuse petals from six to nine in number. Mingled with the splendid foliage, they give a magnificent aspect to the tree when large and in full bloom. The tree grows in the mountainous regions in the interior of the United States, extending along the Alleghanies from the state of New York to their termination in Georgia, and seldom existing in the low country far either to the east or the west of this range. Wherever it is found, it is called *cucumber tree*, from the resemblance of its fruit in shape and size to this product of the gardens.

3. *M. tripetala*. Willd. *Sp. Plant.* ii. 1258; Michaux, *N. Am. Sylv.* ii. 18. This is a small tree, sometimes though rarely reaching an elevation of thirty feet, and almost always having an inclined trunk. It is remarkable for the size of its leaves and flowers. The former are eighteen or twenty inches long by seven or eight in breadth, thin, obovate, somewhat wedge-shaped, entire, acute at both extremities, pubescent when young, and often disposed in rays at the extremity of the shoots, displaying a surface thirty inches in diameter. Hence has arisen the name of *umbrella tree*, by which this species is distinguished. The flowers are terminal, seven or eight inches in diameter, white, with from five to twelve oval acute petals, of which the three outer are reflexed. This species extends from the northern parts of New York to the southern limits of the United States. It is found only in situations which are shady, with a strong, deep, and fertile soil. It is common in some of the islands of the Susquehanna, and still more so in the Southern and South Western States. (*Michaux.*)

The bark and fruit of all the species of *Magnolia* are possessed of similar medicinal properties; but the bark only is officinal; and that of the root is thought to be most efficient. It has an aromatic odour, and a bitter, pungent, spicy taste. The aromatic property, which resides in a volatile principle, is diminished by desiccation, and entirely lost when the bark is long kept. The bitterness, however, remains. The bark is destitute of astringency. The bark of the *Magnolia grandiflora*, examined by Dr. Stephen Procter, was found to contain volatile oil, resin, and a principle analogous to the liriodendrin of Professor Emmet. (*Am. Journ. of Pharm.*

xiv. 95.) It is probable that the bark of the other species contains similar ingredients.

Medical Properties and Uses. Magnolia is a gently stimulant aromatic tonic and diaphoretic, useful in chronic rheumatism, and capable, if freely given, of arresting the paroxysms of intermittent fever. It has been used advantageously in these complaints, and in remittents, especially of a typhoid character. The dose of the recently dried bark in powder is from half a drachm to a drachm, frequently repeated. The infusion may also be used, but is less efficient. Diluted alcohol extracts all the virtues of the medicine; and a tincture, made by macerating the fresh bark or cones in brandy, is a popular remedy in chronic rheumatism. W.

MALVA. *Lond., Ed.*

Common Mallow.

“*Malva sylvestris.*” *Lond.* “Herb of *Malva sylvestris.*” *Ed.*

Mauve sauvage, *Fr.*; Waldmalve, *Germ.*; Malva, *Ital., Span.*

MALVA. *Sex. Syst.* Monadelphia Polyandria.—*Nat. Ord.* Malvaceæ.

Gen. Ch. Calyx double, the exterior three-leaved. Capsules very many, one-seeded. *Willd.*

Malva sylvestris. Willd. *Sp. Plant.* iii. 787; *Woodv. Med. Bot.* p. 554. t. 197. This is a perennial, herbaceous plant, with a round, hairy, branching, usually erect stem, from one to three feet high, bearing alternate, petiolate, cordate, roughish leaves, which are divided into five or seven crenate lobes, and on the upper part of the stem are almost palmate. The flowers are large, purplish, and placed from three to five together at the axils of the leaves, upon long slender peduncles, which, as well as the petioles, are pubescent. The petals are five, inversely cordate, and three times as long as the calyx. The capsules are disposed compactly in a circular form.

This species of mallow is a native of Europe, where it grows abundantly on waste grounds and by the way-sides, flowering from May to August. It is sometimes cultivated in our gardens. Other species, indigenous or naturalized in this country, are possessed of the same properties, which are in fact common to the whole genus. The *M. rotundifolia* is one of the most common, and may be substituted for the *M. sylvestris*.

The herb and flowers, which are the officinal parts, have a weak, herbaceous, slimy taste, without odour. They abound in mucilage, which they readily impart to water; and the solution is precipitated by acetate of lead. The infusion and tincture of the flowers are blue, and serve as a test of acids and alkalies, being reddened by the former, and rendered green by the latter. The roots and seeds are also mucilaginous.

Medical Properties and Uses. Common mallow is emollient and demulcent. The infusion and decoction are sometimes employed in catarrhal, dysenteric, and nephritic complaints; and are applicable to all other cases which call for the use of mucilaginous liquids. They are also used as an emollient injection; and the fresh plant forms a good suppurative or relaxing cataplasm in external inflammation. It was formerly among the culinary herbs.

MANGANESII OXIDUM. *Ed.**Oxide of Manganese.*

Off. Syn; MANGANESII BINŌXYDUM. *Lond.;* MANGANESII OXYDUM. *Dub.*

Manganese, Peroxide of manganese, Deutoxide of manganese, Black oxide of manganese; Oxide noir de manganese, *Fr.;* Braunstein, *Germ.;* Manganese, *Ital., Span.*

Black oxide of manganese is the deutoxide or binoxide of a peculiar metal properly called manganese; though this name is commonly applied to the oxide itself. *Metallic manganese* was discovered by Scheele and Gahn in 1774, and is obtained from the native black oxide by intense ignition with charcoal. It is hard, brittle, granular, of a grayish-white colour, and emits a disagreeable odour in a moist atmosphere. It oxidizes readily by the action of the air, first tarnishing, then assuming a yellowish or violet colour, and finally becoming converted into a black powder. Its sp. gr. is 8, melting point 160° of Wedgwood, and equivalent number 27.7. With oxygen it forms five combinations, three regular oxides and two acids. The *protoxide* is of a light green colour, and is the oxide present in the salts of manganese. The *sesquioxide* is black or dark brown, and the *deutoxide* black. The two acids are formed by the action of potassa on the deutoxide, and are called *manganic* and *hypermanganic acid*. Assuming one equiv. of manganese in each of these combinations, the protoxide is found to contain one, the sesquioxide one and a half,* the deutoxide two, manganic acid three, and hypermanganic acid three and a half equivalents of oxygen. (*Berzelius.*) Besides these, there exist a double oxide, of a brownish-red colour, called the *red oxide*, consisting of one equiv. of protoxide and one of sesquioxide, and invariably formed when any one of the other oxides of manganese is exposed to a white heat; and a native oxide, called *Varvicite*, composed of two equiv. of deutoxide, and one of sesquioxide. Metallic manganese is an occasional constituent of organic matter. It was detected in minute quantity in bones by Fourcroy and Vauquelin, and is often present in the ashes of plants. In the mineral kingdom, it occurs sometimes as a sulphuret, rarely as a phosphate, but very abundantly as the black or deutoxide. It is this latter mineral which constitutes the official oxide.

Properties. Deutoxide of manganese, as it occurs in nature, is very variable in its appearance. It is found sometimes in brilliant needle-shaped crystals, often in compact masses having the metallic lustre, but far more frequently in the form of a dull earthy looking substance of a black or brown colour. It is purest when crystallized. As it occurs in commerce it is usually in the form of powder, of a black colour, insoluble in water, and containing as impurities more or less oxidized iron, carbonate of lime, sulphate of baryta, and earthy matter. Iron, which is rarely absent, is detected by the production of a greenish or blue tint on the addition of ferrocyanuret of potassium. When exposed to a red heat it yields a considerable quantity of oxygen, and is reduced to the state of sesquioxide. Hence its use in obtaining that gas. When dried, and afterwards heated to whiteness, good samples lose twelve per cent. of oxygen. (*Lond. Pharm.*) It is distinguished from the sulphuret of antimony by its infusibility, and by its causing the

* In order to avoid fractional equivalents, the sesquioxide is generally stated to consist of two equiv. of metal, and three of oxygen, which is the same proportion as that given in the text.

evolution of chlorine on being heated with muriatic acid. When of a brown colour, it is not of good quality. Its composition has been given above.

But few mines of deutoxide of manganese exist, though the metal itself is very generally diffused throughout the mineral kingdom. It occurs most abundantly in Bohemia, Saxony, the Hartz, France, and Great Britain. In the United States no mines have been opened, except in Vermont, from which state an inferior brown ferruginous manganese is supplied through Boston. Besides this source of supply, the mineral is received from Nova Scotia, France, Germany, England, and occasionally Scotland. It comes packed in casks or barrels, generally in lumps and coarse powder, just as it is dug out of the mines; though occasionally it is received from England ready pulverized. It is a good rule to buy it unpowdered, as its quality can be better judged of in that state. A dark shining crystalline appearance may be taken as an indication of good quality. The Nova Scotia manganese is better than the Vermont; but that received from Germany and England is the best, and commands the highest price in the market. The Scotch manganese is also of good quality.

Medical Properties and Uses. The physiological effects of the preparations of manganese are but imperfectly known. Manganic acid, given to a rabbit, seemed to increase the urine. C. G. Gmelin found the sulphate of the protoxide to produce an extraordinary secretion of bile when exhibited to animals. According to Dr. Thomson, of Glasgow, it acts on man as a purgative, resembling sulphate of soda both in taste and effect. The black oxide is deemed a tonic by some experimenters. When slowly introduced into the system, as happens to those engaged in grinding the mineral, it acts, according to Dr. Coupar, of Glasgow, as a cumulative poison, inducing a disease which first shows itself by a staggering gait, and ends in paraplegia. It has been used in syphilis, chlorosis, scurvy, and various skin diseases, especially itch and porrigo. The dose is from three to twenty grains, three times a day, given in the form of pill. For external use, the ointment is made of one or two drachms of the oxide to an ounce of lard.

Black oxide of manganese is used in the arts for obtaining chlorine for the purpose of bleaching, to give a black glazing to pottery, and for freeing glass from the colour which it derives from the sesquioxide of iron. According to Berzelius, a few pounds of it added to each cask of water intended for sea-voyages, will preserve it sweet. In the laboratory, it is employed to obtain oxygen and chlorine, and to form the salts of manganese. Pharmaceutically it is used, in conjunction with sulphuric acid, for liberating chlorine from common salt, in the processes for preparing Aqua Chlorinii, *Dub.*, Calx Chlorinata, *Lond.*, and Liquor Sodæ Chlorinata, *Lond.* B.

MANNA. *U.S., Lond., Ed., Dub.*

Manna.

"The concrete juice of *Ornus Europæa*." *U.S.* "*Ornus Europæa. Succus concretus.*" *Lond.* "Sweet concrete exudation probably from several species of *Fraxinus* and *Ornus*." *Ed.*

Manne, Fr.; Manna, Germ., Ital.; Mana, Span.

Manna is not the product of one plant exclusively. Besides the *Ornus Europæa* indicated by the Pharmacopæias, it is said to be obtained also from several other species of *Ornus* and *Fraxinus*, among which the *O. rotundifolia*, *F. excelsior*, and *F. parviflora* have been particularly designated.

Burkhardt states that a species of manna, which exudes from the tamarisk of the North of Africa, is used by the Bedouin Arabs of the neighbourhood of Mount Sanai with their food. It is, however, chemically different from common manna, as, according to Mitscherlich, it contains no mannite, but consists wholly of mucilaginous sugar. Dr. Ehrenberg found the tree which produces it to be a variety of the *Tamarix Gallica*. The manna used in India is said to be the product of the *Hedysarum Alhagi* of Linn., the *Alhagi Maurorum* of De Candolle, a thorny shrub which grows abundantly in the deserts of Persia and Arabia. It is, however, much inferior to that obtained from the *Ornus* or *Fraxinus*. We are told by Dr. Richardson that a substance, exactly resembling manna, is procured by exudation from a species of *Eucalyptus* called the *E. mannifera*, growing in New South Wales. The substance known in France by the name of *Briançon Manna*, is an exudation upon the surface of the common European larch—*Larix Europæa* or *Pinus Larix*—and differs chemically from ordinary manna, in containing no mannite.

ORNUS. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Oleaceæ.

Gen. Ch. *Calyx* very small, four-cleft. *Corolla* divided to the base into linear segments. *Pericarp* a winged key not dehiscing. *Lindley.*

This genus was separated by Persoon from the *Fraxinus* of Linnæus, and is now admitted by the best botanists.

Ornus Europæa. Persoon, *Synops.* i. 9; *Lindley, Flor. Med.* 547.—*Fraxinus Ornus.* Willd. *Sp. Plant.* iv. 1104; *Woodv. Med. Bot.* p. 589. t. 209. The *flowering ash* is a tree of moderate height, usually from twenty to twenty-five feet, very branching, with opposite, petiolate, pinnate leaves, composed of three or four pairs of leaflets, and an odd one at the extremity. The leaflets are oval, acuminate, obtusely serrate, about an inch and a half in length, smooth, of a bright green colour, and stand on short footstalks. The flowers are white, and usually expand at the same time with the leaves. They grow in close panicles at the extremity of the young branches, and have a very short calyx with four teeth, and a corolla composed of four linear lanceolate petals.

Both this species of *Ornus* and the *O. rotundifolia*, are natives of Sicily, Calabria, and Apulia; and both contribute to supply the manna of commerce. During the hot months, the juice exudes spontaneously from the bark, and concretes upon its surface; but as the exudation is slow, it is customary to facilitate the process by making deep longitudinal incisions on one side of the trunk. In the following season these are repeated on the other side, and thus alternately for thirty or forty years, during which the trees are said to yield manna. Straws or clean chips are frequently placed so as to receive the juice, which concretes upon them. The manna varies much in its character, according to the mode of collection and nature of the season, and the period of the year in which the exudation takes place. That procured in Sicily is said to be the best. Three varieties are distinguishable in commerce.

1. The purest is that usually known by the name of *flake manna*, called also *manna cannulata*. It exudes spontaneously, or by incisions, during the hottest and driest weather in the months of July and August. It is in irregular, unequal pieces, often several inches long, somewhat similar in appearance to stalactites, rough, light, porous, brittle, of a whitish or yellowish-white colour, and frequently concave on the surface by which they were attached to the trunk, and which is often soiled by impurities, sometimes by adherent fragments of the bark. When broken, these pieces exhibit a crystalline or granular structure. This variety is sometimes in small fragments, generally less than an inch in length.

2. *Common manna*—*manne en sorte* of French pharmacy—is next in quality, and is collected in September and the beginning of October, when the heat of the weather has begun to moderate. The juice does not now concrete so readily, and a portion, falling on the ground at the root of the tree, becomes more or less mixed with impurities, and forms imperfectly solid masses, which require to be further dried in the sun. The common manna consists of whitish or yellowish fragments similar to the pieces of flake manna, but much smaller, mixed with a soft, viscid, uncrystallized brownish matter, identical with that which constitutes the following variety.

3. *Fat manna* is collected in the latter part of October and November, when the weather is cooler and rains more common. The juice is now still less disposed to concrete, and flowing down the trunk is received in a small excavation at its base. As found in commerce it is in the form of a soft, viscous mass, containing few crystalline fragments, of a brown or yellowish-brown colour, and full of impurities.

Manna may be found in the shops of every grade, from the most impure of the third variety to the purest of the first; but the worst kind is not often imported into this country.

Attempts have sometimes been made to counterfeit it; but the facility of detection renders frauds of this kind unprofitable, and they are not often practised. Baumé describes a method in which common manna is purified so as to resemble flake manna. It consists in dissolving common manna in a little water, allowing the liquid to settle, decanting it in order to separate the impurities, then inspissating it so that it will congeal on cooling, and immersing threads in the inspissated liquid several times successively in the manner practised by the candle-makers. It may be still further purified by the use of animal charcoal. Thus prepared it contains less mannite than flake manna, and less of the nauseous principle; but is said not to operate less effectively as a laxative. (*See Am. Journ. of Pharm.* ix. 45.)

Properties. Manna has a slight, peculiar odour, and a sweet taste, which in the impure kinds is also very nauseous, but in the finest flake manna, scarcely so much so as to be disagreeable. It melts with heat, and takes fire, burning with a blue flame. When pure it is soluble in three parts of cold, and in its own weight of boiling water. From a boiling saturated aqueous solution, it separates in partially crystalline masses. Alcohol also dissolves it, and, if saturated by means of heat, deposits upon cooling a large proportion of the manna in a beautifully crystalline form. Analyzed by Fourcroy and Vauquelin, manna was found to consist of, 1. a peculiar crystallizable saccharine principle, called *mannite*, which constitutes seventy-five per cent.; 2. true sugar; 3. a yellow nauseous matter, upon which the purgative property is thought chiefly to depend; and 4. a small quantity of mucilage. It is owing to the presence of true sugar that manna is capable of fermenting. *Mannite* is white, inodorous, crystallizable in semi-transparent needles, of a sweetish taste, soluble in five parts of cold water, scarcely soluble in cold alcohol, but readily dissolved by that liquid when hot, and precipitated when it cools. Unlike sugar, it is incapable of undergoing the vinous fermentation. It may be obtained by boiling manna in alcohol, allowing the solution to cool, and redissolving the crystalline precipitate. Pure mannite is now deposited. This principle has been found in numerous vegetables. It is said to be gently laxative, in the dose of one or two ounces.

Manna, when long kept, acquires a deeper colour, softens, and ferments. That which is dryest resists this change the longest. It is said, when recently gathered, to be less purgative than it afterwards becomes.

Medical Properties and Uses. Manna is a gentle laxative, usually operating mildly, but in some cases producing flatulence and pain. Though peculiarly adapted to children and pregnant women, it may be given with advantage in ordinary cases of piles from constipation, unattended with dyspeptic symptoms. It is usually, however, prescribed with other purgatives, particularly senna, rhubarb, magnesia, and the neutral salts, the taste of which it conceals, while it adds to the purgative effect.

The dose for an adult is from one to two ounces; for children, from one to four drachms. It is usually given dissolved in water or some aromatic infusion; but the best flake manna may be conveniently administered in substance.

MARANTA. *Sex. Syst.* Monandria Monogynia.—*Nat. Ord.* Marantaceæ.

Gen. Ch. *Anther* attached to the petal-like filament. *Style* petal-shaped. *Stigma* three-sided. *Flowers* panicle. *Loudon's Encyc.*

Maranta arundinacea. Willd. *Sp. Plant.* i. 13; *Loudon's Encyc. of Plants*, p. 2. The root of this plant is perennial, tuberous, fleshy, horizontal, nearly cylindrical, scaly, from six inches to a foot or more in length, and furnished with numerous long white fibres. The stems, of which several rise from the same root, are annual, slender, branched, jointed, leafy, and about three feet in height. The leaves are ovate lanceolate, about four inches long, alternate, and supported solitarily at the joints of the stem upon long, sheathing footstalks. The flowers are in a long, loose, spreading, terminal panicle, at each ramification of which is a solitary linear bracte. The calyx consists of three small lanceolate leaves. The corolla is white and monopetalous, with a tube longer than the calyx, and a double border, of which the three outermost segments are smallest, and the two inner obovate, and slightly emarginate.

The arrow-root plant is a native of the West Indies, where it is largely cultivated. It has been cultivated also in our Southern States, but not very extensively, as we still derive our supplies of its product from abroad. The plant is easily propagated by cuttings of the root. In the West Indies, the fecula, so well known by the name of arrow-root, is prepared in the following manner. The roots are dug up when a year old, washed, and then beat into a pulp, which is thrown into water, and agitated so as to separate the amylaceous from the fibrous portion. The fibres are removed by the hand, and the starch remains suspended in the water, to which it gives a milky colour. This milky fluid is strained through coarse linen, and allowed to stand that the fecula may subside, which is then washed with a fresh portion of water, and afterwards dried in the sun. We obtain the official arrow-root chiefly, if not exclusively, from the West Indies, and that from the Bermudas is most highly esteemed.

But other plants contribute to furnish the arrow-root of commerce. Lind-

ley states that it is procured in the West Indies from the *Maranta Allouya* and *M. nobilis*, besides the *M. arundinacea*. Under the name of *M. Indica*, Tussac describes a distinct species which he says was originally brought from the East Indies, and is now cultivated in Jamaica. This, however, is generally considered as a mere variety of the *M. arundinacea*, from which it differs chiefly in having leaves more elongated at the point, and smooth on both sides. Very fine arrow-root is obtained in the East Indies from the root of the *Curcuma angustifolia* of Roxburgh, which is abundantly cultivated in Travancore. Parcels occasionally reach this country, but from the length of the voyage are apt to be musty. The East India arrow-root is lighter than ours, and does not so quickly make a jelly. Ainslie states that the *M. arundinacea* has been introduced from the West Indies into Ceylon, where good arrow-root is prepared from it. A fecula closely resembling that of the Maranta, is said by Guibourt to be prepared in the West Indies from the root of the cassava plant, *Jatropha Manihot*; and it is not improbable that a variety of arrow-root brought to this country from Brazil has a similar origin. In fact, it often contains small lumps, as large as a pin's head, identical with tapioca, which is a product of the *J. Manihot*. A variety of arrow-root has been imported from the Sandwich Islands. It was supposed to be identical with that said to be procured from the root of the *Tacca pinnatifida*, which grows abundantly in Tahiti and other islands of the South Pacific; but Mr. Nuttall, during his visit to the Sandwich Islands, found that it was the product of another species of *Tacca*, which he has described under the name of *Tacca oceanica*. (See *Am. Journ. of Pharm.* ix. 305.) The fecula called *tous-les-mois* has already been noticed. (See *Canna*, page 159.) Arrow-root is occasionally brought into the market from Florida, prepared in the neighbourhood of St. Augustine from the root of the *Zamia integrifolia*, by a process similar to that employed in the preparation of the fecula of the Maranta. (See a paper by Dr. Joseph Carson in the *Am. Journ. of Pharm.* xiv. 22.)

Attempts have been made to substitute finely prepared potato starch for arrow-root; and there is no doubt that, medically considered, it is quite equal; but patients complain of an unpleasant taste of the potato which it is apt to retain.

Arrow-root is in the form of a light white powder, or of small pulverulent masses, without smell or taste. It has a firm feel when pressed between the fingers, and produces a faint crackling sound when rubbed. It is a pure starch, identical in chemical properties with that of wheat and the potato. It is very apt to be musty, and should then be rejected. It is said to be sometimes adulterated with common starch, and with that of the potato. There is no certain mode of detecting these, except by the microscope. (See *Amylum*.) The odour and taste are the best criteria of its purity. It should be perfectly free from smell and unpleasant flavour. Mr. Procter has rendered musty arrow-root quite sweet and fit for use by washing it thoroughly with two successive portions of cold water, and then drying it upon frames of muslin in a warm place. (*Am. Journ. of Pharm.* xiii. 188.)

As the microscope affords the best means of distinguishing the different varieties of fecula sold as arrow-root, or used for its adulteration, it is proper to indicate the form of their granules as exhibited by this instrument. Those of the proper officinal or *Maranta arrow-root* are rarely oblong, somewhat ovate-oblong, or irregularly convex, with very fine rings, a circular hilum which cracks in a linear or stellate manner, and small mammillary processes occasionally projecting from them. (*Pereira*.) The largest are the 750th of an inch, but many not more than the 2000th of an inch long;

and their breadth is generally two-thirds of their length. (*Christison*.) The granules of the *East India arrow-root* are, according to *Pereira*, of unequal size, ovate or oblong-ovate, flattened, and often furnished with a very short neck or nipple-like projection. The rings are numerous, close, and very fine; and the hilum, which is situated at the narrow extremity, is circular, small, and indistinct. The microscopic appearance of the *Tapioca fecula* will be described under the head of *Tapioca*, to which the reader is referred. The *Tacca fecula* from the South Sea Islands, examined by *Pereira*, consisted of circular, muller-shaped, or polyhedral granules, with few and not very distinct rings, and a small, circular hilum, which cracked in a linear or stellate manner. The *Florida arrow-root* was found by *Dr. Carson* to consist of granules forming the half, the third, or the quarter of a solid sphere. The *potato starch* granules are of various shape and size, but generally ovate or elliptical, and from the 7000th to the 300th of an inch in length, the largest being inferior in size only to the largest of the *canna starch* or *tous-les-mois*. (See *Canna*.) They are strongly marked with concentric rings, and have a circular hilum, from which usually proceed the cracks observable in some of the larger grains. (*Pereira*.)

Medical Properties and Uses. Arrow-root is nutritious and demulcent, affording a light, very mild, and easily digested article of diet, well adapted for the sick and convalescent, and peculiarly suited, from its demulcent properties, to bowel complaints and diseases of the urinary passages. It is much used as food for infants after weaning, or when the mother's milk is insufficient. It is prepared by dissolving it in hot water, with which it forms a pearly gelatinous solution, and, if in sufficient quantity, a jelly-like mass on cooling. A tablespoonful will communicate sufficient consistence to a pint of water. It should first be formed into a paste with a small quantity of cold water, and the boiling water then gradually added with brisk agitation. The preparation may be rendered more palatable by the addition of lemon-juice and sugar, or in low forms of disease by that of wine and spices, if the latter are not contra-indicated. For children the arrow-root is usually prepared with milk.

Marble.

“White granular carbonate of lime.” *U. S.* “Carbonas calcis (*dura*).” *Lond.* “Massive crystalline carbonate of lime.” *Ed.*

Off. Syn. CALCIS CARBONAS. MARMOR ALBUM. *Dub.*

White marble; Marbre, *Fr.*; Marmor, *Germ.*; Marmo, *Ital.*; Marmol, *Span.*

Marble is used for obtaining carbonic acid, and for making several official preparations. For the former purpose, common marble is sufficiently pure; but for the latter, the purer varieties must be selected.

The official marble is a white granular substance, having a specific gravity varying from 2.7 to 2.8. It is brittle, pulverizable, and insoluble in water. It is wholly dissolved in dilute muriatic acid with effervescence. If magnesia be present, the neutral muriatic solution will be precipitated by ammonia; and if baryta or strontia be an impurity, a similar effect will be produced by a solution of sulphate of lime. When marble is exposed to a full red heat, it loses about 44 per cent. of carbonic acid, and is converted into lime. (See *Calx*.) In composition it agrees with chalk.

The purest kind of marble is that of *Carrara*, sometimes called *statuary*

marble; but it is not necessary that this kind should be obtained for pharmaceutical operations. Marble, sufficiently pure for these purposes, is found in various parts of the United States. It is necessary, however, to reject the *dolomitic marbles*, which contain a considerable proportion of magnesia.

Marble is used by the Edinburgh College, merely to get rid of excess of acid by saturating it, in the processes for preparing muriate of morphia, and the sulphates of potassa and soda.

Marrubium vulgare. Willd. *Sp. Plant.* iii. 111; Woodv. *Med. Bot.* p. 332. t. 118. The white horehound has a perennial fibrous root, and numerous annual stems, which are quadrangular, erect, very downy, and from twelve to eighteen inches high. The leaves are roundish ovate, dentate or deeply serrate, wrinkled, veined, hoary on the under surface, and supported in pairs upon strong footstalks. The flowers are white, and disposed in crowded axillary whorls. The calyx is tubular, and divided at the margin into ten narrow segments which are hooked at the end. The corolla is also tubular, with a labiate margin, of which the upper lip is bifid, the under reflected and three-cleft, with the middle segment broad and slightly scolloped. The seeds are four, and lie in the bottom of the calyx.

This plant is a native of Europe, but has been naturalized in this country, where it grows on the roadsides, and flowers in July and August. It is also cultivated in our gardens.

The herb has a strong rather agreeable odour, which is diminished by drying, and is lost by keeping. Its taste is bitter and durable. The bitterness is extracted by water and alcohol. It contains a volatile oil, bitter extractive, resin, tannin, and lignin.

Medical Properties and Uses. Horehound is tonic, in large doses laxative, and may be so given as to increase the secretion from the skin, and occasionally from the kidneys. It was formerly considered a valuable deobstruent, and recommended in chronic hepatitis, jaundice, menstrual obstructions, phthisis, and various cachectic affections. By its gently tonic powers it may undoubtedly have proved advantageous in some of these complaints; but it exerts no specific influence over any; and has now passed almost entirely from the hands of physicians into domestic use. It is employed chiefly in catarrh, and other chronic affections of the lungs attended with cough and copious expectoration. The infusion made in the proportion of an ounce of the herb to a pint of boiling water, may be given in wineglassful doses. The dose of the powder is from thirty grains to a drachm. The medicine is also much used in the shape of syrup and candy. W.

PISTACIA. Sex. Syst. Diœcia Pentandria.—Nat. Ord. Anacardiaceæ.

Gen. Ch. MALE. Calyx five-cleft. Corolla none. FEMALE. Calyx three-cleft. Corolla none. Styles three. Drupe one-seeded. Willd.

Pistacia Lentiscus. Willd. *Sp. Plant.* iv. 753; Woodv. *Med. Bot.* p. 26. t. 11. The *lentisk* is a shrub or small tree, seldom rising more than twelve feet in height, much branched towards the top, and furnished with petiolate, abruptly pinnate leaves. The leaflets are from eight to twelve in number, usually alternate, with the exception of the two upper which are opposite. They are ovate lanceolate, entire, obtuse, often mucronate, and sessile upon the common footstalk, which is winged, or furnished with a narrow foliaceous expansion on each side. The flowers are diœcious, and very small. The male are in an axillary ament; the female are arranged alternately upon a common peduncle, which is also axillary.

This tree is a native of the countries which border upon the Mediterranean; but does not yield mastic in all places. The island of Scio in the Grecian Archipelago is the place whence the drug is chiefly obtained. Incisions are made in the trunk and principal branches, from which the juice slowly exudes, and either hardens in tears upon the bark, or drops on the ground, where it is sometimes received upon cloths, sometimes upon the bare earth, and concretes in irregular masses. The tears are most esteemed. They are of various sizes, oval or roundish, often compressed, smooth, semi-transparent, of a pale yellow colour, of a shining fracture, friable, and usually covered with a whitish powder, occasioned by their friction against each other. The masses are composed of yellowish tears agglutinated together, with others of a darker colour and less translucent, and often fragments of wood, bark, or earthy matter intermingled.

Mastic is nearly inodorous, unless rubbed or heated, when it becomes fragrant. Its taste is weak but agreeably terebinthinate, and, after long chewing, very slightly acrid. It is at first friable under the teeth, but soon becomes soft and ductile, and acquires a white opaque appearance. Its sp. gr. is 1.074. It is fusible and inflammable by heat. Alcohol dissolves about four-fifths of it, leaving a viscid substance which becomes brittle when dried, and for which the name of *masticin* has been proposed. This substance, though not dissolved by alcohol, softens and swells up in it, as gluten does in water. According to Berzelius, it enjoys the same general properties as copal, and should be considered as a variety of resin. Mastic is wholly soluble in ether and in oil of turpentine, scarcely soluble in the fixed oils, and insoluble in water. It consists chiefly of resin, with *masticin*, and a minute proportion of volatile oil, which can scarcely be said to have been obtained in a separate state, though it imparts flavour to alcohol and water distilled from the mastic, especially when this has been previously triturated with an equal weight of carbonate of potassa.

Medical Properties and Uses. Mastic was formerly thought to possess properties analogous to those of the turpentine, and was used in debility of

the stomach, hæmoptysis from ulceration, leucorrhœa, chronic diarrhœa, &c.; but its virtues were overrated; and it is at present scarcely ever given internally. It is sometimes employed to fill the cavities of carious teeth, for which purpose it is well fitted by its softness. Great quantities of it are consumed in Turkey, where it is habitually chewed by the women, under the impression that it sweetens the breath, and preserves the gums and teeth. Dissolved in alcohol or oil of turpentine, it serves for the formation of a brilliant varnish.

The following mode of applying it to carious teeth is highly recommended. Dissolve four parts of mastich in one part of sulphuric ether, in a bottle well stopped. With the solution thus formed, which is of a yellow colour and oily consistence, saturate a small piece of cotton of the size of the carious cavity, and having well cleansed and dried the cavity, introduce the cotton, without painful pressure, so as to fill it exactly. The ether is soon evaporated, and the resin, remaining soft and adhesive, attaches itself to the diseased surface of the tooth, which it protects from the action of the air, and of the food taken into the mouth. MATRICARIA. U.S. Secondary.

German Chamomile.

“The flowers of *Matricaria Chamomilla*.” U. S.

MATRICARIA. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ-Senecionideæ, *De Cand.* Asteraceæ, *Lindley*.

Gen. Ch. Calyx flat, imbricate, with scales having scarious margins. Receptacle naked, terete. Pappus none.

Matricaria Chamomilla. Linn. *Sp.* 1256. This is an annual plant, with a branching stem a foot or two in height, bearing alternate leaves about two inches long, the lower ones tripinnate, the upper bipinnate or simply pinnate, and all of them very green, and nearly or quite smooth. The leaflets are linear and very small. The flowers appear singly at the ends of the stem and branches. They are about three-quarters of an inch in diameter, with the ray spreading. The scales of the calyx are obtuse, green in the middle, and whitish, membranous, and translucent at the margin. The ray florets are white, at first spreading, and ultimately reflected. The disk is of a deep yellow colour, at first flat, but in the end convex, and even somewhat conical.

The plant is a native of Europe, and has been occasionally cultivated in our gardens. All parts of it are active; but the flowers only are officinal with us. These shrink very much in drying, so that they are scarcely half as large as in their recent state. Those found in our shops are imported from Germany.

The dried flowers of the *Matricaria* are considerably smaller than common chamomile, and exhibit a larger proportion of the disk florets compared with those of the ray. They have a strong, peculiar, rather unpleasant odour, and a disagreeable bitter taste. Their active constituents are volatile oil and bitter extractive, which are readily extracted by water and alcohol. The oil, which is obtained by distillation with water, is thick, somewhat tenacious, of a dark-blue colour becoming brown by age, and almost opaque in mass.

Medical Properties and Uses. *Matricaria* is a mild tonic, very similar

to chamomile in medical properties, and, like it, capable in large doses of producing an emetic effect. It is esteemed also in Europe antispasmodic and anthelmintic. It is much employed in Germany; but in this country scarcely at all unless by some German practitioners. It may be given for the same purposes and in the same manner as chamomile. W.

MEL. *U.S., Lond., Ed., Dub.*

Honey.

"A liquid prepared from flowers by *Apis mellifica*." *U.S.* "*Apis mellifica. Humor è floribus decerptus, et ab ape paratus.*" *Lond.* "Saccharine secretion of *Apis mellifica*." *Ed.*

Miel, *Fr.*; Honig, *Germ.*; Miele, *Ital.*; Miel, *Span.*

Naturalists have not yet determined whether honey is a secretion of the bee, *Apis mellifica*, or whether it exists already formed in plants. It is certain that the nectaries of flowers contain a saccharine matter, which is extracted by the insect, and the fact is well known that the flavour and character of honey are very much affected by the nature of the plants which predominate in the vicinity of the hive; so much so, that when these plants are poisonous, the fluid sometimes partakes of their noxious qualities. Still, it probably undergoes some change in the organs of the bee; as the saccharine matter of the nectaries, so far as it has been possible to examine it, wants some of the characteristic properties of honey.

The finest honey is that which is allowed to drain from the comb. If obtained from hives that have never swarmed, it is called *virgin honey*. An inferior kind is procured by exposing the comb to pressure, and if heat be employed previous to expression, the product is still more impure.

Much honey is collected in different parts of the United States; but that with which the shops of cities on the seaboard are supplied, is derived chiefly from Cuba.

In the recent state honey is fluid; but, on being kept, it forms a crystalline deposit, and is ultimately converted into a soft granular mass. In the shops it is found of every consistence, from that of a viscid liquid like thin syrup or oil, to that of lard or soft suet. Its colour is sometimes white, but usually yellowish, and occasionally of a brown or reddish tinge. It has a peculiar agreeable odour, varying somewhat with the flowers from which it was collected, and a very sweet feebly aromatic taste, which is followed by a slight prickling or sense of acrimony in the fauces. Its specific gravity is about 1.333. (*Duncan*.) Cold water dissolves it readily, alcohol with less facility. It contains crystallizable sugar analogous to that of grapes, uncrystallizable sugar, an aromatic principle, an acid, wax, and, according to Guibourt, a little mannite. The crystalline sugar may be obtained by treating granular honey with a small quantity of alcohol, which when expressed takes along with it the other ingredients, leaving the crystals nearly untouched. The same end may be attained by melting the honey, saturating its acid with carbonate of lime, filtering the liquid, then setting it aside to crystallize, and washing the crystals with alcohol. Inferior honey usually contains a larger proportion of uncrystallizable sugar and vegetable acid. Diluted with water, honey undergoes the vinous fermentation; and treated with nitric acid, is converted into oxalic acid.

In warm weather, honey, if not very pure, sometimes ferments, acquiring a pungent taste, and a deeper colour. Starch is said to be occasionally added to the inferior kinds to give them a white appearance. The adulteration

may be detected by dilution with water, which dissolves the honey and leaves the starch at the bottom of the vessel. The nature of the deposit may be tested by the tincture of iodine. Water is said to be sometimes added to honey to increase its bulk. Its presence may be suspected from the greater thinness of the liquid, and its want of disposition to crystallize.

Medical Properties and Uses. Honey possesses the same medical properties with sugar, but is more disposed to run off by the bowels, and to occasion griping pain. Though largely consumed as an article of food, it is seldom employed medicinally, except as the vehicle of more active substances. Its taste and demulcent qualities render it a useful addition to gargles, and it is sometimes employed as an application to foul ulcers, and in the form of enema.

Melisse, *Fr.*; Garten-Melisse, *Germ.*; Melissa, *Ital.*; Torongil, *Span.*

MELISSA. *Sex. Syst.* Didynamia Gymnospermia.—*Nat. Ord.* Lamiaceæ or Labiataæ.

Gen. Ch. Calyx dry, nearly flat above; with the upper lip sub-fastigiæte. Corolla, upper lip somewhat arched, bifid; lower lip with the middle lobe cordate. *Willd.*

Melissa officinalis. *Willd. Sp. Plant.* iii. 146; *Woodv. Med. Bot.* p. 334. t. 119. Balm has a perennial root, which sends up annually several erect, quadrangular stems, usually branched towards the base, and a foot or two in height. The leaves are opposite, ovate or cordate, deeply serrate, pubescent; the lower on long footstalks, the uppermost nearly sessile. The flowers are white or yellowish, upon short peduncles, and in axillary whorls, surrounding only half the stem. The calyx is tubular, pentangular, and bilabiate, with the upper lip tridentate and flattened, the lower cut into two pointed teeth. The corolla is also tubular and bilabiate, the upper lip less convex and notched, the lower three-cleft.

The plant is a native of the South of Europe. It has been introduced into this country, where it is cultivated in gardens, and grows wild along the fences of our roads and lanes. For medical use the herb should be cut before the appearance of the flowers, which begin to expand in July.

In the fresh state, it has a fragrant odour very similar to that of lemons; but is nearly inodorous when dried. The taste is somewhat austere and slightly aromatic. The herb contains a minute proportion of a yellowish or reddish-yellow essential oil, which has its peculiar flavour in a very high degree. It contains also tannin, bitter extractive, and gum.

Medical Properties and Uses. Balm scarcely produces any remedial operation upon the system. The quantity of oil which it contains is not more than sufficient to communicate a pleasant flavour to the infusion, which forms an excellent drink in febrile complaints, and when taken warm tends to promote the operation of diaphoretic medicines. MENTHA PIPERITA. U.S., Lond., Ed., Dub.

Peppermint.

"The herb of *Mentha piperita*." U.S., Ed. "*Mentha piperita*." Lond. *Menthe poivrée*, Fr.; *Pfeffermünze*, Germ.; *Mentha piperita*, Ital.; *Pimenta piperita*, Span.

MENTHA. Sex. Syst. Didynamia Gymnospermia.—Nat. Ord. Lamiaceæ or Labiata.

Gen. Ch. Corolla nearly equal, four-cleft; the broader segment emarginate. Stamens upright, distant. Willd.

Mentha piperita. Willd. Sp. Plant. iii. 79; Woodv. Med. Bot. p. 336. t. 120. Peppermint is a perennial herbaceous plant, with a creeping root, and quadrangular, channeled, purplish, somewhat hairy stems, which are branched towards the top, and about two feet in height. The leaves are opposite, petiolate, ovate, serrate, pointed, smoother on the upper than the under surface, and of a dark green colour which is paler beneath. The flowers are small, purple, and disposed in terminal obtuse spikes, which are interrupted below. The calyx is tubular, furrowed, and five-toothed; the corolla is also tubular, with its border divided into four segments, of which the uppermost is broadest, and notched at its apex. The anthers are concealed within the tube of the corolla; the style projects beyond it, and terminates in a bifid stigma. The four-cleft germ is converted into four seeds, which are lodged in the calyx.

This species of mint is a native of Great Britain, whence it has been conveyed to the continent of Europe and to this country. In some parts of the United States, especially in New England, the western part of New York, Ohio, and New Jersey, it is largely cultivated for the sake of its volatile oil. We occasionally find it growing wild along the fences of our villages. The cultivators of this herb have observed that, in order to maintain its flavour in perfection, it is necessary to transplant the roots every three years. It should be cut for medical use in dry weather, about the period of the expansion of the flowers. These appear in August.

The herb, both in the recent and dried state, has a peculiar, penetrating, grateful odour. The taste is aromatic, warm, pungent, glowing, camphorous, bitterish, and attended with a sensation of coolness when air is admitted into the mouth. These properties depend on a volatile oil, which abounds in the herb, and may be separated by distillation with water. (See *Oleum Menthæ Piperitæ*.) The virtues of the herb are imparted to water, and more readily to alcohol.

Medical Properties and Uses. Peppermint is a very grateful aromatic stimulant, much used for all the purposes to which medicines of this class are applied. To allay nausea, to relieve spasmodic pains of the stomach and bowels, to expel flatus, to cover the taste or qualify the nauseating or griping effects of other medicines, are among the most common of these purposes. The fresh herb, bruised and applied over the epigastrium, often allays sick stomach, and is especially useful in the cholera of children. The medicine may be given in infusion; but the volatile oil, either alone, or in some state of preparation, is almost always preferred.

Menthe a epi, Fr.; Grune Münze, Germ.; Menta Romana, Ital.; Yerba buena puntia-guda, Span.

MENTHA. See MENTHA PIPERITA.

Mentha viridis. Willd. *Sp. Plant.* iii. 76; Woodv. *Med. Bot.* p. 338.
t. 121. Spearmint, sometimes called simply *mint*, differs from the *M. piperita* chiefly in having sessile, or nearly sessile, lanceolate, naked leaves; elongated, interrupted, paniced spikes; setaceous bractes; and stamens longer than the tube of the corolla. Like the two preceding species, it is a native of Europe. In this country it is cultivated in gardens for domestic use, and in some places more largely for the sake of its oil. It also grows wild in low grounds in parts of the country which have been long settled. Its flowering season is August. According to Thomson, it should be cut in very dry weather, and, if intended for medical use, just as the flowers appear; if for obtaining the oil, after they have expanded.

The odour of spearmint is strong and aromatic, the taste warm and slightly bitter, less pungent than that of peppermint, but considered by some as more agreeable. These properties are retained for some time by the dried plant. They depend on a volatile oil which rises on distillation with water, and is imparted to alcohol and water by maceration. (See *Oleum Menthæ Viridis.*)

Medical Properties. The virtues and applications of this plant are the same with those of peppermint.

Off. Syn. MENYANTHES TRIFOLIATA. *Folia. Dub.*

Menyanthe, Tréfle d'eau, *Fr.*; Bitterklee, *Germ.*; Trifoglio pulustre, *Ital.*; Trifolio palustre, *Span.*

MENYANTHES. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Gentianaceæ.

Gen. Ch. Corolla hirsute. Stigma bifid. Capsule one-celled. *Willd.*

Menyanthes trifoliata, Willd. *Sp. Plant.* i. 811; Bigelow, *Am. Med. Bot.* iii. 55. The buckbean or marsh trefoil has a perennial, long, round, jointed, horizontal, branching, dark-coloured root or rhizoma, about as thick as the finger, and sending out numerous fibres from its under surface. The leaves are ternate, and stand upon long stalks, which proceed from the end of the root, and are furnished at their base with sheathing stipules. The leaflets are obovate, obtuse, entire or bluntly denticulate, very smooth, beautifully green on their upper surface and paler beneath. The scape or flower stalk is erect, round, smooth, from six to twelve inches high, longer than the leaves, and terminated by a conical raceme of whitish somewhat rose-coloured flowers. The calyx is five parted; the corolla funnel-shaped, with a short tube, and a five-cleft, revolute border, covered on the upper side with numerous long, fleshy fibres. The anthers are red and sagittate; the germ ovate, supporting a slender style longer than the stamens, and terminating in a bifid stigma. The fruit is an ovate, two-valved, one-celled capsule, containing numerous seeds.

This beautiful plant is a native both of Europe and North America, growing in boggy and marshy places which are always moist, and occasionally overflowed with water. It prevails, in the United States, from the northern boundary to Virginia. In this country the flowers appear in May, in England not till June or July. All parts of it are medicinal. The leaves are directed by the Edinburgh and Dublin Colleges, the whole plant by the London College.

The taste of buckbean is intensely bitter and somewhat nauseous, the odour of the leaves faint and disagreeable. The virtues of the plant depend on a bitter extractive, which is dissolved by water and alcohol.

Medical Properties and Uses. With the ordinary properties of the bitter tonics, *Menyanthes* unites a cathartic power, and in large doses is apt to vomit. It was formerly held in high estimation in Europe as a remedy in numerous complaints, among which were intermittents, rheumatism, scrofula, scurvy, dropsy, jaundice, and various cachectic and cutaneous affections. In most of these complaints it was administered under a vague impression of its alterative powers. It is scarcely ever employed in this country; but as it is a native plant, capable of useful application in cases where a combined tonic and purgative effect is demanded, it is desirable that our country practitioners should be aware of its properties, and prepared to take advantage of them should occasion offer.

The dose of the powdered leaves or root as a tonic is from twenty to thirty grains; of an infusion, prepared with half an ounce to a pint of boiling water, from one to two fluidounces; and of the extract ten or fifteen grains, to be repeated three or four times a day. A drachm of the powder, or a gill of the strong decoction generally purges, and often occasions vomiting.

MEZEREUM. U.S., Lond.

Mezereon.

"The bark of *Daphne Mezereum* and *Daphne Gnidium*." U. S. "*Daphne Mezereum. Radicis Cortex.*" Lond.

Off. Syn. MEZEREON. Root-bark of *Daphne Mezereon*. Ed.; MEZEREON. DAPHNE MEZEREUM. Cortex. Dub.

Bois gentil, Fr.; Kellerbals, Germ.; Mezereo, Ital.; Mecereon, Span.

DAPHNE. Sex. Syst. Octandria Monogynia.—Nat. Ord. Thymelacæ.

Gen. Ch. Calyx none. Corolla four-cleft, withering, enclosing the stamens. Drupe one-seeded. Willd.

All the species of *Daphne* are possessed of active properties; but two only are officinal—the *D. Mezereum* and *D. Gnidium*—the former of which is recognised in the British Pharmacopœias, the latter in the French Codex, and both in the Pharmacopœia of the United States.

1. *Daphne Mezereum*. Willd. *Sp. Plant.* ii. 415; Woodv. *Med. Bot.* p. 717. t. 245. This is a very hardy shrub, three or four feet high, with a branching stem, and a smooth dark-gray bark, which is very easily separable from the wood. The leaves spring from the ends of the branches, are deciduous, sessile, obovate lanceolate, entire, smooth, of a pale green colour, somewhat glaucous beneath, and about two inches long. They are preceded by the flowers, which appear very early in spring, and sometimes bloom even amidst the snow. These are of a pale rose colour, highly fragrant, and disposed in clusters, each consisting of two or three flowers, forming together a kind of spike at the upper part of the stem and branches. At the base of each cluster are deciduous floral leaves. The fruit is oval, shining, fleshy, of a bright red colour, and contains a single round seed. Another variety produces white flowers and yellow fruit.

This species of *Daphne* is a native of Great Britain and the neighbouring continent, in the northern parts of which it is particularly abundant. It is cultivated in Europe both for medicinal purposes, and as an ornamental plant, and is occasionally found in our own gardens. It flowers in February, March, or April, according to the greater or less mildness of the climate.

2. *D. Gnidium*. Willd. *Sp. Plant.* ii. 420. In this species, called *garou* or *sain-bois* by the French, the leaves are linear lanceolate, acute, entire, smooth, and irregularly but closely set upon the branches. The flowers are white, downy, odoriferous, and disposed in terminal paniced racemes. The fruit is globular, dry, at first green, but ultimately black. The *D. Gnidium* grows in dry uncultivated places in the South of Europe, and flowers in June. In France its bark is used indiscriminately with that of the former species.

Besides the officinal species above described, the *D. Laureola*, or *spurge laurel*, is said to furnish a portion of the mezereon of commerce; but its product is inferior in acrimony, and consequently in medicinal activity.

The bark of the root was the part directed by the former U. S. Pharmacopœia, as it now is by the British Colleges; and it is said to be exclusively employed in Great Britain. But the mezereon with which our markets are now supplied is evidently the bark of the stem; and the present Pharmacopœia, therefore, very properly directs the bark, without designating the part from which it must be taken. The British writers state that the bark of the root is the most active. The berries and leaves of the plant are also possessed of active properties; and the former have sometimes proved fatal

to children, who have been attracted by their beautiful colour. Pallas states that they are used as a purgative by the Russian peasants, and that thirty berries are required to produce this effect. The French authors observe that fifteen are sufficient to kill a Frenchman. Mezereon is brought to us chiefly from Germany.

Properties. Mezereon, as it comes to us, is usually in strips from two to four feet long and an inch or less in breadth, sometimes flat, sometimes partially rolled, and always folded in bundles, or wrapped in the shape of balls. It is covered externally with a grayish or reddish-brown wrinkled epidermis, very thin, and easily separable from the bark. Beneath the epidermis is a soft greenish tissue. The inner bark is tough, pliable, fibrous, striated, and of a whitish colour. When fresh it has a nauseous smell, but in the dry state is nearly inodorous. Its taste is at first sweetish, but afterwards highly acrid, and even corrosive. It yields its virtues to water by decoction. Vauquelin ascertained the presence of a peculiar principle in the bark of the *D. Alpina*. This has subsequently been discovered in other species, and has received the name of *daphnin*. Gmelin and Bär found it in the bark of the *D. Mezereum* associated with wax, an acrid resin, a yellow colouring matter, a reddish-brown extractive matter, an uncrystallizable and fermentable sugar, a gummy matter containing azote, ligneous fibre, malic acid, and several malates. *Daphnin* is in prismatic crystals grouped together, colourless, transparent, brilliant, slightly soluble in cold water, very soluble in boiling water, ether, and alcohol, without odour, and of a bitter, somewhat austere taste. It is obtained by treating the alcoholic extract of the bark with water, decanting the solution, precipitating with subacetate of lead, filtering, decomposing the excess of the subacetate by sulphuretted hydrogen, again filtering, evaporating to dryness, submitting the residue to the action of anhydrous alcohol, and evaporating the alcoholic solution to the point of crystallization. Though *daphnin* is probably not inactive, it is not the principle upon which the virtues of mezereon chiefly depend. Vauquelin thinks that in the recent plant these reside in an essential oil, which by time and exposure is changed into a resin, without losing its activity. The acrid resin observed by Gmelin and Bär, is probably the characteristic principle to which the bark owes its vesicating properties. It is obtained separate by boiling mezereon in alcohol, allowing the liquor to cool in order that it may deposit some wax which it has taken up, then distilling off the alcohol, and treating the residue with water, which leaves the resin. This is of a dark green, almost black colour, hard and brittle, and of an exceedingly acrid and permanent taste. In the isolated state, it is slightly soluble in water, and much more so when combined with the other principles of the bark. It appears, however, not to be a pure proximate principle, but rather a resinoid combination of an acrid vesicating fixed oil with another substance. The acrid principle of mezereon is partially given off by decoction with water, as proved by the irritating character of the vapour when inhaled; but none of it appears to escape when the bark is boiled with alcohol. (Squire, *Pharmaceutical Transactions*, i. 395.)

Medical Properties and Uses. The recent bark applied to the skin produces inflammation followed by vesication, and has been popularly used as an epispastic from time immemorial in some of the southern countries of Europe. The dried bark, though less active, is possessed of a similar property, and is occasionally employed in France by regular practitioners for the purpose of forming issues, in cases which do not admit of the use of Spanish flies. A small square piece of the bark, moistened with vinegar, is applied to the skin, and renewed twice a day till a blister is formed, and

occasionally afterwards in order to maintain the discharge. It is slow in its operation, generally requiring from twenty-four to forty-eight hours to vesicate. An irritant ointment is prepared from mezereon, which answers for application to blistered surfaces in order to maintain the discharge, and may be applied advantageously to obstinate, ill-conditioned, indolent ulcers. (See *Extractum Mezerei*.) The alcoholic extract of mezereon has also been employed to communicate irritant properties to issue peas.

Internally administered, mezereon is a stimulant capable of being directed to the skin or kidneys, and in large doses apt to excite purging, nausea, and vomiting. In overdoses it produces all the fatal effects of the acrid poisons, and a case of apparently severe narcotic effects has been recorded. (*Am. Journ. of Med. Sci.* xxi. 518.) It had at one time much reputation as a remedy in the secondary stages of the venereal disease, and still enters as an ingredient into the officinal compound decoction of sarsaparilla. It has also been thought to act favourably as an alterative in scrofulous affections, chronic rheumatism, and obstinate diseases of the skin. For this purpose it is usually administered in decoction. (See *Decoctum Mezerei*.) Dr. Withering cured a case of difficult swallowing, arising from paralysis, by directing the patient to chew frequently small pieces of the root. The affection, which had continued three years, was removed in a month. The dose of the bark in substance may be stated at ten grains, though it is seldom used in this way.

MONARDA. U. S.

Horsemint.

“The herb of *Monarda punctata*.” *U. S.*

MONARDA. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Lamiaceæ or Labiatae.

Gen. Ch. Calyx five-toothed, cylindric, striate. Corolla ringent, with a long cylindric tube; upper lip linear, nearly straight and entire, involving the filaments, lower lip reflected, broader, three-lobed, the middle lobe longer. *Nuttall.*

Monarda punctata. Willd. *Sp. Plant.* i. 126; *Am. Med. Recorder*, vol. ii. p. 496. This is an indigenous perennial or biennial plant, with herbaceous, obtusely angled, downy, whitish, branching stems, which rise one or two feet in height, and are furnished with oblong lanceolate, remotely serrate, smooth, punctate leaves. The flowers are yellow, spotted with red or brown, and are disposed in numerous whorls, provided with lanceolate, coloured bractes, longer than the whorl.

The horsemint grows in light gravelly or sandy soils from New Jersey to Louisiana, and flowers from June to September. The whole herb is employed. It has an aromatic smell, and a warm, pungent, bitterish taste; and abounds in a volatile oil, which may be separated by distillation with water.

Medical Properties and Uses. Horsemint is stimulant and carminative; but is seldom used in regular practice. In the state of infusion it is occasionally employed in families as a remedy for flatulent colic and sick stomach, and for other purposes to which the aromatic herbs are applied. It was introduced into the primary catalogue of the United States Pharmacopœia on account of the volatile oil which it affords. (See *Oleum Monardæ*.)

MORA. *Lond.**Mulberries.*

“*Morus nigra. Fructus.*” *Lond.*

Off. Syn. MORUS NIGRA. *Baccæ. Dub.*

Mures, Fr.; Schwarze Maulbeeren, Germ.; Morone, Ital.; Moras, Span.

MORUS. *Sex. Syst.* Monœcia Tetrandria.—*Nat. Ord.* Urticacæ.

Gen. Ch. MALE. *Calyx* four-parted. *Corolla* none. FEMALE. *Calyx* four-leaved. *Corolla* none. *Styles* two. *Calyx* berried. *Seed* one. *Willd.*

Morus nigra. *Willd. Sp. Plant.* iv. 36; *Woodv. Med. Bot.* p. 712. t. 243. This species of mulberry is distinguished by its cordate ovate, or lobed, unequally toothed, and scabrous leaves. It is a tree of middle size, supposed to have been brought originally from Persia into Italy, and thence spread over Europe and America. Its leaves afford food for the silk-worm; and the bark of the root, which is bitter and slightly acrid, has been employed as a vermifuge, especially in cases of the tape-worm, in the dose of two drachms infused in eight ounces of boiling water. But the fruit is the only portion directed by the Colleges.

This is oblong oval, of a dark reddish-purple almost black colour; and consists of numerous minute berries united together and attached to a common receptacle, each containing a single seed, the succulent envelope of which is formed by the calyx. It is inodorous, has a sweet, mucilaginous, acidulous taste, and abounds in a deep red juice. The sourish taste is owing, according to Hermbstadt, to the presence of tartaric acid.

Medical Properties and Uses. Mulberries are refreshing and laxative, and serve to prepare a grateful drink well adapted to febrile cases. A syrup is made from them, and used as a pleasant addition to gargles in inflammation of the throat. They are, however, more used as food than medicine. Our native mulberry, the fruit of the *M. rubra*, is quite equal to that of the imported species. The *M. alba*, originally from China, and now extensively cultivated as a source of food for the silk-worm, bears a white fruit, which is sweeter and less grateful than the others.

MOSCHUS. *Class* Mammalia. *Order* Pecora.

Gen. Ch. *Horns* none. *Fore teeth* eight in the lower jaw. *Tusks* one on each side in the upper jaw, projecting out of the mouth.

Moschus moschiferus. *Gmelin, Syst. Nat.* i. 172; *Rees's Cyclopædia.* This animal bears a close resemblance to the deer in shape and size. It is usually less than three feet in length, with haunches considerably more elevated than the shoulders. From its upper jaw two tusks project downwards out of the mouth, each about two inches long, curved backwards, and serving to extract the roots which are used as food by the animal. The ears are long

and narrow, and the tail very short. The fleece, which consists of strong, elastic, undulated hairs, varies in colour with the season, the age of the animal, and perhaps the place which it inhabits. The general colour is a deep iron gray. The individual hairs are whitish near the root, and fawn-coloured or blackish towards the tip. The musk is contained in an oval, hairy, projecting sac, found only in the male, situated between the umbilicus and the prepuce, from two to three inches long, and from one to two broad, communicating externally by a small hairy orifice at its anterior part, and marked posteriorly by a groove or furrow which corresponds with the opening of the prepuce. It is lined internally by a smooth membrane, which is thrown into a number of irregular folds forming incomplete partitions. In the vigorous adult animal, the sac sometimes contains six drachms of musk; but in the old seldom more than two drachms, and none in the young. The musk is secreted by the lining membrane, and in the living animal forms a consistent mass, which on the outside is compact and marked with the folds of the membrane, but is less firm towards the centre, where there is sometimes a vacant space. As first secreted it is probably in the liquid state, and a portion is occasionally forced out by the animal, to which it communicates its odour.

The musk deer inhabits the vast mountainous regions of central Asia, extending from India to Siberia, and from the country of the Turcomans to China. It is an active and timid animal, springing from rock to rock with surprising agility, and frequenting the snowy recesses, and most inaccessible crags of the mountains. Concealing itself during the day, it chooses the night for roaming in search of food; and, though said to be abundant in its native regions, is taken with difficulty. It is hunted for its hide, as well as for the musk. As soon as the animal is killed the sac is cut off, and dried with its contents; and in this state is sent into the market.

Musk varies in quality with the country inhabited by the animal. That procured from the mountains on the southern borders of Siberia, and brought into the market through Russia, is comparatively feeble. The best is imported from China, and is said to be the product of Tonquin. A variety intermediate between these is procured in the Himalaya Mountains and Thibet, and sent to Calcutta. We derive our chief supply from Canton, though, when the drug is scarce, portions are occasionally brought hither from Europe.

Two varieties are distinguished in the market, the Chinese and Russian. Both come in sacs, convex and hairy on one side, flat and destitute of hair on the other. The hairs are brownish-yellow, grayish, or whitish, stiff and short, and arranged concentrically around the orifice of the sac. The Chinese, which is the most highly valued, is in bags of a rounder shape, covered with brownish-yellow or reddish-brown hairs, and containing at most a drachm and a half of large grained, dark, strong-scented musk, having an ammoniacal odour. The Russian, which is contained in longer and larger bags, is small grained, of a clear yellowish-brown colour, of a weaker and more fetid odour, with less smell of ammonia.

Properties. Musk is in grains or lumps concreted together, soft and unctuous to the touch, and of a reddish-brown or ferruginous colour, resembling that of dried blood. Some hairs of the pod are generally mixed with it. The odour is strong, penetrating, and so powerfully diffusive, that one part of musk communicates its smell to more than 3000 parts of inodorous powder. (*Fée*). In some delicate individuals it produces headache and other disagreeable symptoms, and has even given rise to convulsions. The taste is bitter, disagreeable, and somewhat acrid. The colour of the powder is reddish-brown. Musk is inflammable, burning with a white flame, and leaving a light spongy charcoal. It yields, upon analysis, a great number

of proximate principles. Guibourt and Blondeau obtained water, ammonia, stearin, olein, cholesterin, an acid oil combined with ammonia, a volatile oil, muriate of ammonia, chlorides of potassium and calcium, an uncertain acid combined with ammonia potassa and lime, gelatin, albumen, fibrin, a highly carbonaceous matter soluble in water, a soluble calcareous salt with a combustible acid, carbonate and phosphate of lime, hair, and sand. (*Annal. de Chim. et de Phys.* ix. 327.) Besides these principles Geiger and Reinman found a peculiar bitter resin, osmazome, and a peculiar substance in part combined with ammonia. According to Guibourt and Blondeau, it contains 47 per cent. of volatile matter, thought by some to be chiefly ammonia, by others to be a compound of ammonia and volatile oil. Theimann obtained only from 10 to 15 per cent. But the quantity of volatile as well as of soluble matter varies exceedingly in different specimens. Thus Theimann found from 80 to 90 per cent. of matter soluble in water, Buchner only 54.5 per cent., and other chemists intermediate proportions. The proportion soluble in alcohol, as ascertained by different experimenters, varies from 25 to 62 per cent. Sulphuric ether is a good solvent. The watery infusion has a yellowish-brown colour, a bitterish taste, a strong smell of musk, and an acid reaction. The alcoholic tincture is transparent, and of a reddish-brown colour, with the peculiar odour of the medicine. The action of potassa upon musk is accompanied with the extrication of ammonia, and an increase of its peculiar odour. By the influence of heat and moisture long continued, ammonia is developed, which acts upon the fatty matter, producing a substance resembling adipocire, but, according to Guibourt, without diminishing the activity of the medicinal principles. The correctness, however, of this opinion, is perhaps questionable; and it is advisable to preserve the musk as much as possible unaltered. When kept in glass bottles, in a situation neither moist nor very dry, it remains for a great length of time without material change. The odour of musk is said to be very much diminished by mixing the medicine with syrup of almonds. (See *Med. Exam. N. S.* i. 541.)

Adulterations. The price of this medicine is so high, and the sources of supply so limited, as to offer strong temptations to adulteration; and it is said that little of the genuine, unmixed musk is to be found in the market. The sophistication commences with the Chinese, and is completed in Europe and this country. A common practice in the East is to open the sac, and to supply the place of the musk with an adulterated mixture. Sometimes the scrotum of the animal is filled with this mixture, and not unfrequently the sacs are manufactured out of the skin. Dried blood, from its resemblance in appearance to musk, is among the most common adulterations; but besides this, sand, lead, iron-filings, hair, animal membrane, tobacco, the dung of birds, wax, benzoin, storax, asphaltum, and other substances are introduced. These are mixed with a portion of musk, the powerful odour of which is diffused through the mass, and renders the discovery of the fraud sometimes difficult. It is said that the Chinese sometimes mix the musk of Tonquin with that of Siberia. The bags containing the drug should have the characters before described as belonging to the natural sac, and should present no evidence of having been opened. The slit is sometimes carefully sewed up, sometimes glued together. The former condition may be discovered by close inspection, the latter by immersion in hot water. Musk which burns with difficulty, which has a feeble odour, and a colour either pale or entirely black, which feels gritty to the finger, is very moist, or contains obvious impurities, should be rejected.

Medical Properties and Uses. Musk is stimulant and antispasmodic,

increasing the vigour of the circulation, and exalting the nervous energy, without producing, either as an immediate or secondary effect, any considerable derangement of the purely cerebral functions. Its medical uses are such as may be inferred from its general operation. In almost all spasmodic diseases, so far as mere relaxation of spasm is desirable, it is more or less efficacious; but peculiar advantages may be expected from it in those cases in which a prostrate condition of the system, attended with great nervous agitation, or irregular muscular action, calls for the united influence of a highly diffusible stimulant and powerful antispasmodic. Such are very low cases of typhous disease, accompanied with subsultus tendinum, tremors, and singultus. Such also are many instances of gout in the stomach, and other spasmodic affections of this organ. In very obstinate hiccough we have found it more effectual than any other remedy; and have seen great advantage from its use in those alarming and dangerous convulsions of infants which have their origin in spasm of the intestines. It is said to have done much good combined with opium, and administered in very large doses in tetanus. Epilepsy, hysteria, asthma, pertussis, palpitations, cholera, and colic, are among the numerous spasmodic affections in which circumstances may render the employment of musk desirable. The chief obstacles to its general use are its very high price, and the great uncertainty as regards the degree of its purity. Musk was unknown to the ancients. Aëtius was the first writer who noticed it as a medicine. It was introduced into Europe through the Arabians, from whose language its name was derived.

It may be given in the form of pill or emulsion. The medium dose is ten grains, to be repeated every two or three hours. In the cases of children it may be given with great advantage in the form of enema. The tincture, which is an officinal preparation, is sometimes prescribed.

MOXA. *Dub.*

Moxa.

“*Artemisia Chinensis et A. Indica. Folia.*” *Dub.*

The term *moxa* is employed to designate small masses of combustible matter, intended, by being burnt slowly in contact with the skin, to produce an eschar. They are of various forms, and made of different materials. The Chinese moxa is in small cones, from eight to twelve lines in height, and is prepared from the leaves of one or more species of *Artemisia*. The *A. Chinensis* and *A. Indica* are indicated by the Dublin College; but Lindley states that it is the *A. Moxa* of De Candolle which is employed. According to some authors, the part used is the down which covers the leaves and stems; but others, with greater probability, assert that it is a fine lanuginous substance prepared from the leaves by beating them in a mortar. A coarser and a finer product are obtained, the former of which is used for tinder, the latter worked up into moxa. A similar moxa has been made in France, by a similar process, from the leaves of the *A. vulgaris*, or common European mugwort.

Various substitutes have been proposed for the Chinese moxa, all composed of some light, porous, soft, inflammable substance, which burns slowly, and thus allows the heat to be regulated according to the effect desired. Linen rolled into a cylinder, cotton formed into the same shape and enclosed in a piece of linen, cords of cotton in small masses of various shapes, and

even common spunk made from the agaric of the oak, have been employed by different persons with the desired effect. But all these bodies are subject to the inconvenience of requiring to be constantly blown upon in order that their combustion may be sustained.

To remedy this defect, cotton impregnated with nitre has been recommended; and the moxa usually employed is prepared from that substance. It is important that the impregnation should be uniform, as otherwise different parts of the cylinder, burning with different degrees of rapidity, would produce unequal effects upon the skin. The following process is recommended. One pound of cotton is introduced into a vessel containing two ounces of nitre dissolved in half a gallon of water, and a moderate heat applied, till all the liquid is evaporated. The cotton when perfectly dry is formed into thin, narrow sheets, which are rolled round a central cord of linen, so as to form a cylinder from half an inch to an inch in diameter, and several inches long. This is enclosed in a covering of silk or linen sewed firmly around it; and when used may be cut by a razor into transverse slices a few lines in length. By leaving a hole in the centre of the cylinder, the combustion will be rendered more vigorous, and a deeper eschar produced.

The pith of the *Helianthus annuus*, or common sun-flower, has been proposed by M. Percy for the preparation of moxa, for which it is well adapted by the nitre which it contains, and which enables it to burn without insufflation. The stem, when perfectly mature, is cut into transverse sections about half an inch in thickness, which must be carefully dried, and kept in a perfectly dry place. They have this advantage, that, in consequence of the retention of the cortical portion, they may be held with impunity, while burning, between the fingers of the operator. They are, however, frequently defective in consequence of an insufficiency of nitre in the pith, or of the unequal inflammability of different parts of it.

M. Robinet has perfected the preparation of moxa, by combining the advantages of the two kinds last described. He rolls cotton round a small central cylinder of pith, and envelopes the whole in a piece of muslin, which is more or less firmly applied, according to the degree of compactness required. The cylinders thus made burn without assistance, uniformly, and with a rapidity proportionate to their firmness.

Dr. Jacobson, of Copenhagen, has proposed, as a substitute for the ordinary forms of moxa, small cylinders formed out of strips of paper imbued with a solution of chromate of potassa; and cotton, impregnated with the solution of chlorate of potassa instead of nitre, is said to answer an excellent purpose. (*Journ. de Pharm.* xix. 608.) Small cylinders made out of strips of coarse muslin imbued with the same solution are also employed.

Lime in the act of slaking has been employed by Dr. Osborne for the purposes of moxa. A portion of powdered quicklime, half an inch in thickness, and of suitable lateral dimensions, is applied to the skin and confined by some convenient arrangement. A few drops of water are then added, and a degree of heat is soon evolved sufficient for a caustic effect, if the lime be allowed to remain as long as the heat continues. This may be increased or diminished by increasing or diminishing the quantity of lime employed. The eschar formed is somewhat more than double the extent of the base of the moxa. (*Dublin Journ.*, Jan., 1842.)

Medical Use. Cauterization by fire, in the treatment of disease, has been commonly practised among savage and half civilized nations from the earliest periods of history, and has not been unknown as a remedy in the most polished communities. The ancient Egyptians and Greeks were acquainted with the use of moxa; and in China, Japan, and other countries of Asia, it

appears to have been employed from time immemorial. From these countries the early Portuguese navigators introduced it into Europe; and the term *moxa* is said to have been derived from their language, though supposed by some to be of Chinese origin. The true Chinese name is said to be *kiew*. (*Percy and Laurent*.) Some years since, the remedy became very popular in France, and attracted some attention in this country. It acts on the principle of revulsion; relieving deep-seated inflammation, and local irritation whether vascular or nervous, by inviting the current of excitement to the skin. In some cases it may also operate advantageously by the propagation of a stimulant impression to neighbouring parts in which the natural actions are enfeebled.

The celebrated Larrey was among those who contributed most to bring this remedy into repute. The diseases in which it was recommended by this author were amaurosis, loss of taste, deafness, paralytic affections of the muscular system, asthma, chronic catarrh and pleurisy, phthisis, chronic engorgement of the liver and spleen, rachitis, diseased spine, coxalgia, and other forms of scrofulous and rheumatic inflammation of the joints. It has also been used advantageously in neuralgia, and is applicable to chronic complaints generally, in which powerful external revulsion is indicated.

The parts of the body upon which, according to Larrey, it should not be applied are the cranium when protected only by the skin and pericranium; the eye-lids, nose, and ears; the skin over the larynx, trachea, and mammary glands, over superficial tendons, projecting points of bones, and articular prominences in which the capsular ligament might be involved; the anterior surface of the abdomen; and the genitals.

As a general rule it should be applied as near as possible to the seat of the disease; and, in neuralgic or paralytic cases, at the origin or over the course of the nerves proceeding to the part affected. Some advise that the cylinder be attached to the skin by some adhesive liquid; but a more general practice is to retain it in the proper position by a pair of forceps or other instrument. Larrey recommends that the skin around it be covered with a piece of moistened lint, having a hole in the centre to admit the base of the cylinder. The moxa should be set on fire at the summit, and the combustion sustained if necessary by the breath, the blow-pipe, or the bellows. The size of the cylinder should vary, according to the effect desired, from half an inch to an inch or more in diameter, and from a few lines to an inch in height. Any degree of effect may be obtained, from a slight inflammation to the death of the skin, by regulating the time during which the moxa is allowed to burn. When a slough is required, it should be suffered to burn until consumed. The first sensation experienced is not disagreeable; but the operation becomes gradually more painful, and towards the close is for a short time very severe. W.

MUCUNA. Sex. Syst. Diadelphia Decandria.—Nat. Ord. Fabaceæ or Leguminosæ.

Gen. Ch. *Calyx* campanulate, bilabiate; the lower lip trifid, with acute segments, the middle one longest; the upper lip broader, entire, obtuse. *Corolla* with the vexillum ascending, shorter than the wings and keel; the wings oblong, equal to the keel in length; the keel oblong, straight, acute. *Stamens* diadelphous, with five anthers oblong-linear, and five ovate, hirsute. *Legume* oblong, torose, bivalvular, with cellular partitions. *Seeds* roundish, surrounded circularly by a linear hilum. (*De Candolle.*)

Mucuna pruriens. De Cand., *Prodrom.* ii. 405; Lindley, *Flor. Med.* p. 254.—*Dolichos pruriens.* Willd. *Sp. Plant.* iii. 1041; Woodv. *Med. Bot.* p. 422.—*Stizolobium pruriens.* Persoon. This is a perennial climbing plant, with an herbaceous branching stem, which twines round the trees in its vicinity, and rises to a considerable height. The leaves are pinnately trifoliate, and stand on long footstalks placed alternately on the stem at the distance of a foot from each other. The leaflets are acuminate, smooth on their upper surface, and hairy beneath. The lateral leaflets are oblique at the base, the middle one somewhat rhomboidal. The flowers, which resemble those of the pea in form, are large, of a red or purplish colour, usually placed in threes on short peduncles, and hang from the axils of the leaves in pendent spikes about a foot in length. The fruit is a coriaceous pod, shaped like the Italic letter *f*, about four inches long, and covered with brown bristly hairs, which easily separate, and when handled stick in the fingers, producing an intense itching sensation. The plant is a native of the West Indies, and other parts of tropical America. It has been supposed to grow also in the East Indies; but the plant of that region is now considered a distinct species, and entitled *Mucuna prurita*. The part usually imported is the pod, of which the hairs are the officinal portion.

Medical Properties and Uses. These spiculæ are said to be possessed of powerful vermifuge properties, and are thought to act mechanically, by penetrating the worms. That they do act in this manner is evinced, as well by the result of direct experiment upon worms out of the body, as by the fact that neither the tincture nor decoction is in the slightest degree anthelmintic. Why the worms should be injured; and the mucous membrane of the stomach and bowels escape with impunity, is not satisfactorily explained. The medicine was first employed as a vermifuge by the inhabitants of the West Indies, and thence passed into British practice. The testimony in its favour is too strong to admit of any reasonable doubt as to its efficiency. It has been chiefly employed against the round worm; but all the different species which infest the alimentary canal have been expelled by its use. It is best administered mixed with some tenacious vehicle. The usual mode of preparing it is to dip the pods into syrup or molasses, and scrape off the hairs with the liquid, which is in a proper state for administration when it has attained the consistency of thick honey. The dose of this preparation is a tablespoonful for an adult, a teaspoonful for a child three or four years old, to be given every morning for three days, and then followed by a brisk cathartic.

The root of the *M. pruriens* (*M. prurita*) is said by Ainslie to be employed in the East Indies in the treatment of cholera; and both this part and the pods have been thought to possess diuretic properties. W.

Myristica moschata. Willd. *Sp. Plant.* iv. 869; Woodv. *Med. Bot.* p. 698. t. 238. *M. officinalis*. Linn. *Suppl.* 265; Lindley, *Flor. Med.* p. 21. The nutmeg tree is about thirty feet high, with numerous branches, and an aspect somewhat resembling that of the orange tree. The leaves stand alternately on short footstalks, are oblong oval, pointed, entire, undulated, obliquely nerved, bright green and somewhat glossy on their upper surface, whitish beneath, and of an aromatic taste. The flowers are male and female upon different trees. The former are disposed in axillary, peduncled, solitary clusters; the latter are single, solitary, and axillary; both are minute and of a pale yellowish colour. The fruit, which appears on the tree mingled with the flowers, is round or oval, of the size of a small peach, with a smooth surface, at first pale green, but yellow when ripe, and marked with a longitudinal furrow. The external covering, which is at first thick and fleshy, and abounds in an austere, astringent juice, afterwards becomes dry and coriaceous, and, separating into two valves from the apex, discloses a scarlet reticulated membrane or arillus, commonly called *mace*, closely investing a thin, brown, shining shell, which contains the kernel or *nutmeg*. Not less than eight varieties of this species are said by Crawford to be cultivated in the East Indies; but they have not been well defined.

The *Myristica moschata* is a native of the Moluccas and other neighbouring islands, and abounds especially in that small cluster distinguished by the name of Banda, whence the chief supplies of nutmegs have long been derived. The plant, however, is now cultivated in Sumatra, Java, Penang, and some other parts of the East Indies; and has been introduced into the Isle of France and Bourbon, the French colony of Cayenne, and some of the West India islands.

The tree is produced from the seed. It does not flower till the eighth or ninth year, after which it bears flowers and fruit together, without intermission; and is said to continue bearing for seventy or eighty years. Little trouble is requisite in its cultivation. A branch of the female tree is grafted into all the young plants when about two years old, so as to ensure their early fruitfulness. In the Moluccas the tree yields three crops annually. The fruit is gathered by the hand, and the outside covering is rejected as useless. The mace is then carefully separated, so as to break it as little as possible, is flattened, and dried in the sun, and afterwards sprinkled with salt water, with the view of contributing to its preservation. Its fine red colour is much impaired by drying. The nuts are dried in the sun or by ovens, and exposed to smoke, till the kernel rattles in the shell. They are then broken open, and the kernels having been removed, and steeped for a short time in a mixture of lime and water, probably in order to preserve them from the attack of worms, are next cleaned, and packed in casks or chests for exportation.

Nutmegs are brought to this country either directly from the East Indies, or indirectly through England and Holland. They are also occasionally imported in very small quantities from the West Indies.

Properties. The nutmeg, *nux moschata*, is of a roundish or oval shape, obtuse at the extremities, marked with vermicular furrows, of a grayish colour, hard, smooth to the touch, yielding readily to the knife or the grater, but not very pulverulent. When cut or broken it presents a yellowish surface, varied with reddish-brown, branching, irregular veins, which give to it a marbled appearance. These dark veins abound in oily matter, upon which the medicinal properties depend. The odour of nutmeg is delightfully fragrant, the taste warm, aromatic, and grateful. Its virtues are extracted by alcohol and ether. M. Bonastre obtained from 500 parts, 120 of a white insoluble oily substance (stearin), 38 of a coloured soluble oil (olein), 30 of volatile oil, 4 of acid, 12 of fecula, 6 of gum, 270 of lignin; and 20 parts were lost. (*Journ. de Pharm.* ix. 281.) The volatile oil is obtained by distillation with water. (See *Oleum Myristicæ*.) By pressure with heat an oily matter is obtained from the kernels, which becomes solid on cooling, and is commonly though erroneously called *oil of mace*.

It is said that nutmegs are often punctured and boiled in order to extract their essential oil, and the orifice afterwards closed so carefully as not to be discoverable unless by breaking the kernel. The fraud may be detected by their greater levity. They are also apt to be injured by worms, which, however, attack preferably those parts which are least impregnated with the volatile oil. We are told that the Dutch heat them in a stove in order to deprive them of the power of germinating, and thus prevent the propagation of the tree. The small and round nutmegs are preferred to those which are large and oval. They should be rejected when very light, with a feeble taste and smell, worm-eaten, musty, or marked with black veins.

A kind of nutmeg is occasionally met with, ascribed by some to a variety of the *M. moschata*, by others to a different species, which is distinguished from that just described by its much greater length, its elliptical shape, the absence of the dark brown veins, and its comparatively feeble odour, and disagreeable taste. It has been called *male* or *wild nutmeg*, the other being designated as the *female* or *cultivated nutmeg*.

The concrete or expressed oil of nutmeg (*MYRISTICÆ ADEPS*, *Ed.*), commonly called *oil of mace*, is obtained by bruising nutmegs, exposing them in a bag to the vapour of water, and then compressing them strongly between heated plates. A liquid oil flows out which becomes solid when it

cools. Nutmegs are said to yield from ten to twelve per cent. of this oil. The best is imported from the East Indies in stone jars. It is solid, soft, unctuous to the touch, of a yellowish or orange-yellow colour, more or less mottled, with the odour and taste of nutmeg. It is composed, according to Schrader, of 52·09 per cent. of a soft oily substance, yellowish or brownish, soluble in cold alcohol and ether; 43·75 of a white, pulverulent, inodorous substance, insoluble in these liquids; and 4·16 of volatile oil.

An inferior kind of expressed oil of nutmegs is prepared in Holland, and sometimes found in the shops. It is in hard, shining, square cakes, of a lighter colour than that from the East Indies, and with less smell and taste. It is supposed to be derived from nutmegs previously deprived of most of their volatile oil by distillation. An artificial preparation is sometimes substituted for the genuine oil. It is made by mixing together various fatty matters, such as suet, palm oil, spermaceti, wax, &c., adding some colouring substance, and giving flavour to the mixture by the volatile oil of nutmeg.

Mace (MACIS, Dub.) is in the shape of a flat membrane irregularly slit, smooth, soft, flexible, of a reddish or orange-yellow colour, and an odour and taste closely resembling those of nutmeg. It consists, according to M. Henry, of an essential oil in small quantity; a fixed oil, odorous, yellow, soluble in ether, insoluble in boiling alcohol; another fixed oil, odorous, red, soluble in alcohol and ether in every proportion; a peculiar gummy matter, analogous to amydin and gum, constituting one-third of the whole mass; and a small proportion of ligneous fibre. Mace yields a volatile oil by distillation, and a fixed oil by pressure. Neumann found the former heavier than water. The latter is less consistent than the fixed oil of nutmegs. Mace is inferior when it is brittle, less than usually divided, whitish or pale yellow, or with little taste and smell.

Medical Properties and Uses. Nutmeg unites with the medicinal properties of the ordinary aromatics, considerable narcotic power. In the quantity of two or three drachms it has been known to produce stupor and delirium; and dangerous if not fatal consequences are said to have followed its free use in India. It is employed to cover the taste or correct the operation of other medicines, but more frequently as an agreeable addition to farinaceous articles of diet, and to various kinds of drink in cases of languid appetite, and delicate stomach. It is usually given in substance, and is brought by grating to the state of a powder. *Mace* possesses properties essentially the same with those of nutmeg, but is less used as a medicine. The dose of either is from five to twenty grains. As the virtues of nutmeg depend chiefly if not exclusively on the volatile oil, the latter may be substituted, in the dose of two or three drops, whenever a liquid preparation is desirable. The expressed oil of nutmeg is occasionally used as a gentle external stimulant, and, though not admitted into the *Materia Medica* list of the London Pharmacopœia, is an ingredient in the *Emplastrum Picis* of that work.

The ancients were wholly unacquainted with nutmeg; and Avicenna is said to be the first author by whom it is noticed.

Gen. Ch. Calyx bell-shaped, five-toothed. Petals five, the upper one larger than the others. Germen longer than the corolla. Legume with one seed only at the point. Willd.

Myroxylon peruiferum. Willd. Sp. Plant. ii. 546; Lambert's Illustrations, A.D. 1821. p. 97. Myrospermum peruiferum. De Cand. Prodrum. ii. 95; Lindley, Flor. Med. p. 279. This is a tall and very beautiful tree, with a straight, smooth trunk, and branches nearly horizontal. The bark is of a gray colour, compact, heavy, and highly resinous; and has the aromatic flavour of the balsam. The leaves are alternate, and composed of two, three, four, and sometimes five pairs of leaflets, which are nearly opposite, ovate lanceolate, with a lengthened but somewhat blunt and emarginate apex, entire, smooth and shining, hairy on the under surface, marked with numerous transparent points, and placed on short footstalks. Many leaves terminate unequally, consisting of five, seven, or nine leaflets. The common petioles are rather thick and hairy. The flowers are white or rose-coloured, and disposed in axillary racemes, longer than the leaves. The fruit is a pendulous, straw-coloured legume, club-shaped, somewhat curved, terminating in the curved style, and globular near the extremity, where there is a single cell, containing a crescent-shaped seed.

The tree is a native of the warmer regions of South America, growing in various parts of Peru and New Granada, where it is called *quinquino* by the natives. The wood is employed in building, and is valuable for its durability. The bark and fruit are used to perfume apartments. The tree yields by incision a balsamic juice, which, when received in bottles, may be preserved in a liquid state for some years. This is called *white liquid balsam*. When this juice is deposited in mats or calabashes, it becomes concrete, and acquires the name of *dry white balsam*, thought by some to be identical with *balsam of Tolu*. By boiling the bark in water, a dark coloured liquid is procured, which retains its fluid consistence, and is called *black Peruvian balsam*. According to Ruiz, from whose account the above details were derived, "there is no difference in these three balsams, excepting in the name, colour and consistence." It is only the dark coloured liquid that is known with us by the name of *balsam of Peru*, and to this the following remarks are confined.

In stating that it is procured by boiling the bark in water, Ruiz does not speak from his own knowledge. A general opinion is, that it is prepared by decoction from the smaller branches. As brought into the United States, it is usually in tin canisters, with a whitish scum upon its surface, and more or less deposit, which, however, is dissolved with the aid of heat.

In a communication by M. Guibourt to the Society of Pharmacy at

Paris, it is stated, on the authority of M. Bazire, that a product, exactly resembling the dark coloured Peruvian balsam of commerce, is collected largely in Guatemala, and thence sent to Peru. It is obtained from a tree belonging to the genus *Myrospermum* of Jacquin—*Myroxylon* of Linnæus—but specifically different from the *M. Peruiferum*.

Properties. Balsam of Peru is viscid like syrup or honey, of a dark reddish-brown colour, a fragrant odour, and a warm bitterish taste, leaving when swallowed a burning or prickling sensation in the throat. Its sp. gr. is from 1.14 to 1.15. When exposed to flame it takes fire, diffusing a white smoke, and a fragrant odour. Consisting chiefly of resin, essential oil, and benzoic acid, it is properly considered a balsam, though probably altered by heat. Alcohol in large proportion entirely dissolves it. Boiling water extracts the benzoic acid. From 1000 parts of the balsam, Stoltze obtained 24 parts of a brown nearly insoluble resinous matter, 207 of resin readily soluble, 690 of oil, 64 of benzoic acid, 6 of extractive matter, and a small proportion of water. The oil he considers to be of a peculiar nature, differing from the volatile, the fixed, and the empyreumatic oils. Results of a different character were obtained by Fremy, who maintains that the acid contained in the balsam is *cinnamic* and not benzoic acid; but the experiments and inferences of this chemist require confirmation.

Medical Properties and Uses. This balsam is a warm, stimulating tonic and expectorant; and has been recommended in chronic catarrhs, certain forms of asthma, phthisis, and other pectoral complaints attended with debility. It has also been used in gonorrhœa, leucorrhœa, amenorrhœa, chronic rheumatism, and palsy. At present, however, it is little employed by American physicians. As an external application it has been found beneficial in chronic indolent ulcers. The dose is half a fluidrachm. It is best administered diffused in water by means of sugar and the yolk of eggs or gum Arabic.

MYRRHA. U.S., Lond., Ed., Dub.

Myrrh.

“The concrete juice of *Balsamodendron Myrrha*.” *U.S.* “*Balsamodendron Myrrha. Gummi-resina.*” *Lond.* “Gummy-resinous exudation of *Balsamodendron Myrrha*.” *Ed.*

Myrrhe, *Fr.*, *Germ.*; Mirra, *Ital.*, *Span.*; Murr, *Arab.*; Bowl, *Hindoost.*

Though myrrh has been employed from the earliest periods of history, the plant which yields it has not been certainly known till a very recent date. The *Amyris Katsaf* of Forskhal, seen by that traveller in Arabia, was supposed by him to be the myrrh tree, but without sufficient evidence. More recently Ehrenberg, a German traveller, met on the frontiers of Arabia Felix with a plant, from the bark of which he collected a gum-resin precisely similar to the myrrh of commerce. From specimens of the plant taken by Ehrenberg to Germany, Nees of Esenbeck referred it to the genus *Balsamodendron* of Kunth, and named it *Balsamodendron Myrrha*. This genus was formed by Kunth from the *Amyris*, and includes the *Amyris Katsaf* of Forskhal, which may possibly also produce a variety of myrrh. The new genus differs from the *Amyris*, chiefly in having the stamens beneath instead of upon the germ. It is not thought by De Candolle sufficiently distinct. For the generic character of *Amyris*, see *Elemi*.

Balsamodendron Myrrha. Fée, *Cours d' Hist. Nat. Pharm.* i. 641.

This is a small tree, with a stunted trunk, covered with a whitish-gray bark, and furnished with rough abortive branches terminating in spines. The leaves are ternate, consisting of obovate, blunt, smooth, obtusely denticulate leaflets, of which the two lateral are much smaller than that at the end. The fruit is oval lanceolate, pointed, longitudinally furrowed, of a brown colour, and surrounded at its base by the persistent calyx. The tree grows in Arabia Felix, in the neighbourhood of Gison, in dwarfish thickets, interspersed among the *Acaciæ* and *Euphorbiæ*. The juice exudes spontaneously, and concretes upon the bark.

Formerly the best myrrh was brought from the shores of the Red Sea by way of Egypt and the Levant, and hence received the name of *Turkey myrrh*; while the inferior qualities were imported from the East Indies, and commonly called *India myrrh*. These titles have ceased to be applicable; as myrrh of all qualities is now brought from the East Indies, whither it is carried from Arabia and probably from Abyssinia. It is usually imported in chests containing between one and two hundred weight. Sometimes the different qualities are brought separate; but sometimes also more or less mingled, so that it is necessary to assort them by the hand. Only the best kind should be selected for medical use.

Properties. Myrrh is in small irregular fragments or tears, or in larger masses composed apparently of agglutinated portions differing somewhat in their shade of colour. The pieces are exceedingly irregular in shape and size, being sometimes not larger than a pea, and sometimes, though rarely, almost as large as the fist. They are often powdery upon the surface. When of good quality, myrrh is reddish-yellow or reddish-brown and translucent, of a strong peculiar somewhat fragrant odour, and a bitter aromatic taste. It is brittle and pulverizable, presenting, when broken, a shining surface, which in the larger masses is very irregular, and sometimes exhibits opaque whitish or yellowish veins. In powder it is of a light yellowish colour. Under the teeth it is at first friable, but soon softens and becomes adhesive. It is inflammable, but does not burn vigorously; and is not fusible by heat. Its specific gravity is stated at 1.36. The inferior kind of myrrh, commonly called *India myrrh*, is in pieces much darker than those described, more opaque, less odorous, and often abounding with impurities. We have seen pieces of India myrrh enclosing large crystals of common salt, as if the juice might have fallen from the tree and concreted upon the ground, where this mineral abounds. Pieces of *bdellium* and other gummy or resinous substances of unknown origin are often mixed with it. It is best to purchase myrrh in mass; as in powder it is very liable to adulterations which are not easily detected.

Myrrh is partially soluble in water, alcohol, and ether. Triturated with water it forms an opaque yellowish or whitish emulsion, which deposits the larger portion of the myrrh upon standing. Its alcoholic tincture is rendered opaque by the addition of water, but throws down no precipitate. According to Neumann, alcohol and water severally extract the whole of its odour and taste. By distillation a volatile oil rises, having the peculiar flavour of myrrh, and leaving the residue in the retort simply bitter. The gum-resin is soluble in solutions of the alkalies, and when triturated with them in a crystalline state forms a tenacious liquid. Hence carbonate of potassa may be used to facilitate its suspension in water. Braconnot found 2.5 parts of volatile oil and 23 parts of a bitter resin, 46 of soluble, and 12 of insoluble gum in the hundred. (*Ann. de Chim.* lxxvii. 52.) Pelletier gives as the result of his analysis, 34 per cent. of resin, with a small proportion of volatile oil, and 66 per cent. of gum. According to Brandes, it contains in one

hundred parts, 2·60 of volatile oil, 22·24 of a soft bitter resin, soluble in ether, 5·56 of a tasteless resin, insoluble in ether, 54·38 of gum with traces of various salts, 9·30 of tragacanthin (bassorin), besides salts of potassa and lime, water, and impurities.

Medical Properties and Uses. Myrrh is a stimulant tonic, with some tendency to the lungs, and perhaps to the uterus. Hence it is employed as an expectorant and emmenagogue, in debilitated states of the system, in the absence of febrile excitement or acute inflammation. The complaints in which it is usually administered are chronic catarrh, phthisis pulmonalis, humoral asthma, other pectoral affections in which the secretion of mucus is abundant but not easily expectorated, chlorosis, amenorrhœa, and the various affections connected with this state of the uterine function. It is generally given combined with the chalybeates or other tonics, and in amenorrhœa very frequently with aloes. It is used also as a local application to spongy gums, the aphthous sore mouth of children, and various kinds of unhealthy ulcers. The dose is from ten to thirty grains, and may be given in the form of powder or pill, or suspended in water, as in the famous antihectic mixture of Dr. Griffith, which has been introduced into the Pharmacopœias with the title of *Mistura Ferri Composita*. The watery infusion is also sometimes given, and an aqueous extract has been recommended as milder than the medicine in substance. The tincture is used chiefly as an external application.

STRYCHNOS. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Apocynaceæ.

Gen. Ch. Corolla five-cleft. Berry one-celled, with a ligneous rind. *Willd.*

Strychnos Nux vomica. Willd. *Sp. Plant.* i. 1052; Woodv. *Med. Bot.* p. 222. t. 79. This tree is of a moderate size, with numerous strong branches covered with a smooth, dark gray bark. The young branches are long, flexuous, very smooth, dark green, and furnished with oval roundish, entire, smooth, and shining leaves, having three or five ribs, and placed opposite to each other on short footstalks. The flowers are small, white, funnel-shaped, and disposed in terminal corymbs. The fruit is a round berry, about as large as an orange, covered with a smooth, yellow or orange-coloured, hard, fragile rind, and containing numerous seeds embedded in a juicy pulp.

The tree is a native of the East Indies, growing in Bengal, Malabar, on the coast of Coromandel, in Ceylon, in numerous islands of the Indian Archipelago, in Cochin-china, and other neighbouring countries. The wood and the root are very bitter, and employed in the East Indies for the cure of intermittents. The *radices colubrinæ*, and *lignum colubrinum*,

of the older writers, which have been long known in Europe as narcotic poisons, are ascribed by some writers to this species of *Strychnos*, under the impression that it is identical with the *S. Colubrina*, to which Linnæus refers them. They have been ascertained by Pelletier and Caventou to contain a large quantity of strychnia. The bark is said by Dr. O'Shaughnessy, Professor of Chemistry in the Medical College of Calcutta, to answer exactly to the description given by authors of the *false angustura*, and, like that, to contain a large quantity of brucia. The identity of the two barks has been confirmed by Dr. Pereira, who has had an opportunity of comparing specimens of them together. (See *Angustura*.) The only official portion of the plant is the seeds.

These are circular, about three quarters of an inch in diameter, and two or three lines in thickness, flat, or slightly convex on one side and concave on the other. They are thickly covered with fine, silky, shining, ash-coloured or yellowish-gray hairs, attached to a thin fragile coating, which closely invests the interior nucleus or kernel. This is very hard, horny, usually whitish and semitransparent, sometimes dark coloured and opaque, and of very difficult pulverization. The powder is yellowish-gray, and has a faint sweetish odour. The seeds are destitute of odour, but have an acrid very bitter taste, which is much stronger in the kernel than in the investing membrane. They impart their virtues to water, but more readily to diluted alcohol. *Nux vomica* has been analysed by several chemists, but most accurately by Pelletier and Caventou, who discovered in it two alkaline principles, *strychnia* and *brucia*, united with a peculiar acid which they named *igasuric*. Its other constituents are a yellow colouring matter, a concrete oil, gum, starch, bassorin, and a small quantity of wax. *Strychnia* and *brucia* are its active principles.

Strychnia was discovered by Pelletier and Caventou, A. D. 1818, both in the *nux vomica* and bean of *St. Ignatius*, and received its name from the generic title of the plants (*Strychnos*), to which these two products belong. According to these chemists, it exists much more abundantly in the bean of *St. Ignatius* than in the *nux vomica*, the former yielding 1.2 per cent., the latter only 0.4 per cent. of the alkali. For an account of its properties and mode of preparation, see *Strychnia*, in the second part of this work.

Brucia was discovered by Pelletier and Caventou, first in the bark called *false angustura*, in combination with gallic acid, and subsequently, associated with strychnia in the form of *igasurates*, in the *nux vomica* and bean of *St. Ignatius*. It is crystallizable; and its crystals are said to contain 18.41 per cent. of water. It is without smell, but of a permanent, harsh, very bitter taste; soluble in 850 parts of cold, and 500 of boiling water; very soluble in alcohol, whether hot or cold; but insoluble in ether and the fixed oils, and only slightly dissolved by the volatile oils. It is permanent in the air, but melts at a temperature a little above that of boiling water, and on cooling congeals into a mass resembling wax. It forms crystallizable salts with the acids. Concentrated nitric acid produces with brucia or its salts an intense crimson colour, which changes to yellow by heat, and upon the addition of protochloride of tin becomes violet. These effects are peculiar to brucia, and, if produced with strychnia, evince the presence of the former alkali. Brucia is analogous in its operation to strychnia, but possesses, according to M. Andral, only about one-twelfth of its strength, when the latter principle is entirely pure. It is therefore seldom employed; and it is unnecessary to insert a process for its preparation. It is sufficient to observe, that it may be procured from false *Angustura* bark, in a manner

essentially the same with that in which strychnia is procured from the nux vomica; with this difference, that the alcoholic extract, obtained from the precipitate produced by lime or magnesia, should be treated with oxalic acid, and subsequently with a mixture of rectified alcohol and ether, which take up the colouring matter, leaving the oxalate or brucia. This is decomposed by magnesia, and the brucia is separated by alcohol, which, by spontaneous evaporation, yields it in the state of crystals. According to Dr. Fuss, whose experiments were repeated and confirmed by Professor Erdman, brucia is not a distinct alkali, but merely a compound of strychnia and resin. (*Pereira's Materia Medica.*)

Medical Properties and Uses. Nux vomica is very peculiar in its operation upon the system. In very small doses, frequently repeated, it is tonic, and is said to be diuretic, and occasionally diaphoretic and laxative. When it is given in larger doses, so as to bring the system decidedly under its influence, its action appears to be directed chiefly to the nerves of motion, probably through the medium of the spinal marrow. Its operation is evinced at first by a feeling of weight and weakness, with tremblings in the limbs, and some rigidity on attempting motion. There seems to be a tendency to permanent involuntary muscular contraction, as in tetanus; but at the same time frequent starts or spasms occur, as if the patient had received a shock of electricity. These spasms are at first brought on by some exciting cause, as by a slight blow or an attempt to move; but, if the medicine is persevered in, occur without extraneous agency, and are sometimes frequent and violent. In severe cases there is occasionally general rigidity of the muscles. A sense of heat in the stomach, constriction of the throat and abdomen, tightness of the chest, and retention of urine are frequently experienced, to a greater or less extent, according to the quantity of the medicine administered. It sometimes, also, produces pain in the head, vertigo, and dimness of vision, thus proving that it is capable of acting on the brain as well as the spinal marrow. Sensations analogous to those attending imperfect palsy, such as formication, tingling, &c., are experienced in some cases upon the surface. The pulse is not materially affected, though sometimes slightly increased in frequency. In over doses, the medicine is capable of producing fatal effects. Given to the inferior animals in fatal doses it produces great anxiety, difficult and confined breathing, retching to vomit, universal tremors, spasmodic action of the muscles, and ultimately violent convulsions. Death is supposed to take place from a suspension of respiration, resulting from a spasmodic constriction of the muscles concerned in the process. Upon dissection, no traces of inflammatory action are observable, unless large quantities of the nux vomica have been swallowed, when the stomach appears inflamed. A division of the spinal marrow near the occiput, does not prevent the peculiar effects of the medicine, so that the intervention of the brain is not essential to its action. That it enters the circulation and is brought into contact with the parts upon which it acts, is rendered evident by the experiments of Magendie and others.

Nux vomica has long been employed in India, and was known as a medicine to the Arabian physicians. On the continent of Europe, it has at various times been recommended as an antidote to the plague, and as a remedy in intermittents, dyspepsia, pyrosis, gastrodynia, dysentery, colica pictonum, worms, mania, hypochondriasis, hysteria, rheumatism, and hydrophobia. It is said to have effectually cured obstinate spasmodic asthma. Its peculiar influence upon the nerves of motion, to which the public attention was first called by Magendie, suggested to M. Fouquier, a French phy-

sician, the application of the remedy to paralytic affections; and his success was such as to induce him to communicate to the public the result of his experience. Others have subsequently employed it with variable success; but the experience in its favour so much predominates, that it may now be considered a standard remedy in palsy. It is a singular fact, attested by numerous witnesses, that its action is directed more especially to the paralytic part, exciting contraction in this before it is extended to other muscles. The medicine, however, should be administered with judgment, and never given in cases depending on inflammation or organic lesion of the brain or spinal marrow, until after the removal of the primary affection by bleeding or other depletory measures. It has been found more successful in general palsy and paraplegia than in hemiplegia, and has frequently effected cures in palsy of the bladder, incontinence of urine from paralysis of the sphincter, amaurosis, and other cases of partial palsy, and has been employed with asserted success in prolapsus ani and impotence. It has recently been recommended in neuralgia.

Nux vomica may be given in powder in the dose of five grains, repeated three or four times a day, and gradually increased till its effects are experienced. In this form, however, it is very uncertain; and fifty grains have been given with little or no effect. It is most readily reduced to powder by filing or grating, and the raspings may be rendered finer by first steaming them, then drying them by stove heat, and lastly rubbing them in a mortar. The Edinburgh College directs that the seeds should be first well softened with steam, then sliced, dried, and ground in a coffee-mill.

The alcoholic extract is more convenient and more certain in its operation. From half a grain to two grains may be given in the form of pill, repeated as before, and gradually increased. (See *Extractum Nucis Vomicae*.) The watery extract is comparatively feeble.

Strychnia has recently been much used, and possesses the advantage of greater certainty and uniformity of action. Its effects are precisely similar. With the exception of prussic acid, it is perhaps the most violent poison in the catalogue of medicines, and should therefore be administered with great caution. The dose is from one-twelfth to one-sixth of a grain, repeated twice or three times a day, and gradually increased. Even the smallest quantity mentioned sometimes produces spasmodic symptoms, and these generally occur when the dose is augmented to half a grain, three times a day. The system is not so soon habituated to its impression as to that of the narcotics generally, so that after its effects are experienced it is unnecessary to go on increasing the dose. *Strychnia* has been applied externally with advantage in amaurosis. It should be sprinkled upon a blistered surface near the temples, in the quantity of half a grain or a grain morning and evening; and the quantity may be gradually augmented. The best form of administration is that of pill, in consequence of the excessive bitterness of the solution. *Strychnia* may, however, be given, dissolved in alcohol, or in water by the intervention of an acid.

Brucia may be used for the same purposes with *strychnia* in the dose of one grain twice or three times a day. Dr. Bardsley found that the quantity of two grains three or four times a day, was seldom exceeded without the occurrence of the characteristic effects of the medicine. Magendie has found this alkali very useful in small doses as a tonic. He employed for this purpose one-eighth of a grain, frequently repeated.

W.

OLEA.

Oils.

These are liquid or solid substances, characterized by an unctuous feel, inflammability, and the property of leaving a greasy stain upon paper. They are divided into two classes, the *fixed* and *volatile*, distinguished, as their names imply, by their different habitudes in relation to the vaporizing influence of caloric.

1. OLEA FIXA. *Fixed Oils.*

These are termed OLEA EXPRESSA, *expressed oils*, in the Dublin Pharmacopœia, in which alone they are designated as a class.

The fixed oils, though existing in greater or less proportion in various parts of plants, are furnished for use exclusively by the fruit; and, as a general rule, are most abundant in the dicotyledonous seeds. They are obtained either by submitting the bruised seeds to pressure in hempen bags, or by boiling them in water, and skimming off the oil as it rises to the surface. When pressure is employed, it is customary to prepare the seeds for the press, by exposing them to a moderate heat, so as to render the oil more liquid, and thus enable it to flow out more readily.

The consistence of the fixed oils varies from that of tallow to perfect fluidity, but by far the greater part are liquid at ordinary temperatures. They are somewhat viscid, transparent, and usually of a yellowish colour, which disappears when they are treated with animal charcoal. When pure they have little taste or smell. They are lighter than water, varying in specific gravity from 0.913 to 0.936. (*Berzelius.*) They differ very much in their point of congelation, olive oil becoming solid a little above 32° F., while linseed oil remains fluid at 4° below zero. They are not volatilizable without decomposition. At about 600° they boil, and are converted into vapour, which, when condensed, is found to contain a large proportion of oleic and margaric acids, together with benzoic acid, another volatile acid, and an empyreumatic oil. Exposed to a red heat, in close vessels, they yield, among other products of the destructive distillation of vegetables, a large quantity of the combustible compounds of carbon and hydrogen. Heated in the open air they take fire, burning with a bright flame, and producing water and carbonic acid. When kept in air-tight vessels, they remain unchanged for a great length of time, but exposed to the atmosphere, they attract oxygen, and ultimately become concrete. Some, in drying, lose their unctuous feel, and are converted into a transparent, yellowish, flexible solid. These are called *drying oils*. Others, especially such as contain mucilaginous impurities, become rancid, acquiring a sharp taste, and unpleasant smell. This change is owing to the formation of an acid, from which the oil may be freed by boiling it for a short time with hydrate of magnesia and water. The fixed oils are insoluble in water, but are miscible with that fluid by means of mucilage, forming mixtures which are called emulsions. They are in general very sparingly soluble in alcohol, but readily dissolved by ether, which serves to separate them from other vegetable proximate principles. By the aid of heat they dissolve sulphur and phosphorus. Chlorine and iodine are converted by them into muriatic and hydriodic acids, which reacting upon the oils increase their consistence, and ultimately render them as hard as wax. The stronger acids decompose them, giving

rise, among other products, to the oleic and margaric acids. Boiled with diluted nitric acid, they are converted into malic and oxalic acids, besides other substances usually resulting from the action of this acid upon vegetable matter. Several acids are dissolved by them without producing any sensible change. They combine with salifiable bases; but at the moment of combination undergo a change, by which they are converted into a peculiar substance called glycerin, and into the oleic and margaric acids, which unite with the base employed. The compounds of these acids with potassa and soda are called soaps. (See *Sapo* and *Emplastrum Plumbi*.) The fixed oils dissolve many of the vegetable alkalies, the volatile oils, resin, and other proximate principles of plants. They consist of two distinct substances, one of which is liquid at ordinary temperatures, and therefore called *olein*, the other solid, and called *margarin*. The more solid ingredient of the vegetable oils was originally called *stearin*, the name applied to the analogous ingredient of the animal oils, with which it was supposed by Chevreul, the discoverer of this complex constitution of oleaginous substances, to be identical. It has, however, been found to be essentially different, yielding margaric acid in the process of saponification, while stearin yields stearic acid; and a new name has accordingly been conferred upon it. For the mode of separating the liquid from the solid principles of oils, as well as for an account of their distinctive properties, the reader is referred to the article *Adeps*. Margarin is distinguished from stearin by its greater fusibility, and by its solubility in cold ether; and the two principles may be separated by the action of boiling ether, which dissolves both, but deposits the stearin upon cooling, while it retains the margarin and yields it by evaporation. These principles, however, are thought by Berzelius not to be absolutely identical in the different oils; as they have different points of congelation and liquefaction, according to the substance from which they are derived.* By the action of nitric acid or nitrous acid fumes, olein is converted into a deep-yellow butyraceous mass. If this be treated with warm alcohol, a deep orange-red oil is dissolved, and a peculiar fatty matter remains, called *elaïdin*. It is white, fusible at 97°, insoluble in water, sparingly soluble in alcohol, readily soluble in ether, and converted, by saponification with the alkalies, into a peculiar acid, denominated *elaïdic* acid, and into glycerin. (*Kane's Chemistry*.) The view now taken of the nature of olein, margarin, stearin, elaïdin, and other similar fatty matters, is that they are compounds of the oleic, margaric, stearic, elaïdic acids, &c., with glycerin; and in the process of saponification, the alkali takes the oily acid and sets glycerin free.

* Some interesting results in relation to the fixed oils have been obtained by MM. Pelouze and Boudet, and published in the *Journal de Pharmacie*, tom. xxiv. p. 385. According to these chemists, the variable fusibility of the margarin and stearin of fixed oils, which has induced some chemists to believe that they are severally not entirely identical as obtained from different oils, is owing to the existence of definite combinations of margarin and stearin respectively with olein; and each of these principles, in a state of purity, is probably the same from whatever source derived, whether from vegetable or from animal oils. Thus they found the same margarin in palm oil and in human fat. But there appear to be two distinct kinds of olein, one existing in the *drying oils*, as li-seed oil, the oil of poppies, &c., the other in the oils which are not drying, as in olive oil, almond oil, human fat, and lard. These two forms of olein are different in their solubility in different menstrua, and in the circumstances that one is drying and the other not so, that one remains liquid under the action of nitrous acid, while the other is converted by it into a solid substance called *elaïdin*, and finally that the former contains much less hydrogen than the latter. Besides, the oleic acid formed in the process of saponification by these two kinds of olein is decidedly different, inasmuch as, in the one case, it is converted by nitrous acid into *elaïdic* acid, and in the other is not thus changed.—*Note to Fourth Edition.*

The ultimate constituents of the fixed oils are carbon, hydrogen, and oxygen, the hydrogen being in much larger proportion than is necessary to form water with the oxygen. Those which are least fusible contain most carbon and least oxygen; and, according to Saussure, their solubility in alcohol is greater in proportion to their amount of oxygen. (*Berzelius*.) Some of them contain a very minute proportion of nitrogen.

2. OLEA VOLATILIA. *Volatile oils.*

These are sometimes called *distilled oils*, from the mode in which they are usually procured; sometimes *essential oils*, from the circumstance that they possess, in a concentrated state, the properties of the plants from which they are derived. In the Pharmacopœias of the United States and London, the former title has been adopted; in that of Dublin, the latter; the Edinburgh College uses the term *volatile oils*.

They exist in all odoriferous vegetables, sometimes pervading the whole plant, sometimes confined to a single part; in some instances contained in distinct cellules, and preserved after desiccation, in others formed upon the surface, as in many flowers, and exhaled as soon as they are formed. Occasionally two or more are found in different parts of the same plant. Thus the orange tree produces one volatile oil in its leaves, another in its flowers, and a third in the rind of its fruit. In a few instances, when existing in distinct cellules, they may be obtained by pressure, as from the rind of the lemon and orange; but they are generally procured by distillation with water. (See *Olea Destillata*.) Sometimes the volatile oils obtained by distillation are formed, during the process, out of substances of a different nature pre-existing in the plant. This is the case with the oils of bitter almonds and mustard.

The volatile oils are usually yellowish, but sometimes brown, red, green, or even blue, and occasionally colourless. They have a strong odour, resembling that of the plants from which they were procured, though generally less agreeable. Their taste is hot and pungent, and when they are diluted is often gratefully aromatic. The greater number are lighter than water; some are heavier; and their sp. gr. varies from 0.847 to 1.17.* They partially rise in vapour at ordinary temperatures, diffusing their peculiar odour, and are completely volatilized by heat. Their boiling point is various, generally as high as 320° F. and sometimes higher; but most of them rise readily with the vapour of boiling water. When distilled alone, they almost always undergo partial decomposition. They differ also in their point of congelation. A few are solid at ordinary temperatures, several become so at 32° F., and many remain liquid considerably below this point. Heated in the open air, the volatile oils take fire, and burn with a bright flame attended with much smoke. Exposed at ordinary temperatures, they absorb oxygen, assume a deeper colour, become thicker and less odorous, and are ultimately converted into resin. This change takes place most rapidly under the influence of light. Before the alteration is complete, the remaining portion of oil may be recovered by distillation. Some of them, instead of resin, form well characterized acids by combination with oxygen.

The volatile oils are very slightly soluble in water. Agitated with this fluid they render it milky; but separate upon standing, leaving the water impregnated with their odour and taste. This impregnation is more complete when water is distilled with the oils, or from the plants containing

* The oil of the *Gaultheria procumbens*, a native plant, is said to have the extraordinary sp. gr. of 1.17. (*Journ. of the Phil. Col. of Pharm.* iii. 199.)

them. Trituration with magnesia or its carbonate renders them much more soluble, probably in consequence of presenting, by their minute division, a more extensive surface to the action of the solvent. The intervention of sugar also greatly increases their solubility, and affords a convenient method of preparing them for internal use. Most of them are very soluble in alcohol, and in a degree proportionate to its freedom from water. The oils which contain no oxygen are scarcely soluble in diluted alcohol, and, according to Saussure, their solubility generally in this liquid is proportionate to the quantity of oxygen which they contain. They are readily dissolved by ether.

The volatile oils dissolve sulphur and phosphorus with the aid of heat, and deposit them on cooling. By long boiling with sulphur they form brown, unctuous, fetid substances, formerly called *balsams of sulphur*. They absorb chlorine, which converts them into resin, and then combines with the resin. Iodine produces a similar effect. They are decomposed by the strong mineral acids, and unite with several of those from the vegetable kingdom. When treated with a caustic alkali, they are converted into resin, which unites with the alkali to form a kind of soap. Several of the metallic oxides, and various salts which easily part with oxygen, convert them into resin. The volatile oils dissolve many of the proximate principles of plants and animals, such as the fixed oils and fats, resin, camphor, and several of the vegetable alkalies.

The volatile, like the fixed oils, consist of distinct principles, which are congealed at different temperatures, and may be separated by compressing the frozen oil between the folds of bibulous paper. The solid matter remains within the folds; and the fluid is absorbed by the paper, from which it may be separated by distillation with water. The name of *stearoptene* has been proposed for the former, that of *eleoptene* for the latter. The solid crystalline substances deposited by certain volatile oils upon standing, usually considered as camphor, are examples of stearoptene. Some of these are isomeric with the oils in which they are formed, others are oxides. Some oils, under the influence of water, deposit crystalline bodies which appear to be hydrates of the respective oils.

The ultimate constituents of the volatile oils are usually carbon, hydrogen, and oxygen. Some, as the oils of turpentine and copaiba, in their purest state, contain only carbon and hydrogen. Several, according to De Saussure, have nitrogen in their composition; and the oils of horse-radish and mustard contain sulphur.

The volatile oils are often sophisticated. Among the most common adulterations are fixed oils, resinous substances, and alcohol. The presence of the fixed oils may be known by the permanent greasy stain which they leave on paper, while that occasioned by a pure volatile oil disappears entirely when exposed to heat. They may also in general be detected by their comparative insolubility in alcohol. Both the fixed oils and resins are left behind when the adulterated oil is distilled with water. If alcohol is present, the oil becomes milky when agitated with water, and after the separation of the liquids, the water occupies more space, and the oil less than before. The following method of detecting alcohol has been proposed by M. Beral. Put twelve drops of the suspected oil in a perfectly dry watch-glass, and add a piece of potassium about as large as the head of a pin. If the potassium remain for twelve or fifteen minutes in the midst of the liquid, there is either no alcohol present, or less than four per cent. If it disappear in five minutes, the oil contains more than four per cent. of alcohol; if in less than a minute, twenty-five per cent. or more. M. Borsarelli employs chloride of calcium for the same

purpose. This he introduces in small pieces, well dried and perfectly free from powder, into a small cylindrical tube, closed at one end, and about two-thirds filled with the oil to be examined, and heats the tube to 212° , occasionally shaking it. If there be a considerable proportion of alcohol, the chloride is entirely dissolved, forming a solution which sinks to the bottom of the tube; if only a very small quantity, the pieces lose their form and collect at the bottom in a white adhering mass; if none at all, they remain unchanged. (*Journ. de Pharm.* xxvi. 429.) Sometimes volatile oils of little value are mixed with those which are costly. The taste and smell afford in this case the best means of detecting the fraud. The specific gravity of the oils may also serve as a test of their purity. When oils, of which one is lighter and one heavier than water, are mixed, they are separated by long agitation with this fluid, and will take a place corresponding to their respective specific gravities. But it sometimes happens that an unadulterated oil may thus be separated into two portions. When oil of turpentine is used as the adulteration, it may be known by remaining in part undissolved, when the mixture is treated with three or four times its volume of alcohol of the sp. gr. 0.84.

Volatile oils may be preserved without change in small well-stopped bottles, entirely filled with the oil, and excluded from the light. W.

OLEUM AMYGDALÆ. U.S.

Oil of Almonds.

“The fixed oil of the kernels of *Amygdalus communis*.” U.S.

Off. Syn. AMYGDALÆ OLEUM. *Amygdalus communis.* *Var. α.* *Var. β.* *Oleum ab alterutriusque nucleis expressum.* *Lond.;* OLEUM AMYGDALARUM, *Dub.*

Huile d'amandes, Fr.; Mandelöl, *Germ.;* Olio di mandorle, *Ital.;* Aceyte de almen-dras, *Span.*

See AMYGDALA.

This oil is obtained equally pure from sweet and bitter almonds. In its preparation, the almonds, after having been deprived of a reddish-brown powder adhering to their surface, by rubbing them together in a piece of coarse linen, are ground in a mill resembling a coffee-mill, or bruised in a stone mortar, and then submitted to pressure in canvass sacks between plates of iron slightly heated. The oil, which is at first turbid, is clarified by rest and filtration. The Dublin College directs the oil to be prepared by bruising the almonds, and then expressing without heat. Sometimes the almonds are steeped in very hot water, deprived of their cuticle, and dried in a stove previously to expression. The oil is thus obtained free from colour, but in no other respect better. Bitter almonds, when treated in this way, are said to impart a smell of hydrocyanic acid to the oil. With regard to these, therefore, the process is objectionable. M. Boullay obtained fifty-four per cent. of oil from sweet almonds, Vogel twenty-eight per cent. from bitter almonds.

The oil of almonds is clear and colourless, or slightly tinged of a greenish-yellow, is nearly inodorous, and has a bland sweetish taste. It remains liquid at temperatures considerably below the freezing point of water. Its sp. gr. is from 0.917 to 0.92. From the statement of Braconnot it appears to contain 76 per cent. of olein and 24 of margarin.

It may be used for the same purposes with olive oil; and, when suspended in water by means of mucilage or the yolk of eggs and loaf sugar, forms a

very pleasant emulsion, useful in catarrhal and other pulmonary affections attended with cough. From a fluidrachm to a fluidounce may be given at a dose.

OLEUM BERGAMII. *U. S.*

Oil of Bergamot.

“The volatile oil of the rind of the fruit of *Citrus Limetta* (*De Candolle*).” *U. S.*

Off. Syn. BERGAMII OLEUM. *Citrus Limetta Bergamium. Oleum è fructûs cortice destillatum. Lond.;* BERGAMOTÆ OLEUM. Volatile oil of the rind of the fruit of *Citrus Limetta. Ed.*

Huile de Bergamotte. Fr.; Bergamottöl, Germ.; Oleo di bergamotta, Ital.

CITRUS. See AURANTII CORTEX.

Citrus Limetta. *De Cand. Prodrôm. i. 539.* The bergamot tree has been ranked by botanists generally among the lemons, but is now considered as a variety of the *Citrus Limetta* of Risso, and is so placed by *De Candolle*. It has oblong, ovate, dentate, acute or obtuse leaves, somewhat paler on the under than the upper surface, and with footstalks more or less winged or margined. The flowers are white, and usually small; the fruit pyriform or roundish, pale yellow, terminated by an obtuse point, with a sourish pulp, and concave receptacles of oil in the rind.

The pulp of the fruit is sourish, somewhat aromatic, and not disagreeable to the taste. The rind is shining, and of a pale yellow colour, and abounds in a very grateful volatile oil. This may be obtained either by expression or distillation. In the former case, it preserves the agreeable flavour of the rind, but is somewhat turbid; in the latter, it is limpid but less sweet. The mode of procuring it by expression is exactly that used for the oil of lemons. (See *Oleum Limonis*.) It is brought from the South of France, Italy, and Portugal.

The oil of bergamot, often called *essence of bergamot*, has a sweet, very agreeable odour, a bitter aromatic pungent taste, and a pale-greenish yellow colour. Its sp. gr. is 0.885, and its composition the same as that of the oil of lemons. Though possessed of the excitant properties of the volatile oils in general, it is employed chiefly if not exclusively as a perfume.

OLEUM BUBULUM. *U. S.*

Neats-foot Oil.

“The oil prepared from the bones of *Bos domesticus*.” *U. S.*

Huile de pied de bœuf, Fr.; Ochsenfussfett, Germ.

Neats-foot oil is obtained by boiling in water for a long time the feet of the ox, previously deprived of their hoof. The fat and oil which rise to the surface are removed, and introduced into a fresh portion of water heated nearly to the boiling point. The impurities having subsided, the oil is drawn off, and if required to be very pure, is again introduced into water, which is kept for twenty-four hours sufficiently warm to enable the fat which is mixed with the oil to separate from it. The liquid being then allowed to

cool, the fat concretes, and the oil is removed and strained, or filtered through layers of small fragments of charcoal free from powder.

This oil is yellowish, and when properly prepared, inodorous and of a bland taste. It thickens or congeals with great difficulty, and is therefore very useful for greasing machinery in order to prevent friction.

It was introduced into the official catalogue of the United States Pharmacopœia as an ingredient of the ointment of nitrate of mercury.

OLEUM CAJUPUTI. U. S. Secondary.

Cajuput Oil.

“The volatile oil of the leaves of *Melaleuca Cajuputi*.” U. S.

Off. Syn. CAJUPUTI. *Melaleuca minor*. *Oleum è foliis destillatum*. *Lond.*; CAJUPUTI OLEUM. Volatile oil of the leaves of *Melaleuca minor*. *Ed.*; MELALEUCA LEUCADENDRON. *Oleum volatile Cajuputi*. *Dub.*

Huile de cajéput, Fr.; *Kajeputöl, Germ.*; *Olio di cajuput, Ital.*; *Kayuputieh, Malay.*

MELALEUCA. *Sex. Syst.* Polyadelphia Icosandria.—*Nat. Ord.* Myrtaceæ.

Gen. Ch. *Calyx* five-parted, semi-superior. *Corolla* five-petaled. *Stamens* about forty-five, very long, conjoined in five bodies. *Style* single. *Capsule* three-celled. *Seeds* numerous. *Roxburgh.*

It was long supposed that the oil of cajuput was derived from the *Melaleuca leucadendron*; but from specimens of the plant affording it, sent from the Moluccas and cultivated in the botanical garden of Calcutta, it appears to be a distinct species, upon which the trivial name of *Cajuputi* has been conferred. It corresponds with the *arbor alba minor* of Rumphius, and is a smaller plant than the *M. leucadendron*. It is possible, however, that the oil may be obtained from different species of *Melaleuca*; as M. Stickel, of Jena, succeeded in procuring from the leaves of the *M. hypericifolia*, cultivated in the botanical garden of that place, a specimen of oil not distinguishable from the cajuput oil of commerce, except by a paler green colour. (*Annal. der Pharm.* xix. 224.)

Melaleuca Cajuputi. Rumphius, *Herbar. Amboinense*, tom. ii. tab. 17; Roxburgh, *Trans. Lond. Med. Bot. Soc.*, A. D. 1829; *Journ. of the Phil. Col. of Pharm.*, vol. i. p. 193.—*Melaleuca minor*. De Candolle. This is a small tree, with an erect but crooked stem, and scattered branches, the slender twigs of which droop like those of the weeping willow. The bark is of a whitish-ash colour, very thick, soft, spongy, and lamellated, throwing off its exterior layer from time to time in flakes, like the birch tree. The leaves have short footstalks; are alternate, lanceolate, when young sericeous, when full grown smooth, deep green, three and five-nerved, slightly falcate, entire, from three to five inches long, from one-half to three-quarters of an inch broad; and when bruised exhale a strong aromatic odour. The flowers, which are small, white, inodorous, and sessile, are disposed in terminal and axillary downy spikes, with solitary, lanceolate, three-flowered bracts. The filaments are three or four times longer than the petals, and both are inserted in the rim of the calyx.

This species of *Melaleuca* is a native of the Moluccas, and other neighbouring islands. The oil is obtained from the leaves by distillation. It is prepared chiefly in Amboyna and Bouro, and is exported from the East Indies in glass bottles. The small proportion yielded by the leaves, and the extensive use made of it in India, render it very costly.

Properties. Cajuput oil is very fluid, transparent, of a fine green colour, a lively and penetrating odour analogous to that of camphor and cardamom, and a warm pungent taste. It is very volatile and inflammable, burning without any residue. The sp. gr. has been variously stated from 0·914 to 0·980. Dr. Thomson says it varies from 0·914 to 0·9274. The oil is wholly soluble in alcohol. When it is distilled a light colourless liquid first comes over, and afterwards a green and denser one. The green colour has been ascribed to the presence of a salt of copper derived from the vessels in which the distillation is performed, and Guibourt obtained two grains and a half of oxide of copper from a pound of the commercial oil. But neither Brande nor Gærtner could detect copper in specimens which they examined; and M. Lesson, who witnessed the process for preparing the oil at Bourgo, attributes its colour to chlorophylle, or some analogous principle, and states that it is rendered colourless by rectification. Guibourt, moreover, obtained a green oil by distilling the leaves of a *Melaleuca* cultivated at Paris. A fair inference is that the oil of cajuput is naturally green; but that, as found in commerce, it sometimes contains copper, either accidentally present, or added with a view of imitating or maintaining the fine colour natural to the oil. The proportion of copper, however, is not so great as to interfere with the internal use of the oil; and the metal may be readily separated by distillation with water, or agitation with a solution of ferrocyanuret of potassium. (*Guibourt.*)

The high price of cajuput oil has led to its occasional adulteration. The oil of rosemary, or that of turpentine, impregnated with camphor and coloured with the resin of milfoil, is said to be employed for the purpose.

Medical Properties and Uses. This oil is highly stimulant, producing when swallowed a sense of heat, with an increased fulness and frequency of pulse, and exciting in some instances profuse perspiration. It is very highly esteemed by the Malays and other people of the East, who consider it a universal panacea. (Lesson, *Journ. de Chim. Med.*, 1827.) They are said to employ it with great success in epilepsy and palsy. (*Ainslie.*) The complaints to which it is best adapted are probably chronic rheumatism, and spasmodic affections of the stomach and bowels, unconnected with inflammation. It has been highly extolled as a remedy in spasmodic cholera, and has been used also as a diffusible stimulant in low fevers. Diluted with an equal proportion of olive oil, it is applied externally to relieve gouty and rheumatic pains. Like most other highly stimulating essential oils, it relieves toothache, if introduced into the hollow of the carious tooth. It is little used in the United States. The dose is from one to five drops, given in emulsion, or upon a lump of sugar. W.

OLEUM CARYOPHYLLI. U.S.

Oil of Cloves.

“The volatile oil of the unexpanded flowers of *Caryophyllus aromaticus.*” *U. S.*

Off. Syn. CARYOPHYLLI OLEUM. *Caryophyllus aromaticus.* *Oleum è floribus, destillatum.* *Lond.*; CARYOPHYLLI OLEUM. Volatile oil of the undeveloped flowers of *Caryophyllus aromaticus.* *Ed.*; EUGENIA CARYOPHYLLATA. *Oleum volatile.* *Dub.*

Huile de girofle, Fr.; *Nelkenöl, Germ.*; *Olio di garofani, Ital.*; *Acceyte de clavos, Span.*
See CARYOPHYLLUS.

This oil is obtained by distilling cloves with water, to which it is cus-

tomary to add common salt, in order to raise the temperature of ebullition; and the water should be repeatedly distilled from the same cloves, in order completely to exhaust them. The product of good cloves is said to be about one-fifth or one-sixth of their weight. The oil was formerly brought from Holland or the East Indies; but since the introduction of the Cayenne cloves into our markets, the reduced price and superior freshness of the drug have rendered the distillation of oil of cloves profitable in this country; and the best now sold is of domestic extraction. We have been informed that from seven to nine pounds of cloves yield to our distillers about one pound of the oil.

Properties. Oil of cloves, when recently distilled, is very fluid, clear, and colourless, but becomes yellowish by exposure, and ultimately reddish-brown. It has the odour of cloves, and a hot, acrid, aromatic taste. Its sp. gr. is variously stated at from 1.034 to 1.061, the latter being given by Bonastre as the sp. gr. of the rectified oil. It is one of the least volatile of the essential oils, and requires for congelation a temperature from zero of Fahrenheit to -4° . It is completely soluble in alcohol, ether, and strong acetic acid. Nitric acid changes its colour to a deep red, and converts it by the aid of heat into oxalic acid. When long kept it deposits a crystalline *stearoptene*. It is frequently adulterated with fixed oils, and sometimes also with oil of pimento and with copaiba. When pure it always sinks in distilled water.

According to Ettling, the oil of cloves consists of two distinct oils, one lighter, the other heavier than water. They may be obtained separate by distilling the oil from a solution of potassa. The lighter comes over, the heavier remains combined with potassa, from which it may be separated by adding sulphuric acid and again distilling. *Light oil of cloves* is colourless, has the sp. gr. 0.918, and consists exclusively of carbon and hydrogen, being isomeric with pure oil of turpentine. It is said not to possess active properties. (*Kane*.) *Heavy oil of cloves* is colourless at first, but darkens with age, has the odour and taste of cloves, is of the sp. gr. 1.079, boils at 470° , and forms soluble and crystallizable salts with the alkalies. Hence it has been called *eugenic* or *caryophyllic acid*. It consists of carbon, hydrogen, and oxygen; the formula, according to Ettling, being $C_{24}H_{15}O_5$.

Medical Properties and Uses. Its medical effects are similar to those of cloves, and it is used for the same purposes; but its most common employment is as a corrigent of other medicines. Like other powerful irritants, it is sometimes effectual in relieving toothache, when introduced into the cavity of a carious tooth. The dose is from two to six drops.

Haile de cannelle, *Fr.*; Zimmtöl, *Germ.*; Olio di cannella, *Ital.*; Aceyte de canela, *Span.*

See CINNAMOMUM.

The United States Pharmacopœia includes, under the name of *Oil of*

Cinnamon, both the oil procured from the Ceylon cinnamon, and that from the Chinese cinnamon or cassia. As these oils, though very different in price, and slightly in flavour, have the same medical properties, are used for the same purposes, are often sold by the same name, and are not unfrequently mixed together, there does not seem to be sufficient ground for maintaining any official distinction between them. Nevertheless, the Edinburgh College has given them distinct places in its official list, designating the one as oil of cinnamon and the other as oil of cassia.

Oil of Cinnamon of Ceylon, is prepared in that island from the inferior kinds of cinnamon which are of insufficient value to pay the export duty. The following account of the method of extraction, as formerly practised, is given by Marshall. The bark, having been coarsely powdered, is macerated for two days in sea-water, and then submitted to distillation. A light and a heavy oil come over with the water, the former of which separates in a few hours, and swims upon the surface, the latter falls to the bottom of the receiver, and continues to be precipitated for ten or twelve days. In future distillations the saturated cinnamon water is employed in connexion with sea-water to macerate the cinnamon. Eighty pounds of the bark, freshly prepared, yield about two and a half ounces of the lighter oil, and five and a half of the heavier. From the same quantity of cinnamon which has been kept for several years in store, about half an ounce less of each oil is obtained. The two kinds are probably united in the oil of commerce.

Recently prepared oil of cinnamon is of a light yellow colour, which becomes deeper by age, and ultimately red. Dr. Pereira states that the London druggists redistil the red oil, and thus obtain two pale yellow oils, one lighter and the other heavier than water, with a loss of about ten per cent. in the process. The oil has the flavour of cinnamon in a concentrated state. When applied undiluted to the tongue it is excessively hot and pungent. Dr. Duncan states that it sometimes has a peppery taste, which he ascribes to an admixture of the leaves with the bark in the preparation of the oil.

Chinese oil of cinnamon (*oil of cassia*) is imported from Canton and Singapore. Like the former variety it has a pale yellow colour, which becomes red with age; at least such is the case with the specimens which have come under our observation. Its flavour is similar to that of oil of cinnamon, though inferior; and it commands a much smaller price. The following remarks apply to both oils.

Oil of cinnamon is heavier than water, having the sp. gr. of about 1.035. Alcohol completely dissolves it; and, as it does not rise in any considerable quantity at the boiling temperature of that liquid, it may be obtained by forming a tincture of cinnamon and distilling off the menstruum. When exposed to the air, it absorbs oxygen, and is said to be slowly converted into a peculiar acid denominated *cinnamic* or *cinnamonic* acid, two distinct resins, and water. *Cinnamic acid* is colourless, crystalline, of a sourish taste, volatilizable, slightly soluble in water, readily dissolved by alcohol, and convertible by nitric acid with heat into benzoic acid. It is sometimes seen in crystals in bottles of the oil which have been long kept. Of the two resins, one is soluble both in hot and cold alcohol, the other readily in the former, but sparingly in the latter. Oil of cinnamon is almost wholly converted by nitric acid slowly added to it into a crystalline mass, which is supposed to be a compound of the oil and acid. The researches of Dumas and Péligot have led to the opinion that there exists in the oil a compound radical, named *cinnamule*, consisting of carbon, hydrogen, and oxygen ($C_{16}H_7O_2$), which unites with one equivalent of hydrogen to form oil of cinnamon, and one equivalent of oxygen to form anhydrous

cinnamic acid. Crystallized cinnamic acid contains in addition one equivalent of water. The oil of cinnamon is said to be frequently adulterated with alcohol and fixed oil.

Medical Properties and Uses. It has the cordial and carminative properties of cinnamon, without its astringency; and is much employed as an adjuvant to other medicines, the taste of which it corrects or conceals, while it conciliates the stomach. As a powerful local stimulant, it is sometimes prescribed in gastrodynia, flatulent colic, and langour from gastric debility. The dose is one or two drops, and may be most conveniently administered in the form of emulsion.

OLEUM CUBEBAE. *U. S.*, *Ed.*

“The volatile oil of the berries of *Piper Cubeba*.” *U. S.*

See CUBEBA.

This oil is obtained from the fruit of *Piper Cubeba*, by grinding it, and then distilling with water. From ten pounds of cubebs Schönwald procured eleven ounces of oil, and this result very nearly coincides with the experiments of Christison, who obtained seven per cent. When perfectly pure, the oil is colourless; but as usually found, is yellowish or greenish. It has the smell of cubebs, and a warm, aromatic, camphorous taste; is of a consistence approaching that of almond oil, is lighter than water, having the sp. gr. 0.929; and, when exposed to the air, is said to thicken without losing its odour. Upon standing, it sometimes deposits crystals, which are thought to be a hydrate of the oil. It consists of carbon and hydrogen, and its formula is stated to be $C_{15}H_{12}$.

The oil has all the medicinal properties of cubebs, and may often be advantageously substituted for the powder, in the commencing dose of ten or twelve drops, to be gradually increased until its effects are obtained, or until it proves offensive to the stomach. It may be given suspended in water by means of sugar, or in the form of emulsion, or enclosed in capsules of gelatin. W.

OLEUM LIMONIS. *U. S.*

Oil of Lemons.

“The volatile oil of the rind of the fruit of *Citrus Limonum*.” *U. S.*

Off. Syn. LIMONUM OLEUM. *Citrus Limonum. Oleum è Fructus Cortice exteriori destillatum. Lond.*; LIMONUM OLEUM. Volatile oil of the rind of the fruit of *Citrus medica. Ed.*; CITRUS MEDICA. Fructus tunicæ exterioris oleum volatile. *Dub.*

Huile de citron, *Fr.*; Cetroneöl, *Germ.*; Olio di limone, *Ital.*; Aceyte de limon, *Span.*
See LIMON.

The exterior rind of the lemon abounds in an essential oil, which, as it is contained in distinct cellules, may be separated by simple expression. The rind is first grated from the fruit, and then submitted to pressure in a bag of fine cloth. The oil thus obtained is allowed to stand till it becomes clear, when it is decanted, and preserved in stopped bottles. By a similar process, that delightful perfume, the *essence of bergamot*, is procured from the fruit of the bergamot citrus; and the oil called by the French *huile de cedrat*, from the citron. (See *Oleum Bergamii* and *Limon*.) All these oils may also be obtained by distillation; but thus procured, though clearer, and in

consequence of the absence of mucilage, less liable to change on keeping, they have less of the peculiar flavour of the fruit, and the mode by expression is generally preferred. They are all brought originally from Italy, Portugal, or the South of France.

Properties. The oil of lemons is a very volatile fluid, having the odour of the fruit, and a warm, pungent, aromatic taste. As ordinarily procured it is yellow, and has the specific gravity 0·8517; but by distillation it is rendered colourless; and, if three-fifths only are distilled, its sp. gr. is reduced to 0·847, at 71° F. It is soluble in all proportions in anhydrous alcohol. When perfectly pure, it consists exclusively of carbon and hydrogen, and is said to be identical in composition with pure oil of turpentine, or camphene; its formula being $C_{10}H_8$. In this state it is capable of absorbing almost half its weight of muriatic acid gas, by which it is converted into a crystalline substance, and a yellow oily fuming liquid. The crystals are analogous to the artificial camphor which results from the action of muriatic acid upon the oil of turpentine, and are a compound of the oil and acid. The oil of lemons is said to consist of two isomeric oils.

The oil of lemons is often adulterated by the fixed oils and by alcohol, the former of which may be detected by the permanent stain which they impart to paper, the latter by the milkiness produced by the addition of water.

Medical Properties and Uses. This oil has the stimulant properties of the aromatics; but is chiefly used to impart a pleasant flavour to other medicines. It has recently been lauded as an application to the eye in certain cases of ophthalmia.

OLEUM LINI. *U. S., Dub.*

Flaxseed Oil.

“The oil of the seeds of *Linum usitatissimum*.” *U. S.*

Off. Syn. LINI OLEUM. *Linum usitatissimum. Oleum è Seminibus expressum. Lond.*; Expressed oil of the seeds of *Linum usitatissimum. Ed.*

Linseed oil; Huile de lin, *Fr.*; Leinöl, *Germ.*; Olio di lino, *Ital.*; Aceyte de linaza, *Span.*

See LINUM.

This oil is obtained by expression from the seeds of the *Linum usitatissimum*, or common flax. In its preparation on a large scale, the seeds are usually roasted before being submitted to pressure, in order to destroy the gummy matter contained in their exterior coating. The oil is thus obtained more free from mucilage, but more highly coloured and more acid than that procured by cold expression. Flaxseed oil is of a yellowish-brown colour, a disagreeable odour, and nauseous taste; is of the sp. gr. 0·932; boils at 600° F.; does not congeal at zero; dissolves in forty parts of cold and five of boiling alcohol, and in one part and a half of ether (*Christison's Dispensatory*); becomes rancid with facility; and has the property of drying or becoming solid on exposure to the air. On account of its drying property, it is highly useful in painting, and the formation of printers' ink.

Medical Properties and Uses. It is laxative in the dose of a fluidounce, but on account of its disagreeable taste is seldom given internally. It is

sometimes added to purgative enemata; but its most common application is externally to burns, usually in combination with lime-water.

OLEUM MYRISTICÆ. *U. S.*

Oil of Nutmeg.

“The volatile oil of the kernels of *Myristica moschata*.” *U. S.*

Off. Syn. MYRISTICÆ OLEUM. *Myristica moschata. Oleum è nucleis destillatum. Lond.*; MYRISTICÆ OLEUM. Volatile oil of the kernels of the fruit of *Myristica officinalis. Ed.*; MYRISTICA MOSCHATA. *Oleum volatile. Dub.*

See MYRISTICA.

This oil is obtained from powdered nutmegs by distillation with water. It is colourless or of a pale straw-colour, limpid, lighter than water, soluble in alcohol and ether, with a pungent spicy taste, and a strong smell of nutmeg. It consists of two oils, which may be separated by agitation with water, one rising to the surface, the other sinking to the bottom. Upon standing it deposits a crystalline stearoptene, which is called by John *myristicin*. It may be used for the same purposes as nutmeg, in the dose of two or three drops; but is not often employed. W.

OLEA. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Oleaceæ.

Gen. Ch. *Corolla* four-cleft, with subovate segments. *Drupe* one-seeded. *Willd.*

Olea Europæa. *Willd. Sp. Plant.* i. 44; *Woodv. Med. Bot.* p. 280. t. 98. This valuable tree is usually from fifteen to twenty feet in height, though it sometimes attains a much greater size, particularly in Greece and the Levant. It has a solid, erect, unequal stem, with numerous straight branches, covered with a grayish bark. The leaves, which stand opposite to each other on short footstalks, are evergreen, firm, lanceolate, entire, two or three inches in length, with the edges somewhat reverted, smooth and of a dull green colour on their upper surface, whitish and almost silvery beneath. The flowers are small, whitish, and disposed in opposite axillary clusters, which are about half as long as the leaves, and accompanied with small, obtuse, hoary bractes. The fruit or olive is a smooth, oval drupe, of a greenish, whitish, or violet colour, with a fleshy pericarp, and a very hard nut of a similar shape. The flowers are not very fruitful, as clusters containing not less than thirty yield only two or three ripe olives.

The olive tree, though believed by some to have been originally from the Levant, flourishes at present in all the countries bordering on the Mediterranean, and has been cultivated from time immemorial in Spain, the South of France, and Italy. It begins to bear fruit after the second year, is in full

bearing at six years, and continues to flourish for a century. There are several varieties, distinguished by the form of the leaves, and the shape, colour, and size of the fruit. The variety *longifolia* of Willdenow is said to be chiefly cultivated in Italy and the South of France, and the variety *latifolia* in Spain. The latter bears much larger fruit than the former; but the oil is less esteemed.

The leaves and bark of the olive tree have an acrid and bitterish taste, and have been employed as substitutes for cinchona, though with no great success. In hot countries, a substance resembling the gum-resins exudes spontaneously from the bark. It was thought by the ancients to possess useful medicinal properties, but is not now employed. Analyzed by Pelletier, it was found to contain resinous matter, a small quantity of benzoic acid, and a peculiar principle analogous to gum, which has received the name of *olivile*. But the fruit is by far the most useful product of the tree. In the unripe state it is hard and insupportably acrid; but when macerated in water, or an alkaline solution, and afterwards introduced into a solution of common salt, it loses these properties, and becomes a pleasant and highly esteemed article of diet. The pericarp, or fleshy part of the ripe olive, abounds in a fixed oil, which constitutes its greatest value, and for which the tree is chiefly cultivated in the South of Europe. The oil is obtained by first bruising the olives in a mill, and then submitting them to pressure. The product varies much, according to the state of the fruit and the circumstances of the process. The best oil, called *virgin oil*, is obtained from the fruit picked before it has arrived at perfect maturity, and immediately pressed. It is distinguished by its greenish hue. The common oil used for culinary purposes, and in the manufacture of the finest soaps, is procured from very ripe olives, or from the pulp of those which have yielded the virgin oil. In the latter case, the pulp is thrown into boiling water, and the oil removed as it rises to the surface. An inferior kind, employed in the arts, especially in the preparation of the coarser soaps, plasters, unguents, &c., is afforded by fruit which has been thrown into heaps and allowed to ferment for several days, or by the *marc* left after the expression of the finer kinds of oil, broken up, exposed to the fermenting process, and again introduced into the press.

Olive oil is imported in glass bottles, or in flasks surrounded by a peculiar kind of net-work made of grass, and usually called Florence flasks. The best comes from the South of France, where most care is exercised in the selection of the fruit.

Properties. The pure oil is an unctuous liquid, of a pale yellow or greenish-yellow colour, with scarcely any smell, and a bland slightly sweetish taste. Its sp. gr. is 0.9153. It is soluble in twice its volume of ether, but is only partially soluble in alcohol, at least unless this liquid be in very large proportion. It begins to congeal at 38° F. At a freezing temperature a part of it becomes solid, and the remainder retaining the liquid consistence, may be separated by pressure, or by the agency of cold alcohol, which dissolves it. The concrete portion has been found by MM. Pelouze and Boudet to be a definite compound of margarin and olein; the liquid portion is uncombined olein. According to Braconnot, the oil contains 72 parts of olein, and 28 of margarin in the hundred. Olive oil is solidified by nitrous acid and by nitrate of mercury, and converted into a peculiar fatty substance, which has received the name of *elaïdin*. The olein of all oils which have not the drying property undergoes the same change, when acted on by nitrous acid; and the singular fact is stated by MM. Pelouze and Boudet, that the margarin of olive oil, combined as it is with olein, is converted by

that acid into elaidin, while the same principle in a state of purity is not affected by it. (*Journ. de Pharm.* xxiv. 391.)

Olive oil when exposed to the air is apt to become rancid, acquiring a disagreeable smell, a sharp taste, a thicker consistence, and a deeper colour; and the change is promoted by heat. It is said to be frequently adulterated with the cheaper fixed oils, especially with that of poppies; but the adulteration may easily be detected by reducing the temperature to the freezing point. As other oils are less readily congealed than the olive oil, the degree of its purity will be indicated by the degree of concretion. Another mode has been indicated by M. Poutet, founded on the property possessed by the supernitrate of mercury of solidifying the oil of olives, without a similar influence upon the other oils. Six parts of mercury are dissolved at a low temperature in seven parts and a half of nitric acid of the sp. gr. 1.35; and this solution is mixed with the suspected oil in the proportion of one part to twelve, the mixture being occasionally shaken. If the oil is pure, it is converted after some hours into a yellow solid mass; if it contain a minute proportion, even so small as a twentieth of poppy oil, the resulting mass is much less firm; and a tenth prevents a greater degree of consistence than oils usually acquire when they concreate by cold.

Medical Properties and Uses. Olive oil is nutritious and mildly laxative, and is occasionally given in cases of irritable intestines, when the patient objects to more disagreeable medicines. Taken into the stomach in large quantities, it serves to involve acrid and poisonous substances, and mitigate their action. It has also been recommended as a remedy for worms, and is a very common ingredient in laxative enemata. Externally applied, it is useful in relaxing the skin, and sheathing irritated surfaces from the action of the air; and is much employed as a vehicle or diluent of more active substances. In the countries bordering on the Mediterranean, it is thought, when smeared over the skin, to afford some protection against the plague; and applied warm, by means of friction over the surface, is said to be useful as a remedy in the early stages of that complaint. But the most extensive use of olive oil is in pharmacy, as a constituent of liniments, ointments, cerates, and plasters.

The dose as a laxative is from one to two fluidounces.

Ricinus communis. *Willd. Sp. Plant.* iv. 564; *Woodv. Med. Bot.* p. 624. t. 221. The castor oil plant, or *palma Christi*, attains in the East Indies and Africa the character of a tree, and rises sometimes thirty or forty feet in height. In the temperate latitudes of North America and Europe it is an annual plant; though it is stated by M. Achille Richard, that in the South

of France, in the vicinity of Nice, on the sea-coast, he saw a small wood consisting entirely of this species of *Ricinus*. The following description applies to the plant as cultivated in cool latitudes. The stem is of vigorous growth, erect, round, hollow, smooth, glaucous, somewhat purplish towards the top, branching, and from three to eight feet or more in height. The leaves are alternate; peltate or supported upon footstalks inserted into their lower disk; palmate, with seven or nine pointed serrate lobes; smooth on both sides; and of a bluish-green colour. The flowers are monœcious, stand upon jointed peduncles, and form a pyramidal terminal raceme, of which the lower portion is occupied by the male flowers, the upper by the female. Both are destitute of corolla. In the male flowers the calyx is divided into five oval, concave, pointed, reflected, purplish segments, and encloses numerous stamens, which are united into fasciculi at their base. In the female, the calyx has three or five narrow lanceolate segments; and the ovary, which is roundish and three-sided, supports three linear, reddish stigmas, forked at their apex. The fruit is a roundish glaucous capsule, with three projecting sides, covered with tough spines, and divided into three cells, each containing one seed, which is expelled by the bursting of the capsule.

This species of *Ricinus* is a native of the East Indies and Northern Africa; has become naturalized in the West Indies; and is cultivated in various parts of the world, in no country perhaps more largely than in the United States. New Jersey, Virginia, North Carolina, and the States upon the right bank of the Ohio, are the sections in which it is most abundant. The flowers appear in July, and the seeds ripen successively in August and September. The part employed in medicine is the fixed oil extracted from the seeds.

1. **THE SEEDS.** These are about as large as a small bean, oval, compressed, obtuse at the extremities, very smooth and shining, and of a grayish or ash colour, marbled with reddish-brown spots and veins. At one end of the seed is a small yellowish tubercle, from which an obscure longitudinal ridge proceeds to the opposite extremity, dividing the sides upon which it is situated into two flattish surfaces. In its general appearance the seed is thought to resemble the insect called the *tick*, the Latin name of which has been adopted as the generic title of the plant. Its variegated colour depends upon a very thin pellicle, closely investing a hard, brittle, blackish, tasteless, easily separable shell, within which is the kernel, highly oleaginous, of a white colour, and a sweetish taste succeeded by a slight degree of acrimony. The seeds easily become rancid, and are then unfit for the extraction of the oil, which is acrid and irritating. In 100 parts of the seeds Geiger found, exclusive of moisture, 23·82 parts of envelope, and 69·09 of kernel. These 69·09 parts contained 46·19 of fixed oil, 2·40 of gum, 20·00 of starch and lignin, and 0·50 of albumen.

Taken internally the seeds are powerfully cathartic, and often emetic. Two or three are sufficient to purge, and seven or eight act with great violence. This property depends upon an acrid principle, which has by some been thought to exist exclusively in the integuments, by others in the embryo. But it is now satisfactorily ascertained that the integuments are inert; and Guibourt maintains that the principle alluded to pervades the whole kernel, in connexion with the oil. This principle is volatile, and dissipated by the heat of boiling water. By a much greater heat the oil itself becomes altered, and acquires acrid properties.

2. **THE OIL.** This may be extracted from the seeds in three ways; 1. by decoction, 2. by expression, and 3. by the agency of alcohol.

The process by decoction, which is practised in the East and West In-

dies, consists in bruising the seeds previously deprived of their husk, and then boiling them in water. The oil, rising to the surface, is skimmed or strained off, and afterwards again boiled with a small quantity of water to dissipate the acrid principle. To increase the product it is said that the seeds are sometimes roasted. The oil is thus rendered brownish and acrid; and the same result takes place in the second boiling, if care is not taken to suspend the process soon after the water has been evaporated. Hence it happens that the West India oil has generally a brownish colour, an acrid taste, and irritating properties.

The oil is obtained, in this country, by expression. The following, as we have been informed, are the outlines of the process usually employed by those who prepare it on a large scale. The seeds having been thoroughly cleansed from the dust and fragments of the capsules with which they are mixed, are conveyed into a shallow iron reservoir, where they are submitted to a gentle heat insufficient to scorch or decompose them, and not greater than can be readily borne by the hand. The object of this step is to render the oil sufficiently liquid for easy expression. The seeds are then introduced into a powerful screw press. A whitish oily liquid is thus obtained, which is transferred to clean iron boilers, supplied with a considerable quantity of water. The mixture is boiled for some time, and, the impurities being skimmed off as they rise to the surface, a clear oil is at length left upon the top of the water, the mucilage and starch having been dissolved by this liquid, and the albumen coagulated by the heat. The latter ingredient forms a whitish layer between the oil and the water. The clear oil is now carefully removed; and the process is completed by boiling it with a minute proportion of water, and continuing the application of heat till aqueous vapour ceases to rise, and till a small portion of the liquid taken out in a vial, preserves a perfect transparency when it cools. The effect of this last operation is to clarify the oil, and to render it less irritating by driving off the acrid volatile matter. But much care is requisite not to push the heat too far, as the oil then acquires a brownish hue, and an acrid peppery taste, similar to those of the West India medicine. After the completion of the process, the oil is put into barrels, and thus sent into the market. There is reason, however, to believe that much of the American oil is prepared by merely allowing it to stand for some time after expression, and then drawing off the supernatant liquid. One bushel of good seeds yields five or six quarts, or about twenty-five per cent. of the best oil. If not very carefully prepared, it is apt to deposit a sediment upon standing; and the apothecary frequently finds it necessary to filter it through coarse paper before dispensing it. Perhaps this may be owing to the plan just alluded to of purifying the oil by rest and decantation.* We have been told that the oil in barrels occasionally deposits a copious whitish sediment in cold weather,

* We find the following sentence in Christison's Dispensatory, p. 793. "If the statement made above, on the authority of Boutron-Charlard, be correct [that no margarins is deposited by castor oil previously heated to 212°], this circumstance [the deposition of a crystalline matter by castor oil in cold weather], instead of being an objection, is strong proof of the American oil being really cold drawn, and not prepared by dry heat and ebullition, as Drs. Wood and Bache have represented." If it be intended here to throw discredit on our statement, we have only to reply, that we have ourselves witnessed the arrangements above described, and had the account of the steps of the process from the manufacturers, as it was at the time conducted in this city. That American castor oil is also prepared by mere expression, rest, and decantation, we have stated in the text. We are disposed to give the preference to that prepared by the former process, as freer from impurities, and therefore likely to keep better, and as milder in its action in consequence of the volatilization of a portion of the acrid principle.

which it redissolves when the temperature rises. This substance is probably margarin, or an analogous principle. A large proportion of the drug consumed in the eastern section of the Union is derived, by way of New Orleans, from Illinois and the neighbouring States, where it is so abundant that it is sometimes used for burning in lamps.

The process for obtaining castor oil by means of alcohol has been practised in France, but the product is said to become rancid more speedily than that procured in the ordinary mode.

Properties. Pure castor oil is a thick, viscid, colourless fluid, with little or no odour, and a mild though somewhat nauseous taste, followed by a slight sense of acrimony. As found in the shops it is often tinged with yellow, and has an unpleasant smell; and parcels are sometimes though rarely met with, of a brownish colour, and hot acrid taste. It does not readily congeal by cold. When exposed to the air it slowly thickens, without becoming opaque, and it ranks among the drying oils. It is heavier than most of the other fixed oils, from which it differs also in being soluble in all proportions in cold absolute alcohol. Weaker alcohol, of the sp. gr. 0.8425, takes up about three-fifths of its weight. Adulterations with other fixed oils may thus be detected, as the latter are much less soluble in this fluid. Such adulterations, however, are seldom if ever practised in this country. Castor oil is also soluble in sulphuric ether. Its proximate composition is but imperfectly understood. When distilled it yields, according to MM. Bussy and Lecanu, 1. a colourless, highly odorous volatile oil, which crystallizes by cold, 2. two oleaginous acids, denominated ricinic and ricin-oleic, which are excessively acrid and nearly concrete, and 3. a solid spongy residue, amounting to two-thirds of the oil employed. Supposing these acids to be developed by heat, we can readily account for the injurious influence of too high a temperature in the preparation of the oil. By the action of nitrous acid, it is converted into a peculiar oleaginous body called *palmin*, which yields *palmic acid* and glycerin when saponified. Alkalies unite with castor oil forming soaps, and determine the formation of three acids, the *ricinic*, *ricin-oleic*, and *ricino-stearic acids*, which can be obtained separate. Hence it has been inferred that the oil consists of three principles, for which the names of *ricin*, *ricin-olein*, and *ricino-stearin* have been proposed. (*Kane's Chemistry*.) These principles, however, have not been isolated. The purgative property of the oil is supposed by MM. Bussy and Lecanu to be essentially attached to the oil itself, and not to reside in any distinct principle which it may hold in solution.

Castor oil which is acrid to the taste may be rendered mild by boiling it with a small proportion of water. If turbid, it should be clarified by filtration through paper. On exposure to the air, it is apt to become rancid, and is then unfit for use.

Medical Properties and Uses. Good castor oil is a mild cathartic, speedy in its action, usually operating with little griping or uneasiness, and evacuating the contents of the bowels without much increasing the alvine secretions. Hence it is particularly applicable to cases of constipation from collections of indurated feces, and to those cases in which acrid substances have been swallowed, or acrid secretions have accumulated in the bowels. From its mildness it is also especially adapted to diseases attended with irritation or inflammation of the bowels, as colic, diarrhœa, dysentery, and enteritis. It is habitually resorted to in the cases of pregnant and puerperal women; and is decidedly, as a general rule, the best and safest cathartic for children. Infants usually require a larger relative dose than adults, probably because they digest a larger proportion of the oil.

The dose for an adult is about a fluidounce, for an infant from one to three or four fluidrachms. It is sometimes of exceedingly difficult administration, not so much from any peculiarly disagreeable taste, as from the recollection of former nausea, or other uneasiness which it may have produced, and from its clamminess and unpleasant adhesiveness to the mouth. In a few cases the disgust which it excites is utterly unconquerable by any effort of resolution. It is desirable, therefore, to obviate this inconvenience as far as possible by the mode of exhibition. A common method is to give it floating on the surface of mint or cinnamon water; but that which we have found upon the whole the least offensive, is to mix it with a cup of hot sweetened coffee, by which it is rendered more fluid, and its taste considerably disguised. Some take it in wine or spirituous liquors; but these are generally contraindicated in the cases to which the medicine is applicable. When the stomach is unusually delicate, the oil may be made into an emulsion with mucilage or the yolk of an egg, loaf sugar, and some aromatic water. To the mixture laudanum may be added in cases of intestinal irritation. Castor oil may also be beneficially used as an enema in the quantity of two or three fluidounces mixed with some mucilaginous liquid.

Though apt to become rancid by itself, it loses much of this susceptibility when mixed with lard; and some apothecaries are said to use it as a substitute for olive oil in unguents and cerates. But the slightly irritating properties of even the mildest castor oil, render it inapplicable in those preparations which are intended rather to alleviate irritation than to produce it.

OLEUM ROSÆ. U.S.

Oil of Roses.

“The volatile oil of *Rosa centifolia*.” U. S.

Off. Syn. ROSÆ OLEUM. Volatile oil of the petals of *Rosa centifolia*. *Ed.*

See ROSA CENTIFOLIA.

This is commonly called *attar*, *otto*, or *essence of roses*. It is prepared on a large scale in Egypt, Persia, Cashmere, India, and other countries of the East, by distilling the petals of the rose with water. The oil concretes and floats upon the surface of the water when it cools. The precise species of rose from which the oil is extracted is not in all instances certainly known; but it is said to be obtained from the *R. damascena* in Northern India, and the *R. moschata* in Persia. It is furnished in very minute proportion; not more than three drachms having been obtained by Colonel Polier, in Hindostan, from one hundred pounds of the petals. It is usually imported in small bottles, and is very costly.

Oil of roses is nearly colourless, or presents some shade of green, yellow, or red; but, according to Polier, the colour is no criterion of its value. It is concrete below 80°, and becomes liquid between 84° and 86°. Its odour is very powerful and diffusive. At 90° its sp. gr. is 0.832. Alcohol dissolves it, though not freely when cold. It consists of two oils, one liquid, the other concrete at ordinary temperatures. These may be separated by freezing the oil, and compressing it between folds of blotting paper, which absorbs the liquid oil or eleoptene and leaves the concrete or stearoptene. The latter consists exclusively of carbon and hydrogen, the former of these and oxygen.

Sandal-wood oil, other volatile oils, fixed oils, spermaceti, &c., are said

to be added as adulterations. The volatile additions may be detected by not being concrete; the fixed, by the greasy stain left on paper, when heated.

Oil of roses may be added, as a very grateful perfume, to various spirituous preparations for internal use, and to cerates and ointments. W.

OLEUM SESAMI. *U.S. Secondary.*

Benne Oil.

Huile volatile de térébenthine, Fr.; Terbinthinöl, Germ.; Olio della trementina, Ital.; Aceyte de trementina, Span.

See TEREBINTHINA.

This is commonly called *spirits* or *spirit* of turpentine. It is prepared by distillation from our common turpentine, though equally afforded by other varieties. It may be distilled either with or without water; but in the latter case a much higher temperature is required, and the product is liable to be empyreumatic. To obtain it absolutely pure it should be redistilled from a solution of caustic potassa. The Dublin College gives the following formula for its preparation. “Take of common turpentine, [*Terebinthina Vulgaris*, *Lond.*] five pounds; water, four pints. Draw off the oil in a copper alembic.” But it is at present never prepared by the apothecary, and in all the other Pharmacopœias is placed in the catalogue of the *Materia Medica*. The turpentine of the *Pinus palustris* is said to yield about seventeen per cent. of oil; while the common turpentine of Europe affords twenty-four per cent. Large quantities of the oil are distilled in North Carolina for exportation.

Pure oil of turpentine is perfectly limpid and colourless, of a strong, penetrating, peculiar odour, and a hot, pungent, bitterish taste. It is much lighter than water, having the specific gravity 0.86 at 72° F.; is highly volatile and inflammable; boils at a temperature somewhat higher than 300°; is very slightly soluble in water, less soluble in alcohol than most other volatile oils, and readily soluble in sulphuric ether. Boiling alcohol dissolves it with facility, but deposits most of the oil upon cooling. One hundred parts of alcohol of 0.84, dissolve 13.5 parts of the oil at 72°. As found in commerce, it always contains oxygen; but when perfectly pure, it consists exclusively of carbon and hydrogen, and is thought to be isomeric with the radical of camphor. Hence it has been denominated camphene. (*See page 155.*) According to Blanchet and Sell, it consists of two distinct isomeric oils, which, by the absorption of oxygen, are converted into two distinct resins, corresponding to those found by Unverdorben in colophony. (*Journ. de Pharm. xx. 226.*) But there is reason to believe that these oils are the

results of chemical reaction; as, when isolated, they have boiling points higher than that of the original oil. The oil of turpentine absorbs muriatic acid, forming with it two compounds, one a red dense liquid, the other a white crystalline substance resembling camphor, and hence called *artificial camphor*. The latter consists of the unaltered oil (camphene) combined with the acid, and is therefore muriate of camphene. In the former the oil appears to have undergone some molecular change, being converted into an oil isomeric with the oil of turpentine, but differing from it in its action on polarized light, and in forming a liquid compound with muriatic acid. If the muriate of camphene be distilled with lime, the acid is retained, and an oil comes over, differing from pure oil of turpentine, in having no action on polarized light, and from the oil just mentioned in forming a solid compound with muriatic acid. These three oils are said to be isomeric. (*Soubeiran and Capitaine, Journ. de Pharm.* xxvi. 11.) Nitric acid converts the oil of turpentine into resin, and, by long boiling, into *turpentinic acid*. On exposure to the air and light, turpentine deposits a white solid matter in acicular crystals, which are without taste or smell, insoluble in cold water, but soluble in ether and alcohol. (*Boissenot, Journ. de Chim. Med.* ii. 143.) White crystals of stearoptene, heavier than water and fusible at 20° , separate from the oil at the temperature of 18° below zero. These are probably a hydrate of the oil.

Exposed to the air the oil absorbs oxygen, becomes thicker and yellowish, and loses much of its activity, owing to the formation of resin. Hence the British Colleges direct a process for its rectification, consisting in distilling it with about four measures of water. But the process is difficult, in consequence of the great inflammability of the vapour, and its rapid formation, which causes the liquid to boil over. In this country it is scarcely necessary, as the recent oil can be obtained at an expense less than that which would be incurred by its redistillation on a small scale. Another mode of purifying the oil is to agitate it with one-eighth of alcohol, which dissolves the portion that has become resinous by the absorption of oxygen. About one-fifth of the alcohol is retained by the oil, but is readily separated by agitation with water.

Medical Properties and Uses. Oil of turpentine is stimulant, diuretic, occasionally diaphoretic, anthelmintic, in large doses cathartic, and externally rubefacient. When swallowed in moderate quantities it produces a sense of warmth in the stomach, accelerates the circulation, and increases the heat of the skin, without especially affecting the functions of the brain. In small doses, frequently repeated, it stimulates the kidneys, augmenting the secretion of urine, and often producing, especially if long continued, painful irritation of the urinary passages, amounting sometimes to violent strangury. At the same time it imparts the odour of violets to the urine; and this effect is also produced by its external application, or even by breathing the air of an apartment impregnated with its vapours. In large doses it occasions slight vertigo, or a sense of fulness in the head, sometimes amounting to intoxication, attended frequently with nausea, and succeeded generally, though not always, by speedy and brisk catharsis. When this effect is experienced, the oil is carried out of the bowels, and, no time being allowed for absorption, is less apt to irritate the kidneys and bladder than when taken in small and repeated doses. In some constitutions it produces, even when taken internally, an erythematic eruption on the skin.

The oil is employed in numerous diseases. As a stimulant it is useful in low forms of fever, particularly in cases where there is reason to sus-

pect ulcerations of the mucous membranes. There is a particular state of fever usually attended with much danger, in which we have found this remedy uniformly successful. The condition of things alluded to, is one which occurs in the latter stages of typhoid fevers or lingering remittents, in which the tongue, having begun to throw off its load of fur in patches, has suddenly ceased to clean itself, and become dry and brownish. The skin is at the same time dry, the bowels torpid and distended with flatus, and the patient sometimes affected with slight delirium. Under the use of small doses of oil of turpentine frequently repeated, the tongue becomes moist and again coated, the tympanitic state of the bowels disappears, and the patient goes on to recover as in a favourable case of fever. We are disposed to ascribe the effect to a healthy change produced by the oil in the ulcerated surface of the intestines. The medicine has also been recommended as a counter-irritant in yellow and puerperal fevers; and may undoubtedly be given with advantage in the latter stages of these diseases, and in other instances of gastric and enteritic inflammations, which require a resort to stimulation; but the highly favourable reports which have been made of its effects in the early stages of puerperal peritonitis, have probably originated in the confounding of intestinal irritation with that formidable disease. In chronic rheumatism, particularly sciatica and lumbago, the oil has often been given with great benefit. It has also been much extolled as a remedy in neuralgia, in epilepsy and tetanus, in passive hemorrhages, particularly from the bowels, in disordered conditions of the alimentary canal attended with sallow countenance, foul tongue, tumid abdomen, sour or fetid eructation, and general depravation of health, in obstructions of the bowels, in some forms of chronic dysentery and diarrhœa, in obstinate gleets and leucorrhœa, in suppression of urine, and in chronic nephritic and calculous affections. We have seen it very beneficial in hæmoptysis. As a vermifuge also it is very highly esteemed, especially in cases of tænia. It appears, by its poisonous operation, to destroy or debilitate the worm, which losing its hold upon the bowels is then easily discharged. In cases of worms in the stomach it is often very useful. The worms, in this instance, are destroyed and digested as any other dead animal matter. In dropsies with feeble action, the oil may sometimes be advantageously given as a diuretic; and in amenorrhœa from torpor of the uterine vessels it is occasionally useful. As a local stimulant or carminative it may be given beneficially in some instances of flatulent colic, and gout in the stomach.

The dose for ordinary purposes is from five to thirty drops, repeated every hour or two in acute, and three or four times a day in chronic diseases. In rheumatism it is recommended by some in the dose of a fluidrachm every four hours. As a remedy for the tape-worm it is given in the quantity of one or two fluidounces, and should be followed by castor oil if it do not operate in three or four hours. It has also proved successful in tænia in the dose of half a drachm twice a day continued for a considerable time. In ordinary cases of worms, the usual dose may be given. It may be administered dropped on sugar, or in emulsion with gum Arabic, loaf sugar, and cinnamon or mint water.

In the form of enema, it has been employed in amenorrhœa, and is highly useful in cases of ascarides, obstinate constipation, and distension of the bowels from accumulation of air. No remedy is more effectual in tympanites than injections of the oil of turpentine. From half a fluidounce to two fluidounces may be administered in this way, suspended by the yolk of eggs in half a pint or a pint of water or some mucilaginous fluid.

Externally applied, the oil of turpentine irritates and speedily inflames

the skin; and in low forms of fever, with coldness of the surface, is when heated one of the most efficacious rubefacients. It is also used as a liniment in rheumatic and paralytic affections, and various internal inflammations. It should generally, in mild cases, be diluted with olive oil; and in some constitutions, even in this state, produces such violent inflammation of the skin, with extensive eruptions, as to render its external use in any shape improper. Mixed with some mild oil and introduced on cotton into the ear, it is sometimes beneficial in deafness arising from a deficient or unhealthy secretion of wax. Applied to recent burns it is thought by some to be highly useful in allaying the burning pain and promoting a disposition to heal. For this purpose, however, it is usually mixed with the resin cerate (*basilicon ointment*), so as to form a liniment capable of being spread upon linen rags. (See *Linimentum Terebinthinæ*.)*

CROTON. See CASCARILLA.

Croton Tiglium. Willd. *Sp. Plant.* iv. 543; Woodv. *Med. Bot.* 3d ed. vol. 5. p. 71. This species of *Croton* is a small tree or shrub, with a few spreading branches, bearing alternate petiolate leaves, which are ovate, acuminate, serrate, smooth, of a dark green colour on the upper surface, paler beneath, and furnished with two glands at the base. The flowers are in erect terminal racemes, scarcely as long as the leaf—the lower being female, the upper male, with straw-coloured petals. The fruit is a smooth capsule, about the size of a filbert, with three cells, each containing a single seed.

The tree is a native of Hindostan, Ceylon, the Moluccas, and other parts of continental and insular India. It is pervaded throughout by an acrid purgative principle, which is probably analogous to that found in other plants belonging to the family of the Euphorbiaceæ. Rumphius says that the root is employed in Amboyna in the dose of a few grains as a drastic purge in dropsy; and, according to the same author, the leaves are so acrid that, when chewed and swallowed, they excite painful inflammation in the lips, mouth, throat, and along the whole course of the alimentary canal. The wood is said in small doses to be diaphoretic, in larger, purgative and emetic. But the seeds are the portion in which the active principle of the plant is most concentrated. These have been long employed throughout the whole of India as a powerful purgative, and were introduced so early as the year

* The following is the formula adopted by the Philadelphia College of Pharmacy for the preparation of the rubefacient liniment, so much sold under the name of *British Oil*. R. Olei Terebinth. fʒviiij, Olei Lini fʒviiij, Olei Succini fʒiv, Olei Juniperi fʒiv, Petrolei Barbados. fʒiij, Petrolei American. (Seneca oil) fʒj. Misce. (*Journ. of the Phil. Col. of Pharm.* v. 29.)

1630 into Europe, where they were known by the names of *Grana Molucca* and *Grana Tiglia*. But in consequence of their violent effects they passed into neglect, and had ceased to be ranked among medicinal substances, when at a recent period attention was again called to them by the writings of some English physicians in India. They are now imported for the oil which they afford, and which is the only portion of the plant considered official.

These seeds are rather larger than a grain of coffee, of an oblong form, rounded at the extremities, with two faces, the external considerably more convex than the internal, separated from each other by longitudinal ridges, and each divided by a similar longitudinal ridge, so that the whole seed presents an irregular quadrangular figure. Sometimes, as in the grain of coffee, their internal surface is flat with a longitudinal groove, owing to the presence of only two seeds in the capsule, the groove being produced by the central column or axis. The shell is covered with a soft yellowish-brown epidermis, beneath which the surface is black and smooth; and as the epidermis is often partially removed by friction during their carriage, the seeds as they come to us are frequently of a mottled appearance, and sometimes nearly black. The kernel or nucleus is of a yellowish-brown colour, and abounds in oil. In India the seeds are prepared for use by submitting them to slight torrefaction, by which the shell is rendered more easily separable. In the dose of one or two grains the kernel purges with great activity.

The oil is obtained by expression from the seeds, previously deprived of the shell. It may also be separated by decoction in water, or by the action of ether, which dissolves the oil, and leaves it behind when evaporated. According to Dr. Nimmo, the seeds consist of 64 parts of kernel, and 36 of envelope, in the hundred; and the cotyledons yield 60 per cent. of oil. They yielded to Brandes, upon analysis, independently of the shell, traces of a volatile oil, fixed oil, a peculiar fatty acid called *crotonic acid*, an alkaloid which he called *crotonin*, resin, stearin, wax, extractive, sugar, starch, gum, albumen, gluten, lignin, and salts. Some doubts are entertained as to the existence of crotonin. The *crotonic acid* is the most interesting ingredient, is thought to be the active principle of the seeds, and is separated along with the oil in expression. It may be obtained by treating the oil with solution of potassa, decomposing the resulting soap by tartaric acid, filtering and distilling the solution, neutralizing the product with baryta water, evaporating to dryness, decomposing the salt of baryta with strong phosphoric acid, and again distilling. (*Christison's Dispensatory*.) The acid solidifies at 23° F., is highly volatile, has a very acrid taste, is very irritating to the nostrils, and forms salts with alkaline bases called crotonates. It is this principle probably which causes the dust and exhalation from the croton seeds sometimes to excite excessive irritation in the mucous surfaces of those who prepare them for expression, or otherwise work among them.

Properties. Croton oil, as found in the shops, is often of an orange or reddish-yellow colour, which is owing to the roasting of the seeds previously to expression, or to their having been kept too long. When procured without roasting from fresh seeds, it is yellowish or nearly colourless. Its smell is faint but peculiar, its taste hot and acrid, leaving in the mouth a disagreeable sensation which continues for many hours. The oil is wholly soluble in sulphuric ether and oil of turpentine, and partially so in alcohol. According to Dr. Nimmo, it consists of two portions, one acrid and purgative, amounting to forty-five per cent., soluble in cold alcohol, and having an acid reaction, the other a mild oleaginous substance like olive oil, soluble in ether and the oil of turpentine, and very slightly soluble in hot alcohol, by

which it is deposited when the liquor cools. The acrid portion probably consists of a resinous substance, and the acrid volatile acid, before mentioned, by the name of *crotonic acid*.

It is thought that croton oil is often adulterated with other fixed oils. The Edinburgh College gives the following test of its purity. "When agitated with its own volume of pure alcohol and gently heated, it separates on standing, without having undergone any apparent diminution." This, however, does not agree with the statement of Dr. Nimmo.

We have been told by Dr. M. Burrough, who was for some time in India, that much of the oil there prepared for exportation, under the name of croton oil, is derived from the seeds of a plant wholly different from the *Croton Tiglium*. Dr. R. E. Griffith informed us that, from a parcel of these seeds presented to him by Dr. Burrough, he had succeeded in producing a plant which proved to be the *Jatropha Curcas*, the seeds of which are known by the name of *Barbadoes nuts*. (See *Tapioca*.) This oil is weaker than the genuine croton oil, but is said by Dr. Burrough to be an efficient cathartic in the dose of three or four drops. It is stated by Dr. Hamilton that croton seeds are afforded by the *Croton Pavana*, growing in Ava and the Eastern parts of Bengal; and it is highly probable that a portion of the croton oil of commerce is obtained from these seeds. (*Trans. Lin. Soc.*, xiv. 257.)

Medical Properties and Uses. The substance under consideration is a powerful hydragogue purgative, acting, for the most part, when administered in moderate doses, with ease to the patient; but in large doses apt to excite vomiting and severe griping pain, and capable, if immoderately taken, of producing fatal effects. It acts with very great rapidity, frequently evacuating the bowels in less than an hour, and generally exciting a rumbling sensation in half that period. It possesses also a great advantage in the minuteness of the dose, on account of which it may frequently be given when we should fail with more bulky medicines, as in mania, coma, and the cases of children. A drop placed on the tongue of a person in a comatose state will generally operate. Though long used in India, and known a century ago to the Dutch physicians, it did not attract general notice till about 1820, when it was introduced into England by Mr. Conwell. It is chiefly employed in cases of obstinate constipation, in which it often produces the happiest effects after the failure of other medicines; but it may also be advantageously employed in almost all cases in which powerful and speedy purging is demanded. Dropsy, apoplexy, mania, and visceral obstructions, are among the complaints in which it has been particularly recommended. It has recently been employed with great asserted benefit in neuralgia, epilepsy, and spasm of the glottis, and has been supposed to have powers in these affections, independent of its purgative property. The seeds are said to have been used with great success in India in amenorrhœa. Applied externally, the oil produces inflammation of the skin attended with a pustular eruption, and has been used in this way in rheumatism, gout, neuralgia, glandular and other indolent swellings, and in pulmonary diseases. It should be diluted with three parts of olive oil, soap-liniment, oil of turpentine, or other convenient vehicle, and applied in the way of liniment twice or oftener in the twenty-four hours. Sometimes the insusceptibility of the skin to its influence is such as to require its application undiluted. For further information on this subject the reader is referred to the *Amer. Journ. of Med. Sciences*, xv. 240. The oil may be also applied externally, in the form of a plaster, made by incorporating one part of it with four parts of lead plaster melted by a very gentle heat.

The dose for an adult is one or two drops, and is most conveniently ad-

ministered in the form of pill. A very safe and convenient plan is to make two drops into four pills with crumb of bread, and give one every hour till they operate. The oil may also be given in emulsion. The form of tincture may be advantageously resorted to when a minute quantity of the medicine is required, as it affords the means of readily dividing the dose. It is said that four drops of the oil, applied externally by friction around the umbilicus, will produce a purgative effect. (*Dict. des Drogues.*) W.

OLIBANUM. *Lond., Dub.*

Olibanum.

“*Boswellia serrata. Gummi-resina.*” *Lond., Dub.*

Encens, Fr.; Weihrauch, Germ.; Olibano, Ital.; Olibano, Incienso, Span.; Koondir Zuckir, Hindoo.; Cundur Looban, Arab.

Olibanum, the *frankincense* of the ancients, was erroneously ascribed by Linnæus to the *Juniperus Lycia*. There appear to be two varieties of olibanum, one derived from the countries bordering on the Red Sea, and taken to Europe by way of the Mediterranean, the other brought directly from Calcutta. The origin of the former remains yet undecided; though some writers refer it to a species of *Amyris*. The latter has been satisfactorily ascertained to be the product of the *Boswellia serrata* of Roxburgh, a large tree growing in the mountains of India, and found by Mr. Colebrook abundant in the vicinity of Nagpur. The tree belongs to the class and order *Decandria Monogynia*, and to the natural order *Terebintaceæ* of Kunth.

The Arabian or African frankincense is in the form of yellowish tears and irregular reddish lumps or fragments. The tears are generally small, oblong or roundish, not very brittle, with a dull and waxy fracture, softening in the mouth, and bearing much resemblance to mastich, from which, however, they differ in their want of transparency. The reddish masses soften in the hand, have a stronger smell and taste than the tears, and are often mixed with fragments of bark, and small crystals of carbonate of lime.

The Indian frankincense, or olibanum, consists chiefly of yellowish, somewhat translucent, roundish tears, larger than those of the African, and generally covered with a whitish powder produced by friction. It has a balsamic resinous smell, and an acrid, bitterish, and somewhat aromatic taste. When chewed it softens in the mouth, adheres to the teeth, and partially dissolves in the saliva, which it renders milky. It burns with a brilliant flame, and a fragrant odour. Triturated with water it forms a milky imperfect solution. Alcohol dissolves nearly three-fourths of it, and the tincture is transparent. From 100 parts, Braconnot obtained 8 parts of volatile oil, 56 of resin, 30 of gum, and 5.2 of a glutinous matter insoluble in water or alcohol, with 0.8 loss. Various saline substances were found in its ashes. The oil may be separated by distillation, and resembles that of lemons in colour and smell.

Medical Properties and Uses. Olibanum is stimulant like the other gum-resins; but is now never used internally. It is chiefly employed for fumigations, and enters into the composition of some unofficinal plasters. W.

PAPAVER. *Sex. Syst.* Polyandria Monogynia.—*Nat. Ord.* Papaveraceæ.

Gen. Ch. Corolla four-petaled. Calyx two-leaved. Capsule one-celled, opening by pores under the persistent stigma. *Willd.*

Opium is at present generally believed to be derived exclusively from the *Papaver somniferum*, though every species of poppy is capable of yielding it to a greater or less extent, and some authors have indicated the *Papaver orientale* as its real source. The British and French Pharmacopœias unite with our own in recognising only the first mentioned species.

Papaver somniferum. Willd. *Sp. Plant.* ii. 1147; Woodv. *Med. Bot.* p. 376. t. 138. There are two varieties of this species, which are distinguished by the titles of the white and black poppy, derived from the colour of their seeds. It is the former which is usually described as the proper opium plant. The *white poppy* is an annual plant, with a round, smooth, erect, glaucous, often branching stem, rising two or three feet in height, and sometimes attaining five or even six feet in favourable situations. The leaves are large, variously lobed and toothed, and alternately disposed upon the stem which they closely embrace. The flowers are terminal, very large, and of a white or silver gray colour. In India they appear in February, in Europe and the United States, not earlier than June, July, or August. The calyx is smooth, and composed of two leaves, which fall when the petals expand. These are usually four in number; but there is a variety in which the flower is double. The germen, which is smooth and globular, supports a radiated stigma, and is surrounded by numerous short and slender filaments, with erect, oblong, compressed anthers. The capsule is smooth and glaucous, of a rounded shape, from two to four inches in diameter, somewhat flattened at the top and bottom, and crowned with the persistent stigma, the diverging segments of which are arranged in a circle upon the summit. It contains numerous minute white seeds, which, when perfectly ripe, escape through small openings beneath the stigma. In the *black poppy*, the flower, though sometimes white, is usually violet coloured or red, the capsule is somewhat smaller and more globular, and the seeds are of a brown or blackish colour.

All parts of the poppy are said to contain a white opaque narcotic juice; but the leaves, when analyzed by M. Blondeau yielded none of those active principles by which opium is characterized. (*Journ. de Pharm.* vii. 214.) It is in the capsule that the juice most abounds, and the virtues of the plant chiefly reside. Hence this part is sometimes employed medicinally in Europe, where it is considered officinal. (See *Papaveris Capsulæ*.) The seeds are wholly destitute of narcotic properties, and are even used as food in many parts of the world. The Romans employed them in the preparation of various dainties. They abound with a bland oil, which may be extracted by expression, and has most of the useful properties of olive oil. It is

an article of much importance on the continent of Europe, particularly in France, in the northern departments of which the black poppy is very extensively cultivated for the seed alone. The oil is employed for culinary and pharmaceutic purposes, in painting, and the manufacture of soap, and in other ways as a substitute for olive oil, which is said to be frequently adulterated with it. The poppy does not appear to elaborate the milky fluid in which its narcotic properties reside, before a certain period of its growth; for we are told that in Persia, the young plants which are pulled up to prevent too thick a crop, are used as pot-herbs; and the *μηχαν* of the Greeks, which is believed to be identical with the *Papaver somniferum*, is said by Hippocrates to be nutritive.

Though generally believed to be a native of Asia, this species of poppy grows wild in the South of Europe, and even in England, whither its seeds are supposed to have been brought at a very early period. It was cultivated by the ancient Greeks, and is mentioned by Homer as a garden plant. It is at present cultivated very extensively in India, Persia, Egypt, and Asiatic Turkey, for the opium which it affords; and in several parts of Europe, especially in France, not only for this product, but also for the seed and capsules. In this country it is found only in our gardens as an ornamental flower.

The process for procuring opium from the poppy, as practised by the modern inhabitants of India and Persia, according to the reports of Kerr and of Kœmpfer, is very nearly the same with that described by Dioscorides as employed in his own times, about eighteen hundred years since; and the accounts of Belon, Olivier, and Texier, as to the modes of collection in Asia Minor, are not materially different. As the capsules abound most in the narcotic juice, it is from these that the opium is procured. According to Texier, a few days after the fall of the flower, men and women proceed to the fields, and make horizontal incisions in the capsule, taking care not to penetrate its cavity. A white juice exudes, and appears in the form of tears upon the edges of the incisions. The field is left in this state for twenty-four hours, after which the juice is scraped off by means of large blunt knives. A portion of the epidermis of the capsule is also removed, and constitutes about one-twelfth of the whole product. Each poppy-head affords opium but once. Thus collected, the opium is in the state of an adhesive and granular jelly. It is placed in small earthen vessels, where it is beaten and at the same time moistened with saliva. When of a proper consistence, it is wrapped in leaves and sent into the market. (*Journ. de Pharm.* xxi. 196.) Considerable quantities of good opium have been obtained by different individuals in England by scarifying the capsules of the poppy.* Similar success has been met with in France; and the drug obtained by incisions in both countries has been found nearly if not quite equal to that imported from the East. In the *Dictionnaire des Drogues* it is even stated, that a specimen of opium collected in this way in the vicinity of Provins, gave sixteen per cent. of the active principle,

* So early as the year 1796, a premium was awarded by the society for the encouragement of arts, to Mr. Ball, for a specimen of British opium; and in 1823, Messrs. Cowley and Stains collected 196 pounds, which sold for nearly seven dollars a pound, from little more than twelve acres of land. This product, however, was by no means equal to that obtained in Scotland by Mr. John Young. From one acre of ground planted with poppies and potatoes, he procured fifty-six pounds of opium, valued at 450 dollars, while the whole expense was more than repaid by the potatoes, and the oil expressed from the seeds. For papers on the subject of the cultivation of the poppy in England, see *Edin. Philosoph. Journ.* vol. i. p. 253, and the *Quarterly Journal of Science*, vol. iv. p. 69.

while a good commercial specimen examined by M. Petit, afforded only eight per cent.

Another method of extracting the virtues of the capsules, is to select such as have ceased to yield their juice by exudation, to beat them with a small proportion of water, and inspissate the liquid thus obtained by artificial heat. The ancient Greeks were acquainted with both processes, as appears from the writings of Dioscorides. The term *οπιον*, derived from *οπος*, juice, they applied to the substance procured by incision, and answering precisely to the modern opium. The inspissated expressed juice they called *μηχανιον*, from *μηχαν*, the name of the plant. Tournefort states that it is the latter preparation which is exported from Turkey as opium, the former being much more valuable, and therefore retained in the country for the use of the great and wealthy. This error has been copied by many writers on the *Materia Medica*; and till within a comparatively few years, opium was generally believed to be an extract obtained by evaporating either the expressed juice, or a decoction of the capsules.

Commercial History. Commerce is supplied with opium chiefly from Hindostan, Persia, Egypt, and the Asiatic dominions of Turkey. Immense quantities are produced in the Indian provinces of Bahar and Benares, and in the more interior province of Malwa. The opium of Hindostan is distributed extensively through continental and insular India, where it is habitually employed in the place of spirituous liquors. Great quantities are also sent to China, into which it finds an easy entrance, notwithstanding prohibitory laws. Much was formerly imported by the East India Company into England, through which a small portion reached our own country; but at present India opium is considered so far inferior to that from Turkey, that it has been almost entirely excluded from our market, and none is brought directly from the East. The great demand for it in the Indian Archipelago and in China, and its consequent high price, have probably contributed more even than its reputed inferiority to this result. Indeed, Ainslie explicitly states that India opium is inferior to none; and it is probable that the specimens from which the description was drawn up that has been current among authors upon the *Materia Medica*, were the refuse of the Eastern market. We know that the drug was formerly very much and variously adulterated by the natives. Among the impurities mentioned by authors are the extract of the poppy procured by decoction, the powdered leaves and stems of the plant made into a paste with mucilage, the oil of sesamum, catechu, and even cow-dung. But a more careful superintendence by the officers of the Company is said to have resulted in a great improvement of the India opium. Of that produced in Persia, very little is brought to this country; and it is scarcely known in our markets as a distinct variety. Much was formerly produced in Upper Egypt, especially in the district of ancient Thebes, which was supposed to yield it in greatest perfection. It was in fact for a long time generally known by the name of *Opium Thebaicum*, and laudanum is still frequently directed in prescriptions as the *Tinctura Thebaica*. Its cultivation has recently been again introduced into Egypt; and considerable quantities are now annually exported.

Turkey opium is produced in Anatolia, and is shipped chiefly from the port of Smyrna. It is brought to the United States, either directly from the Levant, or indirectly through the Mediterranean ports of France. From the treasury returns for the year 1829, it appears that the value of opium imported from the Turkish dominions was 92,924 dollars, from France on the Mediterranean, 12,187 dollars, and from all other parts of the

world only 2,040 dollars. None was imported from India. Turkey opium usually comes to us in masses of irregular size and shape, generally more or less flattened, covered with leaves, or the remains of leaves, and with the reddish capsules of some species of *Rumex*, which are said to be absent in the inferior kinds, and may therefore be considered as affording some indication of the purity of the drug. We may account for this circumstance upon the very probable supposition, that these capsules are removed during the operation which the masses sometimes undergo in the hands of the merchants, after leaving those of the cultivators. We are told by the French writers, that extensive frauds are practised at Marseilles in this branch of commerce. The opium brought thither from the Levant is first softened, and then adulterated with various matters, which are incorporated in its substance. To use a strong expression of M. Guibourt, they make the opium over again at Marseilles. Our traders to the Mediterranean would do well to bear this assertion in mind. According to Dr. A. T. Thomson, one-fourth part of Turkey opium generally consists of impurities. Sand, ashes, the seeds of different plants, the extracts of the poppy, *Lactuca virosa*, *Glycyrrhiza glabra*, and *Chelidonium glaucum*, gum Arabic, tragacanth, aloes, even small stones, and minute pieces of lead and iron, are mentioned among the substances employed in the sophistication of the drug. In England a sophisticated opium has been prepared, so nearly resembling good Turkey opium in appearance, that by the eye alone it would be difficult to detect the fraud, and yet wholly destitute of the active principle of this drug. Portions of it have been sent into the markets both of France and this country. It is probably the genuine drug, deprived of its morphia by some process which does not materially disturb the visible arrangement of its particles.* (*Am. Journ. of Pharm.* x. 261.)

* The great importance of opium renders it desirable that all its commercial varieties should be accurately described, and their relative value so far as possible ascertained. The following statement has been drawn up from the most recent published accounts of this drug, and from the personal observations of the author. The papers of Guibourt in France, Christison in Great Britain, and Merck and Martius in Germany, have been consulted. (See *Journ. de Pharm.* xvii. 714, and xxi. 542; and *Annalen der Pharm.* xviii. 79, and xxiv. 56.)

The varieties of this drug may be arranged, according to the countries in which they are produced, under the heads of *Turkey*, *Egyptian*, *India*, and *Persia* opium.

I. TURKEY OPIUM. This title belongs to the opium produced in the Turkish province of Anatolia, and exported from Smyrna and Constantinople. According to some authorities, there is no essential difference between the parcels of the drug brought from these two ports. Others maintain that they are distinct varieties, differing in their interior structure, and probably also in the precise place of their production, and the mode of their collection. The truth probably is, that most of the opium shipped at Constantinople is produced in the northern parts of Anatolia, while that from Smyrna is collected in the provinces more convenient to the latter city; and, though it is possible that an identical drug may be occasionally brought from the two ports, yet there seems to be good ground in general for arranging it under different varieties, as derived from these different sources.

1. Smyrna Opium. This is the variety which is beyond all comparison most abundant in our markets; and it is from this that the ordinary descriptions of opium are drawn up. It comes to us in masses of various size, usually from half a pound or somewhat less to a pound in weight, sometimes, though rarely, as much as two or even three pounds, originally perhaps of a globular form, but variously indented, and rendered quite irregular in shape, by the pressure to which they are subjected, while yet soft, in the cases which contain them. Sometimes they are even pressed out into flat cakes. As brought into market, the lumps are usually hard on the outside, but still soft within. They are covered externally with the remains of leaves, and with the reddish capsules of a species of *Rumex*, which have no doubt been applied in order to prevent the surfaces from adhering. Not-

Opium is regarded as inferior when it is of a blackish colour; a weak or empyreumatic smell; a sweet or slightly nauseous and bitter taste; a soft, viscid, or greasy consistence; a dull fracture; or an irregular, heterogeneous texture, arising from the intermixture of foreign substances. It should not

withstanding, however, this coating, the masses sometimes stick together, and two or more become consolidated into one. In this way the fact may be accounted for, that the seeds of the *Rumex* are occasionally found in the interior of the masses. In the finer parcels of Smyrna opium, the colour internally is light brown; in the inferior it is darker. A peculiar character of this variety is, that when a lump of it is cut into and then carefully torn, numerous minute shining tears are observable, particularly under a microscope, bearing some resemblance to small seeds, but readily distinguishable by pressure between the fingers. They are undoubtedly formed from the drops of juice which escape from the incisions in the capsules, and which, according to Bélon, are allowed to concreate before they are removed. From the account of the same author it appears that, after the juice has been collected, it is not subjected to the process of kneading or beating, as in the case of other varieties of opium; so that the tears preserve their original shape in the mass. It is probably owing to the peculiar mode of collecting Smyrna opium, that minute pieces of the skin of the poppy capsules are found intermingled in the mass, these being separated in the process of removing the adhering tears. In the finer specimens of Smyrna opium, these fragments of the capsules are the only impurities. This variety of the drug is of very different qualities, the finest kinds yielding, according to Merck, as much as 13 per cent. of pure morphia, while from some very bad parcels he could not procure more than 3 or 4 per cent. In these inferior specimens the colour is darker, the smell is often musty, and there is very generally more or less mouldiness both upon the surface, and in the interior of the masses, indicating perhaps too much moisture in the opium originally, or its subsequent exposure to an injurious degree of dampness. Good Smyrna opium ought to yield 10 or 11 per cent. of morphia.

2. *Constantinople Opium.* Most of the Constantinople opium is in lumps from half a pound to two and a half pounds in weight, and scarcely distinguishable in exterior appearance from those of the former variety, being equally irregular in shape, and in like manner covered with the capsules of the *Rumex*. It differs, however, strikingly from the Smyrna opium in its interior constitution, being, according to Merck, wholly destitute of the tears which characterize that variety. This would indicate some difference in the mode of collecting and preparing the juice. In the case of the Constantinople opium, it is probably either removed from the capsules before concretion, or subjected to pressure afterwards. Merck says that he has not discovered in this variety those minute portions of the poppy capsules which are usually present in the Smyrna opium. The average quality of the Constantinople opium, as above described, is about equal to that of the drug from Smyrna; but it appears to be occasionally purer; as Merck obtained from one specimen as much as 15 per cent. of pure morphia. Notwithstanding what has been above stated, we are not yet in possession of facts to prove that this is not, as some have supposed it to be, the better sort of Smyrna opium selected and sent to the capital.

Guibourt describes another variety of Constantinople opium of much inferior character. "It comes," he observes, "in small flattened cakes, sufficiently regular and of a lenticular shape, from two to two and a half inches in diameter, and always covered with a poppy leaf, the midrib of which divides the surface into two equal parts. It has an odour similar to that of the preceding variety, but feebler, and it blackens and dries in the air. It is more mucilaginous than Smyrna opium, and contains only half as much morphia." These characters are obviously those of Egyptian opium; and, though the parcels which came under the notice of Guibourt may have been imported directly from Constantinople, it is highly probable that they were originally from Alexandria. Mr. Stettner of Trieste, though well acquainted with the opium commerce of that port, admits no such Constantinople opium as that described by Guibourt. (*Annal. der Pharm.* xxiv. 65.)

II. *EGYPTIAN OPIUM.* This is in flat roundish cakes, of various dimensions, sometimes as much as six inches in diameter and a pound in weight, usually, however, much smaller, and sometimes not weighing more than half an ounce. These cakes are either wrapped in a poppy leaf, so placed that the midrib divides the surface into two equal parts, or exhibit vestiges of such a covering. Occasionally the brown colour of the opium is seen through the leaf, and the surface appears as if uncovered, while the leaf is still present. This variety of opium is always destitute of the *Rumex* capsules, and differs from the Smyrna opium also in being brittle instead of tenacious, and equally hard in the centre as at the surface of the mass. Its fracture is conchoidal and of a waxen lustre, and

impart a deep brown colour to the saliva, nor leave a dark uniform trace when drawn over paper, nor form with water a thick viscid solution.

Properties. Good opium has a peculiar, strong, narcotic odour, and a bitter, somewhat acrid taste. When long chewed it excites much irritation

small fragments of it are translucent. Its colour is usually redder than that of Smyrna opium, though it is sometimes dark. Some of the pieces, on exposure to the air, become damp and sticky on the outer surface, indicating the fraudulent addition of some deliquescent substance. The odour is similar to that of Smyrna opium, but weaker. There can be little doubt that this opium is, in some way, sophisticated in its preparation; as it yields only 6 or 7 per cent. of morphia. (*Merck*.) A specimen examined by Mr. J. Evans of Philadelphia, yielded only 3.55 per cent. Egyptian opium, therefore, should never be dispensed by the apothecary, or employed in the preparation of his tinctures; as the prescription of the physician is based upon the strength of good Smyrna opium, which is about twice that of the Egyptian.

III. INDIA OPIUM. Little if any of this opium reaches our market. There appear to be two chief varieties of it, one produced in Bahar and Benares, in the Bengal Presidency, and called *Bengal opium*, the other in the interior provinces, and designated by the name of *Malwa opium*.

1. *Bengal Opium.* This appears to be identical with the variety sometimes called *Patna opium*. It is in round balls, weighing three pounds and a half, invested by a coating half an inch thick, composed of agglutinated leaves and poppy-petals. The interior of the mass is of a brownish-black colour, of the consistence of a stiff paste, and possessed in a high degree of the characteristic odour and taste of opium. Mr. Smyttan, inspector of opium at Bombay, obtained from two to three and a half per cent. of morphia from this variety of opium; but, as he obtained only from five to six and a half per cent. from Smyrna opium, we may conclude that the drug was not exhausted by his process, and may estimate the proportion of its active principle at double that stated above. Still, even with this allowance, it must be subjected to great adulteration in its preparation; as it is by no means probable that the poppies cultivated in India yield a product materially weaker than those of Turkey. Yet Christison states, that all the India opium which he has seen is exempt from the mixture of leaves, seeds, and fragments of poppy capsules so abundant in Smyrna opium. Its inferior character is in some degree probably owing to the juice, after collection, being kept for some time before it is made up, and consequently undergoing fermentation.

The India opium examined by Dr. A. T. Thomson was apparently of inferior character. As described by that author, it was in round masses, covered with the petals of the poppy in successive layers, to the thickness of nearly one-fourth of an inch. It had a strong empyreumatic smell, with little of the peculiar heavy odour of Turkey opium. Its taste was more bitter and equally nauseous, but less acrid. Its colour was blacker, and its texture, though as tenacious, was less plastic. It was more friable, and when triturated with water, was wholly suspended or dissolved, leaving none of that plastic residue which is afforded by the other variety. It yielded to Dr. Thomson more narcotina than Turkey opium, but only about one-third the quantity of morphia. All these are the characters of an extract of the poppy heads, rather than of their inspissated juice. The absence of the plastic principle analogous to caoutchouc is strong evidence in favour of this view of its nature; for it is obvious that water would not extract this principle from the capsules, while it is hardly probable that the juice is destitute of it. Besides, the strength indicated by Dr. Thomson is very nearly the same with that of the extract of the capsules prepared in France. The Bengal opium is at present a superior drug to that here described, though still inferior to the Smyrna opium.

There is a variety of Patna or Bengal opium, called *garden Patna opium*, which was described in the last edition of this work, on the authority of Dr. Christison, as Malwa opium. Dr. Christison has subsequently ascertained its true origin. It is prepared in Bahar with peculiar care, from juice which has not been suffered to undergo fermentation. It is in cakes three or four inches square, and about half an inch thick, which are packed in cases with a layer of mica between them. These cakes are without covering, hard, dry, and brittle, of a uniform shining fracture, and not unlike an extract in appearance. The colour is sometimes almost black, and sometimes of a light brown, not unlike that of Egyptian opium. Dr. Christison states that it is much superior to the globular Bengal opium, and that some specimens are little inferior to Turkey opium in the proportion of morphia.

2. *Malwa Opium.* This is in flat, roundish cakes, five or six inches in diameter, and

in the lips and tongue, and even blisters the mouth of those unaccustomed to its use. Its colour is a reddish-brown or deep fawn; its texture compact; its specific gravity 1.336. When drawn over paper it usually leaves an interrupted trace of a light brown colour. It is often soft in the interior of the mass, and in this state is tenacious; but when exposed to the air it gradually hardens, and ultimately becomes brittle, breaking with a shining fracture, and affording when pulverized a yellowish-brown powder, which becomes adhesive upon a slight elevation of temperature. It readily inflames upon the application of a lighted taper. It yields its virtues to water, alcohol, and diluted acids, but not to ether. To all these menstrua it imparts a deep brown colour. Alcohol dissolves about four-fifths of it. Pelletier states that the proportion taken up by water varies in all specimens. He never found the quantity of extract prepared with cold water to exceed 12 parts out of 16. (*Journ. de Pharm.* Nov. 1832.)

Much attention has been devoted to the chemical constitution of opium; and very interesting results have been obtained. It was by their researches into the nature of this substance that chemists were led to the discovery of those vegetable alkaloids, which, as the active principles of the plants in which they are found, have recently attracted so much attention among physicians, and been applied so advantageously in the treatment of disease. To Sertürner, an apothecary at Eimbeck, in Hanover, certainly belongs the credit of having opened this new and most important field of experiment. In the year 1803, M. Derosne made known the existence of a crystallizable substance which he had discovered in opium, and which he erroneously believed to be the active principle. In the following year, Seguin discovered another crystallizable body, which subsequent experience has proved to be the true narcotic principle of opium; but he did not fully investigate its nature, and no immediate practical advantage was derived from his excellent analysis. About the same time, Sertürner was engaged in a similar investigation, the results of which, very analogous to those obtained by Seguin, were published in a German journal, without, however, attracting general attention. In this state the subject remained till the year 1817, when Sertürner announced the existence of a saline compound in opium, consisting of a peculiar alkaline principle united with a peculiar

from four to eight ounces in weight. They are commonly quite hard, dry, and brittle, of a light-brown colour, a shining fracture, a compact homogeneous texture, and free from mechanical impurities. The quality is superior to that of common Bengal opium.—(*Christison's Dispensatory*.)

IV. PERSIA OPIUM. A variety of opium under this name has sometimes existed in the markets of London, and has even found its way to this country, though it is very rare. It is described as being in cylindrical pieces, about three and a half inches long and half an inch thick, wrapped in glossy paper, and tied with a cotton thread. It is of a uniform consistence, but exhibits, nevertheless, under the microscope, small agglutinated tears, much less than those of the Smyrna opium. It has the liver-brown colour of Egyptian opium, a virose, musty odour, and a very bitter taste; and, like Egyptian opium, softens in a moist atmosphere. It is said to have been brought to England from Trebizond on the Black Sea; but its origin is not known. It is of inferior quality. From the report of a trial in the city of New York, published in the *Journal of Commerce*, it appears, that a parcel of Persia opium imported into that city from London in August 1835, was in small round balls, and contained only 3 per cent. of morphia.

It is highly important that the real value of these commercial varieties of opium should be known to the physician and apothecary; as otherwise, there can be no certainty in relation to the strength of the preparations which may be made from them. In the preparation of laudanum and the other tinctures into which opium enters, it is understood that the drug employed should have the average quality of good Smyrna opium. The inferior kinds should be used only for the extraction of morphia.

acid, and clearly demonstrated the precise nature of a substance, which, though before discovered both by Seguin and by himself, had been hitherto but vaguely known. To the alkali, in which he correctly conceived the narcotic powers of the opium to reside, he gave the name of *morphium*, which has been subsequently changed to *morphia* by English writers, in order to render it analogous to the titles of the other alkalies. The acid he called *meconic*, a term derived from the Greek name of the poppy. The correctness of the statements of Sertürner was confirmed by the experiments of Robiquet, who also satisfactorily demonstrated that the substance obtained by Derosne, and called by him *the salt of opium*, was a principle altogether distinct from the morphia, though supposed to possess very considerable influence over the system. In the belief of its narcotic powers, Robiquet denominated it *narcotin*, a title which it still retains. Several other peculiar principles have since been discovered; though it is difficult to resist the impression that some of them may be the result of the processes to which opium is submitted for their extraction. According to the views of its constitution at present admitted, opium contains, 1. morphia; 2. narcotina or narcotin; 3. codeia; 4. paramorphia; 5. narcein; 6. meconin; 7. meconic and sulphuric acids; 8. a peculiar acid, not yet fully investigated; 9. extractive matter; 10. gum; 11. bassorin; 12. a peculiar resinous body insoluble in ether and containing nitrogen; 13. fixed oil; 14. a substance resembling caoutchouc; 15. an odorous volatile principle; besides lignin, and a small proportion of acetic acid, sulphate of lime, sulphate of potassa, alumina, and iron. Besides these principles, Pelletier announced the discovery of another which he called pseudomorphia, but which appears to be only an occasional constituent of opium. (See *Journ. de Pharm.* xxi. 575.)

Of the principles above mentioned *morphia* is by far the most important. It is generally admitted to exist in opium united with meconic acid in the state of meconate, and to a certain extent also as a sulphate. Of morphia and the mode of procuring it, and of its salts, we shall treat at large under another head. (See *Morphia*.)

Narcotina or *narcotin* receives one or the other of these names according as it is considered alkaline or neuter, they who rank it among the alkalies giving it the former, they who deny it such a position, the latter. It exists in opium, chiefly at least in the free state, and is left behind in considerable quantity when the drug is macerated with water. It is white, tasteless, and inodorous; and crystallizes in silky flexible needles, usually larger than the crystals of morphia, fusible at a moderate elevation of temperature, insoluble in cold water, soluble in 400 parts of boiling water, in 100 parts of cold and 24 of boiling alcohol which deposits it upon cooling, and very soluble in ether. The fixed and volatile oils, and the diluted acids also dissolve it. As it exerts no alkaline reaction upon vegetable colours, and does not prevent the acids from reddening litmus paper, there would appear to be some reason for denying it the rank of an alkali. But it unites with some of the acids forming definite compounds, which may be procured in a separate state; and Robiquet obtained the sulphate and muriate of narcotina well crystallized. (*Journ. de Pharm.* xvii. 639, and xix. 59.) Hence many chemists, among whom is Berzelius, consider it alkaline; and, perhaps, this view of it is the most convenient. It must be admitted, however, to have a very feeble neutralizing power. With acetic acid it does not appear to form a permanent combination; for, though dissolved by cold acetic acid, it is separated by heating the solution. *Narcotina* is composed, according to an

analysis conducted with great care by Pelletier, of 65.16 parts of carbon, 4.31 of nitrogen, 5.45 of hydrogen, and 25.08 of oxygen. (*Journ. de Pharm.* xviii. 624.) According to Robiquet, its muriate consists of 4.585 parts of narcotina, and 0.409 of dry acid. (*Ibid.* xix. 63.) Narcotina may be distinguished from morphia by its insipidity, and insolubility in ether and alkaline solutions, by not affecting vegetable colours, by assuming a yellowish instead of a blood-red colour under the action of strong nitric acid, and by not producing a blue colour with the salts of iron. It is, however, reddened by a mixture of nitric and sulphuric acids. It gives a greasy stain to paper when heated upon it over a candle. Water extracts it partially from opium in consequence of the acid which the latter contains, either free or combined with the narcotina. It is usually obtained mixed with morphia in the processes for procuring that principle; and may be separated by the action of sulphuric ether, which dissolves it without affecting the morphia, and yields it upon evaporation. It may also be obtained by digesting opium in sulphuric ether, and slowly evaporating the ethereal solution, which deposits crystals of narcotina. Another mode of procuring it is to treat opium, which has been exhausted by previous maceration in water, with dilute acetic acid, filtering the solution, precipitating by an alkali, washing the precipitate with water, and purifying it by solution in boiling alcohol, from which it crystallizes as the liquid cools. Should it still be impure, the solution in alcohol and crystallization may be repeated.

Though narcotina itself is tasteless, its salts are very bitter, even more so than those of morphia. (*Berzelius.*) Their solution reddens litmus, and affords precipitates with the alkalies and infusion of galls. They have not been very accurately investigated. It has already been stated that Robiquet obtained the sulphate and muriate crystallized.

Different opinions have been advanced relative to the action of narcotina on the system. Derosne believed it to be the active principle of opium; though, upon experimenting with it, he obtained effects but little stronger than those produced by an equal dose of opium itself. Magendie found it to exercise a powerful influence upon the system of dogs. One grain dissolved in oil was sufficient to throw the animal into a state of stupor, which terminated in death in the course of twenty-four hours. This stupor was wholly different from the composed sleep produced by morphia and its preparations. He inferred that, while the latter principle exercises the remedial, anodyne, and soporific virtues of opium, the injurious excitant operation of the medicine is ascribable to the narcotina. Both Derosne and Magendie found its unpleasant effects to be modified or prevented by its conjunction with acetic acid. According to Magendie, twenty-four grains, dissolved in vinegar, may be given to a dog without destroying life. M. Baily prescribed it in the dose of sixty grains, both in the solid state and dissolved in muriatic acid, without observing from it any sensible effect. In the same state, Orfila found that it might be taken by man in very large doses with impunity; and thirty grains of it dissolved in acetic acid, produced no effect upon several patients to whom it was administered. Upon dogs, he informs us, that it is without action when dissolved in nitric or muriatic acid; but held in solution by acetic or sulphuric acid, or by olive oil, thirty or forty grains of it were sufficient to produce fatal effects. A singular circumstance noticed by the same experimenter is, that the solution in acetic or sulphuric acid occasioned violent excitement; while the contrary condition uniformly resulted from the use of that in olive oil. On the whole, we may conclude that narcotina, either in the solid form or dissolved in acids, is not possessed

of any considerable narcotic powers; and that the effects of a narcotic character which have been attributed to it, have probably arisen from the employment of a preparation not entirely freed from other principles contained in the opium. Dr. O'Shaughnessy, Professor of Chemistry in the Medical College of Calcutta, recommends narcotina very highly in intermittent fever, and believes that he has discovered in it even stronger anti-periodical properties than those of quinia. Should his reports in its favour be confirmed by further experiments, it will undoubtedly take its place among the most valuable substances of the *Materia Medica*. In the cases reported by him, it was employed in combination with muriatic acid. Given in this form, though powerfully febrifuge, it was found not to produce narcotic effects, not to constipate the bowels, and never to occasion that distressing headache and restlessness which sometimes follow the use of quinia. It proved, moreover, powerfully sudorific. It was given in doses of three grains, three times a day. Dr. O'Shaughnessy was induced to recommend its employment to his medical friends in India, from a knowledge that it had proved effectual in mild agues, in the hands of Dr. Roots and Mr. Jetson in England.

Codeia was discovered in 1832 by Robiquet in the muriate of morphia prepared according to the process of Gregory. It exists in opium combined like morphia with meconic acid, and is extracted along with that alkali in the preparation of the muriate. (See *Morphia*.) When the solution of the mixed muriates of morphia and codeia is treated with ammonia, the former alkali is precipitated, and the codeia, remaining in solution, may be obtained by evaporation and crystallization. It may be purified by treating the crystals with hot ether, which dissolves them and yields the codeia in colourless crystals by spontaneous evaporation. This alkaline product melts at 300° without decomposition. It is soluble in water, which takes up 1.26 per cent. at 60° , 3.7 at 110° , and 5.9 at 212° . When added in excess to boiling water, the undissolved portion melts and sinks to the bottom, having the appearance of an oil. It is soluble also in alcohol and ether, but is insoluble in alkaline solutions. Hence it may be separated from morphia by a solution of potassa or soda, which dissolves the morphia, and leaves the codeia. It has an alkaline reaction on test paper, and combines with acids to form salts, some of which are crystallizable, particularly the nitrate. Its capacity of saturation is almost identical with that of morphia. According to Robiquet, 1 part of muriatic acid is saturated by 7.837 of codeia, and by 7.88 of morphia. It is distinguishable, however, from the latter principle, by the different form of its crystals which are octohedral, by its solubility in boiling ether, greater solubility in water, and insolubility in alkaline solutions, and by not assuming a red colour with nitric acid, nor a blue one with the sesquisalts of iron. (*Journ. de Pharm.* xix. 91.) Tincture of galls precipitates from its solutions a tannate of codeia. Crystallized from a watery solution, it contains about six per cent. of water, which is driven off at 212° . The crystals obtained from a solution in ether contain no water. Like the other vegetable alkalies, it consists of carbon, hydrogen, oxygen, and nitrogen. Its formula is $C_{35}H_{20}O_5N$; and its combining number consequently 288.35. Dr. Gregory tried the effects of *nitrate of codeia* upon himself and several of his pupils, and found that, in a dose of three grains or less, it produced no obvious effect, but in the quantity of from four to six grains, accelerated the pulse, occasioned a sense of heat in the head and face, and gave rise to an agreeable excitement of the spirits like that resulting from intoxicating drinks, which was attended with a sense of itching upon the skin, and, after

lasting for several hours, was followed by an unpleasant depression, with nausea and sometimes vomiting. No tendency to sleep was observed, except in the state of depression. In two or three cases the medicine produced a slight purgative effect; but in others it appeared to exercise no peculiar influence on the bowels. M. Barbier of Amiens administered codeia *uncombined* in numerous cases, and observed that, in the dose of one or two grains, it acted on the nervous system, and appeared to be directed especially to the great sympathetic; as it relieved painful affections having their origin apparently in disorders of this nerve, while it exerted no influence over pains of the back and extremities supplied by nerves from the spinal marrow. He did not find it to affect the circulation, to disturb digestion, or to produce constipation. In sufficient quantity, it induced sleep, without occasioning those marks of cerebral congestion induced by opium. Dr. Miranda, of Havana, has employed it with great advantage in several bad cases of dyspepsia. On the whole, there can be no doubt that this principle has a decided action on the animal economy, and is among those upon which opium depends for its peculiar powers.

Paramorphia (thebaina) is the name given by Pelletier to a principle discovered by him in the precipitate thrown down from an infusion of opium treated with milk of lime. The precipitate being washed with water till the liquid came away colourless, and then treated with alcohol, instead of affording morphia to this solvent, as was anticipated, yielded a new alkaline principle, which was obtained separate by evaporating the alcohol, acting on the residue with ether, allowing the ethereal solution to evaporate spontaneously, and then purifying the resulting crystalline mass by dissolving it in an acid, precipitating by ammonia, and recrystallizing by means of alcohol or ether. Pelletier named it paramorphia, from its close analogy in composition with morphia, from which, however, it is quite distinct in properties. It is white, crystallizable in needles, of an acrid and styptic rather than bitter taste, fusible at about 300° , scarcely soluble in water, very soluble in alcohol and ether even when cold, and still more so when heated, and capable of combining with the acids, with which, however, it does not form crystallizable salts. Alkalies precipitate it from its acid solutions, and, unless in very concentrated solution, do not redissolve it when added in excess. It is not like morphia reddened by nitric acid, nor does it become blue with solutions of the sesquisalts of iron. From codeia it differs in never being in large crystals, in not forming crystallizable salts, in being always precipitated from its acid solutions by ammonia, and in not melting in oily drops. From narcotina, which it most resembles, it may be distinguished by its shorter crystals which want the pearly appearance of those of narcotina, by its different taste, by its much greater solubility in cold alcohol, of which 10 parts will dissolve 1 of this principle, while narcotina requires 100 parts, and by the action of nitric acid which converts it into a resin-like matter before dissolving it, while the same acid instantly dissolves narcotina. It consists of carbon, hydrogen, oxygen, and nitrogen, its formula being $C_{25}H_{14}O_8N$ (*Kane*), and its combining number consequently 205.15. The name of *thebain* was proposed for it by M. Couërbe, who was disposed to give the credit of its discovery to M. Thiboumery, the director of Pelletier's laboratory. According to Magendie, it is closely analogous, in its effects on the system, to strychnia and brucia, producing tetanic spasms in the dose of a grain. (See *Am. Journ. of Pharm.* viii. 69.)

Narcein, discovered by Pelletier in 1832, is white, in silky acicular crystals, inodorous, of a slightly bitter taste, fusible at 197° F., soluble in 375

parts of cold and 220 of boiling water, soluble also in alcohol, and insoluble in ether. It is rendered blue by the action of mineral acids so far diluted as not to decompose it; but does not, like morphia, become blue by the action of the salts of iron, nor red by that of nitric acid. It is dissolved by the acids, but does not combine with or neutralize them, and, though at first thought to be alkaline by Pelletier, is not so considered at present. It resembles the vegetable alkalies, however, in its constitution, consisting of carbon, hydrogen, nitrogen, and oxygen. Its formula is $C_{28}H_{20}O_{12}N$. Pelletier obtained it in the course of his analysis of opium. Having formed an aqueous extract of opium, he treated it with distilled water, precipitated the morphia by ammonia, concentrated the solution, filtered it, threw down the meconic acid by baryta water, separated the excess of baryta by carbonate of ammonia, drove off the excess of the ammoniacal salt by heat, evaporated the liquor to the consistence of syrup, set it aside till a pulpy matter formed containing crystals, separated and expressed this pulpy matter, then treated it with alcohol, and concentrated the alcoholic solution. This, upon cooling, deposited crystals of *narcein*, which were easily purified by repeated solution and crystallization. When mixed with meconin, which often crystallizes with it, the latter may be separated by the agency of ether. It has not been ascertained to have any influence upon the system. Two grains of it have been introduced into the jugular vein of a dog without any observable effect.

Meconin, the existence of which was announced in 1832 by M. Couërbe, is identical with a substance discovered several years previously by M. Dublanc, jun., but of which no account was published. It is perfectly white, in the form of acicular crystals, soluble in about 265 parts of cold and 18 of boiling water, very soluble in ether, alcohol, and the essential oils, fusible at 195° , volatilizable without change, and possessed of a degree of acrimony which favours the supposition that it may not be without action upon the system. It is neither acid nor alkaline, and contains no nitrogen. Meconin is obtained by precipitating the aqueous infusion of opium with ammonia, washing the precipitate with water until the latter nearly ceases to acquire colour, mixing the watery fluids, evaporating them to the consistence of molasses, setting them aside for two or three weeks, during which a mass of granular crystals is formed, then decanting the liquid, expressing the mass, and drying it with a gentle heat. The meconin may be separated from the mass by treating it with boiling alcohol of 36° Baumé, evaporating so as to obtain crystals, dissolving these in boiling water with animal charcoal, filtering the liquid while hot, and subjecting the crystals which form upon the cooling of the solution to the action of ether, which dissolves the meconin, and yields it in a state of purity by spontaneous evaporation. (*Journ. de Pharm.*, Decemb. 1832.)

Of *pseudomorphia*, as it is found in opium only as an accidental ingredient, and is not generally present, it is scarcely necessary to treat in detail. An interesting fact, however, in relation to it, and one of some toxicological importance, is that it possesses two properties hitherto considered characteristic of morphia, those namely of being reddened by nitric acid and of striking a blue colour with the salts of iron, and yet is without any poisonous influence upon the animal economy. (See *Am. Journ. of Pharm.* viii. 77, or *Journ. de Pharm.* xxi. 575.) But it differs in not forming salts with the acids, and in not decomposing iodic acid. It consists of carbon, hydrogen, oxygen, and nitrogen.

Meconic acid is in white crystalline scales, of a sour taste followed by

bitterness, fusible and volatilizable by heat, soluble in four parts of boiling water, soluble also in cold water and alcohol, with the property of reddening vegetable blues, and forming salts. Its compounds with the earths and heavy metallic oxides are generally insoluble in water. Its characteristic properties are, that it produces a blood-red colour with the sesquisalts of iron, a green precipitate with a weak solution of ammoniated sulphate of copper, and white precipitates, soluble in nitric acid, with acetate of lead, nitrate of silver, and chloride of barium. It is obtained by macerating opium in water, filtering the infusion, and adding a solution of chloride of calcium. Meconate and sulphate of lime are precipitated. The precipitate having been washed with hot water and with alcohol, is treated with dilute muriatic acid at 180° . The meconate of lime is taken up, and upon the cooling of the liquid, bimeconate of lime is deposited. This is dissolved in warm concentrated muriatic acid, which deposits pure meconic acid when it cools. It may be freed from colouring matter by neutralizing it with potassa, decomposing the crystallized meconate thus obtained by muriatic acid, and again crystallizing. Meconic acid has little or no action on the system, and is not used separately in medicine; but its natural relation to morphia requires that it should be understood.

Incompatibles. All the substances which produce precipitates with opium, do not necessarily affect its medical virtues; but the *alkalies*, and all vegetable infusions containing tannin and gallic acid, are strictly incompatible; the former separating and precipitating the active principle, the latter forming with it an insoluble compound.

The proportion of morphia which any particular specimen of opium will furnish, may be considered as the best test of its value, except that of actual trial upon the system. Good opium should yield ten or twelve per cent. of the impure morphia precipitated from the infusion by ammonia with alcohol according to the process of the United States Pharmacopœia. (See *Morphia*.) The Edinburgh College gives the following test. "A solution from 100 grains of fine opium macerated twenty-four hours in two fluid-ounces of water, filtered, and strongly squeezed in a cloth, if treated with a cold solution of half an ounce of carbonate of soda in two waters, yields a precipitate, which weighs when dry at least ten grains, and dissolves entirely in solution of oxalic acid."

Tests of Opium. It is sometimes highly important to be able to ascertain the presence or absence of opium in any suspected mixture. As meconic acid and morphia have been found only in the products of the poppy, if either or both of them be shown to exist in any substance, very strong evidence is afforded of the presence of opium in that substance. Our tests should, therefore, be applied in reference to the detection of these two principles. If an aqueous infusion of the substance examined yield a red colour with the tincture of chloride of iron, there is presumptive evidence of the presence of meconic acid. Greater certainty may be obtained by the following process. Add in excess to the filtered liquor a solution of acetate of lead. If opium be present, there will be a precipitate of meconate of lead, and the acetates of morphia and lead will remain in solution. The precipitate is then to be suspended in water and decomposed, either by adding a little diluted sulphuric acid, which forms the sulphate of lead and leaves the meconic acid in solution, or by passing through it a stream of sulphuretted hydrogen, removing by filtration the precipitated sulphuret of lead, and heating the clear liquor so as to drive off the sulphuretted hydrogen. With the clear liquor thus obtained, if it contain meconic acid, the tincture of chloride of iron will produce a striking red colour, the ammo-

niated sulphate of copper a green precipitate, and acetate of lead, nitrate of silver, and chloride of barium, white precipitates soluble in nitric acid. It has been ascertained that hydrosulphocyanic acid or a sulphocyanuret, and consequently saliva which occasionally contains it, produce a red colour with the sesquisalts of iron resembling that produced by meconic acid; but, according to Mr. Everitt, this colour is entirely and at once destroyed by a solution of corrosive sublimate, which has no effect on the red colour of the meconate of iron. (See *Am. Journ. of Pharm.* xii. 88.) On the contrary, chloride of gold reddens a solution of hydrosulphocyanic acid or a sulphocyanuret, but not of meconic acid. Pereira says the acetates also redden the sesquisalts of iron; but they do not afford the results above mentioned with acetate of lead and chloride of barium. To test the presence of morphia, the liquid from which the meconate of lead has been precipitated, and which may be supposed to contain the acetates of morphia and lead, must be freed from the lead by a stream of sulphuretted hydrogen, and then from the sulphuretted hydrogen by heat; after which, the following reagents may be applied:—viz. 1. nitric acid, which colours the morphia red; 2. iodic acid, which is decomposed by the morphia with the extrication of iodine, which colours the liquid reddish-brown, and, if starch is present, unites with it to form a blue compound; 3. solution of ammonia, which, if carefully added so as not to be in excess, throws down a precipitate of morphia soluble in a great excess of that alkali or of potassa; and 4. tannic acid, which precipitates an insoluble tannate of morphia. If the precipitate thrown down by ammonia afford a deep red colour, becoming yellow, with nitric acid, and a blue colour with the sesquichloride of iron, the proof may be considered as complete.

The London College judiciously directs that opium, before being used, be carefully separated from all foreign substances, especially those which are external. The College also directs that it should be kept in two states—*soft*, fit to form pills; and *hard*, by drying it with the aid of a water-bath, so that it may be pulverized.

Medical Properties and Uses. Opium is a stimulant narcotic. Taken by a healthy person, in a moderate dose, it increases the force, fulness, and frequency of the pulse, augments the temperature of the skin, invigorates the muscular system, quickens the senses, animates the spirits, and gives new energy to the intellectual faculties. Its operation, while thus extending to all parts of the system, is directed with peculiar force to the brain, the functions of which it excites sometimes even to intoxication or delirium. In a short time this excitation subsides; a calmness of the corporeal actions, and a delightful placidity of mind succeed; and the individual, insensible to painful impressions, forgetting all sources of care and anxiety, submits himself to a current of undefined and unconnected, but pleasing fancies; and is conscious of no other feeling than that of a quiet and vague enjoyment. At the end of half an hour or an hour from the administration of the narcotic, all consciousness is lost in sleep. The soporific effect, after having continued for eight or ten hours, goes off, and is generally succeeded by more or less nausea, headache, tremors, and other symptoms of diminished or irregular nervous action, which soon yield to the recuperative energies of the system; and unless the dose be frequently repeated, and the powers of nature worn out by over-excitement, no injurious consequences ultimately result. Such is the obvious operation of opium when moderately taken; but other effects, very important in a remedial point of view, are also experienced. All the secretions, with the exception of that from the skin, are either suspended or diminished; the peristaltic motion of the bowels is les-

sened; pain and inordinate muscular contraction, if present, are allayed; and general nervous irritation is composed, if not entirely relieved.

When large doses are taken, the period of excitement and exhilaration is shorter; the soporific and anodyne effects are more intense and of longer duration; and the succeeding symptoms of debility are more obvious and alarming.

In quantities sufficient to destroy life, opium scarcely produces any sensible increase of the general powers of the system, but almost immediately reduces the frequency, though not the force, of the pulse, diminishes muscular strength, and brings on languor and drowsiness, which soon eventuate in a deep apoplectic sleep. A stertorous respiration; a dark suffusion of the countenance; a full, slow, and labouring pulse; an almost total insensibility to external impressions; and—when a moment of consciousness has been obtained by violent agitation, or powerfully irritating applications—a confused state of intellect, and an irresistible disposition to sink back into comatose sleep, are symptoms which, for the first few hours, attend the operation of the poison. Though not signs of an elevated condition of the bodily powers, neither do they imply a state of pure, unmixed debility. The pulse is, indeed, slow; but it is often so full, and so powerful in its beat, that the practitioner feels himself obliged to use the lancet. In the space, however, of a few hours, varying according to the quantity of the narcotic taken, and the powers of the patient's constitution, a condition of genuine debility ensues; and this condition will be hastened in point of time, though it will be more under the control of remedies, if the opium be removed artificially from the stomach. Called to an individual labouring under the influence of a fatal dose of opium, at a period from six to eight hours after it has been swallowed, the practitioner will generally find him with a cool, clammy skin, cold extremities; a pallid countenance; a feeble, thread-like, scarcely perceptible pulse; a slow, interrupted, almost gasping respiration; and a torpor little short of absolute, death-like insensibility. Death soon follows, unless relief is afforded.

No appearances are revealed by the dissection of those who have died of the immediate effects of opium, which can be considered as affording satisfactory evidence of its mode of operation. The redness occasionally observed in the mucous membrane of the stomach, is by no means constantly present, and is ascribable rather to the irritating substances prescribed as remedies, or to the spirituous vehicle in which the poison has been swallowed, than to the action of the poison itself. Such at least is the inference drawn by Nysten from his experiments and observations; and Orfila states that the stomachs of dogs which he had killed by opium internally administered, did not present the slightest vestige of inflammation. The force of the medicine is directed to the cerebral and nervous functions; and death is produced by a suspension of respiration arising from the want of due influence from the brain. The section of the par vagum on both sides has not been found to prevent or retard the death of animals to which large doses of opium have been given, nor even materially to modify its narcotic effects. (*Nysten, quoted by Orfila.*) It would seem, therefore, that the active principle is conveyed into the circulation, and operates upon the brain, and probably upon the nervous system at large, by immediate contact with their interior structure. It is an error to attribute the anodyne, sedative, and soporific effects of the medicine to the previous excitement. They are, as much as this very excitement, the direct results of its action upon the brain. It is in the state of exhaustion and collapse which ensue after the peculiar influence of the opium has ceased, that we are to look for

an illustration of that principle of the system, by which any great exaltation of its energies above the natural standard is followed by a corresponding depression. We may be permitted to advance the conjecture, that the excitement which almost immediately supervenes upon the internal use of opium, is produced by means of nervous communication; while the succeeding narcotic effects are attributable to its absorption and entrance into the circulation; and the prostration of all the powers of the system which ultimately takes place, is a necessary consequence of the agitation into which the various organs have been thrown.

On some individuals opium produces very peculiar effects, totally differing from the ordinary results of its operation. In very small quantities it occasionally gives rise to excessive sickness and vomiting, and even spasm of the stomach; in other cases it produces restlessness, headache, and delirium; and we have known it, even in large doses, to occasion obstinate wakefulness. The headache, want of appetite, tremors, &c., which usually follow, in a slight degree, its narcotic operation, are uniformly experienced by some individuals to such an extent, as to render the use of the medicine very inconvenient. It is possible that some of these disagreeable effects may arise not from the meconate of morphia contained in the opium, but from some other of its ingredients, and those which do result from the meconate, may not be produced by other salts of morphia. It has, in fact, been found that the operation of opium may often be favourably modified by changing the state of combination in which its active principle naturally exists. Dissolved in vinegar or lemon juice, it had been known to act in some instances more pleasantly and effectually than in substance, or in the state of tincture, long before physicians had learned to explain the phenomenon by referring it to the production of an acetate or citrate of morphia. When upon the subject of morphia, we shall take occasion to treat of the medical properties of this principle in its various combinations.

An occasional effect of opium, which has not yet been alluded to, is a disagreeable itching or sense of pricking in the skin, which is sometimes attended with a species of miliary eruption. We have found the effect to result equally from all the preparations of this narcotic.

The general operation of opium may be obtained by injecting it into the rectum, or applying it to the surface of the body, especially upon a part denuded of the cuticle. It has appeared to us, when thus applied, to produce less general excitement, in proportion to its other effects, than when administered by the mouth; but we do not make the statement with entire confidence. It is said that when introduced into the cellular membrane, it acts with great energy; and when thrown into the cavity of the peritoneum speedily produces convulsions and death. Injected into the cavity of the heart, it impairs, or altogether destroys the powers of that organ.

The local effects of opium are of a similar character with those which follow its general operation. An increased action of the part is first observable; then a diminution of its sensibility and contractility; and the latter effect is more speedy, more intense, and of longer continuance, the larger the quantity in which the narcotic is applied.

In all parts of the world, opium is habitually employed by many with a view to its exhilarating and anodyne influence. This is particularly the case among the Mahomedans and Hindoos, who find in this narcotic the most pleasing substitute for those alcoholic drinks which are interdicted by the precepts of their religion. In India, Persia, and Turkey, it is consumed in immense quantities; and many nations of the East smoke opium as those

of the West smoke tobacco. This is not the place to speak of the fearful effects of such a practice upon both the intellectual and bodily faculties.

The use of opium as a medicine can be clearly traced back to Diagoras, who was nearly contemporary with Hippocrates; and it was probably employed before his time. It is at present more frequently prescribed than perhaps any other article of the *materia medica*. Its extensive applicability to the cure of disease, will be rendered evident by a view of the indications which it is calculated to fulfil. 1. It is excitant in its primary action. In low or typhoid complaints, requiring a supporting treatment, it exalts the actions of the arterial and nervous systems, and in moderate doses frequently repeated, may be employed with advantage in conjunction or alternation with other stimulants. 2. It relieves pain more speedily and effectually than any other medicine with which we are acquainted. If possessed of no other property than this, it would be entitled to high consideration. Not to mention cancer, and those other incurable affections, which, if not alleviated by opium, would render the remainder of life one continued scene of torture; we have numerous instances of painful diseases which are not only temporarily, but entirely cured by the remedy, and there is scarcely a complaint in the catalogue of human ailments, in the treatment of which it is not occasionally demanded for the relief of suffering, which, if allowed to continue, might aggravate the disorder, and protract, if not prevent a cure. 3. Another very important indication, which, beyond any other narcotic, it is capable of fulfilling, is the production of sleep. For this purpose it is given in a great variety of diseases—whenever, in fact, morbid vigilance exists, not dependent on acute inflammation of the brain. Among the complaints in which it proves most serviceable in this way, is delirium tremens, or the mania of drunkards, in which it is frequently sufficient of itself to effect a cure. Opium produces sleep in two ways; first, by its direct operation on the brain, secondly, by allaying that morbid nervous irritation upon which wakefulness generally depends. In the latter case it may frequently be advantageously combined with camphor or Hoffmann's anodyne. 4. Opium is powerfully antispasmodic. No medicine is so efficient in relaxing spasm, and in controlling those irregular muscular movements which depend on unhealthy nervous action. Hence its great importance as a remedy in tetanus; colic; spasm of the stomach attending gout, dyspepsia, and cholera; spasm of the ureters in nephritis, and of the biliary ducts during the passage of calculi; and in various convulsive affections. 5. Probably dependent upon a similar influence over the nervous system, is the property which it possesses of allaying general and local irritations, whether exhibited in the nerves or blood-vessels, provided the action do not amount to positive inflammation; and even in this case it is sometimes prescribed with advantage. Hence its use in composing restlessness, quieting cough, and relieving nausea, tenesmus, and strangury. 6. In suppressing morbid discharges, it answers another indication which fits it for the treatment of a long list of diseases. This effect it is, perhaps, enabled to produce by diminishing the nervous energy upon which secretion and muscular motion depend. Upon this principle it is useful in diarrhoea, when the complaint consists merely in increased secretion into the bowels, without high action or organic derangement; in consumption, chronic catarrh, humoral asthma, and other cases of morbidly increased expectoration; in diabetes, and in certain forms of hemorrhage, particularly that from the uterus, in combination with other remedies. 7. It remains to mention one other indication—that of producing perspiration—in fulfilling which opium, conjoined with small doses of emetic medicines, is pre-eminent. No diaphoretic is so powerful as a com-

bination of opium and ipecacuanha; and none is so extensively employed. We shall speak more fully of this application of the remedy under the head of *Pulvis Ipecacuanhæ et Opii*. It is here sufficient to say, that its beneficial effects are especially experienced in rheumatism, the bowel affections, and certain forms of pulmonary disease.

From this great diversity of properties, and the frequent occurrence of those morbid conditions in which opium affords relief, it is often prescribed in the same disease to meet numerous indications. Thus, in idiopathic fevers, we frequently meet with morbid vigilance and great nervous irritation, combined with a low condition of the system. In typhous pneumonia, there is the same depression of the vital powers, combined with severe neuralgic pains, and much nervous irritation. In diarrhœa, besides the indications presented by the spasmodic pain and increased discharge, there is a strong call for the diaphoretic operation of the opium. It is unnecessary to multiply instances. There is hardly a complaint which does not occasionally present a complication of symptoms demanding the use of this remedy.

But a medicine possessed of such extensive powers may do much injury if improperly directed; and conditions of the system frequently occur, in which, though some one of the symptoms calls for its use, others, on the contrary, are incompatible with it. Thus, opium is contra-indicated by a high state of inflammatory excitement, which should be reduced before we can with propriety venture upon its employment; and, when there is any doubt as to the sufficiency of the reduction, the opium should be given in combination with tartarized antimony or ipecacuanha, which modify its stimulant operation, and give it a more decided tendency to the skin. It is also contra-indicated by inflammation of the brain or strong determination of blood to the head, by deficient secretion from inflamed mucous membranes, as in the early stages of bronchitis, and generally by constipation of the bowels. When, however, the constipation depends upon intestinal spasm, as in colic, it is sometimes relieved by the antispasmodic action of the opium; and the binding effects of the medicine may generally be counteracted by the use of laxatives.

Opium is usually administered in substance or in tincture. In the former state it is given in the shape of pill, which, as a general rule, should be formed out of powdered opium, as it is thus more readily dissolved in the liquors of the stomach, and therefore operates more speedily and effectually than when made, as it sometimes is, immediately from the plastic mass. There is no medicine of which the dose is more variable, according to the habits of the patient, the nature of his complaint, or the purpose to be effected. While in catarrh and diarrhœa, we often prescribe not more than one-fourth or one-third of a grain; in tetanus and some other nervous affections, it has been administered, without abating the violence of the symptoms, in the enormous quantity of two drachms in twenty-four hours; and in a case of cancer of the uterus, under the care of the late Drs. Monges and La Roche of this city, the quantity is stated to have been gradually increased, till the amount taken during one day, either in the shape of tincture or in substance, was equivalent to more than three ounces. The medium dose, in ordinary cases of disease, to produce the anodyne and soporific effects of the medicine, is one grain.

Opium may often be applied with great advantage by the rectum. In this way it operates most advantageously in cases of obstinate vomiting, of painful nephritic and uterine affections, of strangury from blisters, and of dysenteric tenesmus. It may be employed as a suppository, or in the form of

enema made with laudanum and a small quantity of viscid liquid, as flaxseed tea, mucilage of gum Arabic, or starch prepared with hot water. The quantity, as a general rule, may be three times that administered by the mouth; but the relative susceptibility of the stomach and rectum in different persons, is not always the same; and the effects produced by the narcotic given by injection, are sometimes much greater than was anticipated. The practitioner, moreover, should take into consideration the previous habits of the patient. In an individual who has long been accustomed to take opium internally, and whose stomach will receive large doses with impunity, it is possible that the rectum may not have lost, in a proportionate degree, its absorbing power or susceptibility; and that serious consequences might result by adhering, in such a case, to the general rule as to the relative quantity to be given in the way of enema or suppository.

In some one of its liquid preparations, opium is often used externally as an addition to collyria in ophthalmia, to injections in gonorrhœa, and to lotions in various complaints of the skin, and external pains, as those of gout and rheumatism. It is also used as a local anodyne in the state of powder, made into a plaster or cataplasm.

When opium has been taken in an overdose, the only effectual mode of relief is immediately to evacuate the stomach, either by means of the stomach-pump, or when this is not attainable, by the more active emetics, such as tartarized antimony, sulphate of zinc, or sulphate of copper, conjoined with ipecacuanha. Emetics are preferable to the stomach-pump, when opium has been swallowed in substance; as the capacity of the tube is insufficient to admit of the passage of the masses in which the poison is sometimes taken. The operation of the emetic should be promoted by a very free use of warm drinks, by irritating the fauces with a feather, by keeping the patient in motion, and, if the insusceptibility to the action of the remedy is very great, by dashing cold water upon the head and shoulders, thus counteracting, for a moment, the narcotic influence of the opium upon the brain, and enabling this organ to receive and transmit the necessary impressions. For the same purpose it has been recommended to pass a current of electricity through the brain. After the evacuation of the poison, the chief indication is to obviate the debility which generally supervenes, and which, in cases where the quantity of the narcotic has been large, or has remained long in the stomach, is sometimes alarming and even fatal. For this purpose, the carbonate of ammonia or the aromatic spirit of ammonia, with wine whey, may be employed internally, and sinapisms and stimulant frictions applied to the surface. The practitioner should not despair even if called at the last moment. The stomach tube may be applied at any period; and it is possible that, even without an evacuation of the stomach, a little assistance may enable the system to resist successfully the prostrating influence of the poison, if not taken in an overwhelming dose. Should all other measures fail, resort may be had to artificial respiration, by which the functions of the lungs and heart may possibly be sustained till the brain has struggled through its conflict with the narcotic, and is enabled to resume its natural action. Brodie has demonstrated that death from many of the narcotics results from a suspension of the cerebral influence necessary to sustain the respiratory function, and that the heart ceases to act in consequence of the cessation of respiration. If this can be restored artificially before the contractions of the heart have entirely ceased, the circulation may continue, and life be supported for a time without aid from the brain, which now receives a supply of arterial blood, and is thus better enabled to rise above the repressing action of the opium. As this narcotic

does not produce a structural derangement, but operates chiefly upon the nervous power, a favourable result is more likely to be experienced than in cases of poisoning from some other articles of the same class. Several cases are on record, in which patients, apparently in the very last stage, were saved by a resort to artificial respiration.* We have seen a notice by Dr. Page, of Valparaiso, in Chili, of the successful application, in a case of great prostration and insensibility, of the powerfully excitant current of electric fluid from an electro-magnetic machine.

Pastinaca Opopanax. Willd. *Sp. Plant.* i. 1466; Woodv. *Med. Bot.* p. 122. t. 47.—*Opopanax Chironium.* De Candolle. This species of parsnip, usually called *rough parsnip*, has a thick, yellow, fleshy, perennial root, which sends up annually a strong branching stem, rough near the base, about as thick as a man's thumb, and from four to eight feet in height. The leaves are variously pinnate, with long sheathing petioles, and large, oblong, serrate leaflets, of which the terminal one is cordate, others are deficient at their base upon the upper side, and the whole are hairy on their under surface. The flowers are small, yellow, and form large flat umbels at the termination of the branches.

The plant is a native of the Levant, and grows wild in the South of France, Italy, and Greece. When the base of the stem is wounded, a juice exudes, which, when dried in the sun, constitutes the opopanax of commerce. Some authors state that it is obtained from the root. A warm climate appears necessary for the perfection of the juice, as that which has been collected from the plant in France, though similar to opopanax, is of inferior quality. The drug is brought from Turkey. It is said to come

* One case was that of an infant, ten days old, who had received by mistake from twenty-five to thirty drops of laudanum intended for the mother, had completely lost the power of deglutition, was comatose, and had had several convulsions. Artificial respiration was sustained two or three hours. (See case by Dr. Ogilvie, in the *N. Am. Med. and Surg. Journ.* vol. iii. p. 277.) Another case was that of an adult female, for a notice of which, see the *American Journal of the Medical Sciences*, vol. xx. p. 450.

also from the East Indies; but Ainslie states that he has never met with it in any Indian medicine bazaar.

It is sometimes in tears, but usually in irregular lumps or fragments, of a reddish-yellow colour, speckled with white on the outside, paler within, and when broken exhibiting white pieces intermingled with the mass. Its odour is strong, peculiar, and unpleasant; its taste bitter and acrid. Its sp. gr. is 1.622. It is inflammable, burning with a bright flame. In chemical constitution it is a gum-resin, with an admixture of other ingredients in small proportion. The results of its analysis by Pelletier were from 100 parts, 33.4 of gum, 42 of resin, 4.2 of starch, 1.6 of extractive, 0.3 of wax, 2.8 of malic acid, 9.8 of lignin, 5.9 of volatile oil and loss, with traces of caoutchouc. Water by trituration dissolves about one-half of the gum-resin, forming an opaque milky solution, which deposits resinous matter on standing, and becomes yellowish. Both alcohol and water distilled from it retain its flavour; but only a very minute proportion of oil can be obtained in a separate state.

Medical Properties and Uses. Popanax was formerly employed as an antispasmodic and deobstruent, in hypochondriasis, hysteria, asthma, and chronic visceral affections, and as an emmenagogue in suppression of the menses; but it is now generally regarded as a medicine of very feeble powers, and in this country is scarcely ever used. Its dose is from ten to thirty grains. W.

ORIGANUM. *Sex. Syst.* Didynamia Gymnospermia.—*Nat. Ord.* Lamiales or Labiatae.

Gen. Ch. *Strobile* four-cornered, spiked, collecting the calyces. *Corolla* with the upper lip erect and flat, the lower three-parted, with the segments equal. *Willd.*

Origanum vulgare. Willd. *Sp. Plant.* iii. 135; Woodv. *Med. Bot.* p. 344. t. 123. *Origanum* or *common marjoram* is a perennial herb, with erect, purplish, downy, four-sided, trichotomous stems, which rise about eighteen inches high, and bear opposite, ovate, entire, somewhat hairy leaves, of a deep yellowish-green colour. The flowers are numerous, of a pinkish-purple or rose colour, disposed in roundish, paniced spikes, and accompanied with ovate reddish bractes, longer than the calyx. This is tubular, and five-toothed, with nearly equal segments. The corolla is funnel-shaped, with the upper lip erect, bifid, and obtuse, the lower trifid, blunt, and spreading. The anthers are double, the stigma bifid and reflexed.

The plant is a native of Europe and America. In this country it grows along the road sides, and in dry stony fields and woods, from Pennsylvania to Virginia, and is in flower from June to October; but it is not very abundant, and is seldom collected for use. The oil, which is the part chiefly employed, is imported from Europe.

Properties. Common marjoram has a peculiar agreeable aromatic odour, and a warm, pungent taste. These properties it owes to a volatile oil, which may be separated by distillation. (See *Oleum Origanum*.)

Medical Properties and Uses. It is gently tonic and excitant, and has been used in the form of infusion as a diaphoretic and emmenagogue, and externally as a fomentation; but it is at present scarcely employed.

ORIGANUM MAJORANA. Herba. *Dub.*

Sweet Marjoram.

Marjolaine, *Fr.*; Majoran, Wurstkraut, *Germ.*; Maggiorana, *Ital.*; Meiorana, *Span.*

ORIGANUM. See ORIGANUM.

Origanum Majorana. Willd. *Sp. Plant.* iii. 137; Woodv. *Med. Bot.* p. 345. t. 124. This species of *Origanum* has a perennial root with numerous stems, which are woody, branching, four-sided, and a foot and a half high. The leaves are sessile, in pairs, ovate, obtuse, entire, downy, and of a pale green colour. The flowers are small, white, and appear successively between the bracteal leaves, which are numerous, and form round compact spikes, of which three or four are placed at the extremity of each peduncle. The corolla is funnel-shaped, with the upper lip erect and roundish, the under divided into three pointed segments.

Sweet marjoram grows wild in Portugal and Andalusia, and is cultivated as a garden herb in other parts of Europe and in the United States. Some authors, however, consider the *O. Majoranoïdes*, which is a native of Barbary, and closely allied to the *O. Majorana*, as the type of the sweet marjoram of our gardens.

This plant has a pleasant odour, and a warm, aromatic, bitterish taste, which it imparts to water and alcohol. By distillation with water it yields a volatile oil, which is directed by the Edinburgh College among their preparations, though the plant has been rejected.

It is tonic and gently excitant, but is used more as a condiment in cookery than as a medicine. In domestic practice, its infusion is much employed by the vulgar to hasten the tardy eruption in measles and other exanthematous diseases.

OS. *U. S.*

Bone.

Off. Syn. OSSA. *Dub.*

Os, *Fr.*; Knochen, *Germ.*; Ossa, *Ital.*; Huesos, *Span.*

Bones are employed in several pharmaceutical processes, and those derived from the domestic quadrupeds, especially the ox, may be assumed as the kind intended for official use. They have been expunged from the official list of the Edinburgh College, though used by the College for preparing phosphate of soda.

Properties, &c. They are solid, white substances, of a lamellated texture, constituting the skeleton of the superior orders of animals, of which they form the hardest and densest parts. They consist of a cellular gelatinous tissue, the cavities of which are filled up with certain earthy salts, to be mentioned presently. When subjected to destructive distillation, in close vessels, they are decomposed without alteration of shape, lose about three-sevenths of their weight, become brittle, and are converted into a black substance, containing the earthy salts of the bone, and constituting the species

of animal charcoal called *bone-black*. (See *Carbo Animalis*.) The portions which distil over consist of the usual ammoniacal products derived from animal matter. (See *Ammonia Murias*.) When calcined in open vessels they lose more of their weight, and are converted into a white friable substance, consisting of the incombustible part, and commonly called *bone-earth* or *bone-ash*; and a similar residue is obtained by calcining horn. (See *Cornu Ustum*.) Treated with boiling water, a small portion of the gelatinous matter is dissolved; but when acted on by water in a *Papin's digester*, the whole of it is taken up, and the earthy salts, deprived of their cement, crumble into powder, and become diffused through the solution. When subjected to the action of dilute muriatic acid, the earthy salts are dissolved, and the bone softens without losing its shape, and becomes semitransparent and flexible. The portion which remains unattacked by the acid is the gelatinous tissue, and may be converted into gelatin by long boiling. This portion of bone is nutritious, and has been prepared so as to form a wholesome aliment by M. d'Arcet. His process for obtaining it consists in digesting bones in weak muriatic acid for seven or eight days, occasionally renewing the acid, plunging them for a few moments in boiling water, and then subjecting them to a strong current of cold water. The pure animal matter thus procured is made into cakes called *portable soup*, (*tablettes de bouillon*.) by dissolving in water, concentrating the solution until it gelatinizes, and drying the matter obtained.

Composition. The bones of different animals, and of the same animal at different ages, vary somewhat in their composition. Dry ox-bones, according to Berzelius, consist of animal matter 33.3, bone-phosphate of lime 55.45, carbonate of lime 3.85, fluoride of calcium 2.90, soda, chloride of sodium, water, &c. 2.45, phosphate of magnesia 2.05 = 100. Fourcroy and Vauquelin's results give a larger quantity of animal matter and carbonate of lime, and a smaller of bone-phosphate. Fluoride of calcium is not always present in recent bone, but is invariably found in fossil bones. Human bones differ somewhat in the proportions of their constituents, and in containing traces of iron and manganese. *Bone-phosphate of lime*, so called to distinguish it from the other calcareous phosphates, consists of three eqs. of phosphoric acid and eight of lime.

Uses. Bones are applied to numerous uses. Burnt to whiteness, they furnish bone-phosphate of lime, from which phosphorus and all its compounds are either directly or indirectly obtained. (See *Phosphorus*.) Subjected to destructive distillation, they yield *impure carbonate of ammonia*, and empyreumatic oil; and a carbonaceous residue is left, called *bone-black*. Calcined, pulverized, and washed, they form the material of which *cupels* are made. As bone-dust, they form an excellent manure. Deprived of their earthy portion by weak acids, they furnish a nutritious article of diet. By proper treatment with water they furnish gelatin, applicable not only to the purposes of size and common glue, but also to those of the finer sorts of gelatin, called isinglass, in making animal jellies, and for the fining of wines. (See *Ichthyocolla* and *Cornu*.) The hoof-bones of the ox, when boiled with water, furnish a peculiar oil, called *neats-foot oil*. (See *Oleum Bubulum*.)

OVUM. *Lond., Ed.**Egg.*

“Phasianus Gallus. *Ovum.*” *Lond.* “Egg of Phasianus gallus.” *Ed.*
Cenf., Fr.; Ei, Germ.; Ovo, Ital.; Huevo, Span.

The common dunghill fowl is supposed to have come originally from India, where it is found in a wild state. It is now domesticated in almost all parts of the globe.

The egg, which is the only officinal product, consists of 1. an exterior covering called the shell; 2. a white, semi-opaque membrane, lining the internal surface of the shell; 3. the white; 4. the yolk. Other distinct parts are recognised by the comparative anatomist, but they have no peculiar interest for the practical physician or pharmacist.

1. The shell—*testa ovi* or *putamen ovi*—consists, according to Vauquelin, chiefly of carbonate of lime, with animal matter, and a minute proportion of phosphate of lime, carbonate of magnesia, oxide of iron, and sulphur. When exposed to a high degree of heat in the open air, the carbonic acid is driven off, the animal matter consumed, and lime is left nearly pure.

2. The membrane lining the shell appears to be of an albuminous nature.

3. The white—*albumen ovi*—is a glairy viscid liquid contained in very delicate membranes, without odour or taste, readily soluble in water, coagulable by the stronger acids, by alcohol, and by a heat of 160° F. Exposed in thin layers to a current of air it becomes solid, retaining its transparency and solubility in water. By coagulation it is rendered sapid, white, opaque, and insoluble. At a temperature of 212°, one part of it renders one thousand parts of water in which it has been dissolved opaque. It contains, according to Dr. Bostock, in one hundred parts, 85 of water, 12 of pure albumen, 2·7 of mucus or uncoagulable matter, and 0·3 of saline substances, including soda with traces of sulphur. The white of egg is precipitated by chloride of tin, chloride of gold, subacetate of lead, corrosive sublimate, and tannin. When kept in the fluid state it soon putrefies; but if carefully dried without coagulation it may be long preserved without change, and may be applied in a state of solution to the same purposes as in its original condition.

4. The yolk—*vitellus ovi*—is inodorous, of a bland oily taste, and forms a milky emulsion when agitated with water. It contains water, albumen, a mild fixed oil, and a colouring matter. By heat it is coagulated into a granular solid, which yields the oil by expression.

Medical Properties and Uses. Eggs are applied to various purposes in medicine and pharmacy. The shells powdered and levigated may be used beneficially as an antacid in diarrhœa. In common with oyster shells, they possess the advantage of uniting intimately animal matter with the carbonate of lime, the particles of which are thus more thoroughly isolated, and prove more acceptable to the stomach, than chalk in the finest state of division to which the latter can be brought by mechanical means. The dose and mode of preparation are the same with those of oyster shell. (See *Testa.*)

The *white* of the egg is used chiefly for the clarification of liquids, which it effects by involving, during its coagulation, the undissolved particles, and rising with them to the surface or subsiding. It is highly recommended as an antidote for corrosive sublimate and sulphate of copper, with which it forms insoluble and comparatively inert compounds. It is sometimes also used for the suspension of insoluble substances in water, but is inferior for

this purpose to the yolk, and even to mucilage of gum Arabic. Agitated briskly with a lump of alum it coagulates, at the same time dissolving a portion of the alum, and thus forming an astringent poultice, which may be advantageously applied between folds of gauze over the eye, in some states of ophthalmia. (See *Cataplasma Aluminis*.)

The yolk in its raw state is thought to be laxative, and is a popular remedy in jaundice. If beneficial in this complaint, it is probably in consequence of affording a mild nutritious diet, acceptable to the stomach, and easily digested. In dyspepsia it is, from this cause, highly useful. The late Dr. Parrish, of Philadelphia, found much advantage from recommending to his dyspeptic patients the habitual use of the yolk of egg beat up with water and a little ginger. In pharmacy, the yolk is highly useful as an intermedium between water and insoluble substances, such as the balsams, turpentine, oils, &c. It is a mistake to employ the white, instead of the yolk of eggs, in the preparation of emulsions.

PANAX. U. S., Secondary.

Ginseng.

“The root of *Panax quinquefolium*.” U. S.

Ginseng, *Fr., Germ., Span.*; Ginsen, *Ital.*

PANAX. *Sex. Syst.* Pentandria Digynia. (Polygamia Diœcia, *Linn.*)—*Nat. Ord.* Araliacæ.

Gen. Ch. Flowers polygamous. Umbel simple. Calyx five-toothed. Corolla of five petals. Berry inferior, subcordate, two, sometimes three-seeded. Calyx in the male flower entire. *Nuttall.*

Panax quinquefolium. Willd. *Sp. Plant.* iv. 1124; Woodv. *Med. Bot.* p. 149. t. 58; Bigelow, *Am. Med. Bot.* ii. 82. The ginseng has a perennial root, which sends up annually a smooth, round stem, about a foot high, and divided at the summit into three leafstalks, each of which supports a compound leaf, consisting of five, or more rarely of three or seven petiolate, oblong obovate, acuminate, serrate leaflets. The flowers are small, greenish, and arranged in a simple umbel, supported by a peduncle, which rises from the top of the stem in the centre of the petioles. The fruit consists of kidney-shaped, scarlet berries, crowned with the styles and calyx, and containing two, and sometimes three seeds.

The plant is indigenous, growing in the hilly regions of the Northern, Middle, and Western States, and preferring the shelter of thick, shady woods. The root is the part employed. This is collected in considerable quantities in Ohio and Western Virginia, and brought to Philadelphia and other cities on the sea-board for the purpose of exportation to China, where it is highly valued. Some suppose the ginseng plant of Chinese Tartary to be the same as ours, others consider it a different species—the *Panax Schinseng* of Nees von Esenbeck. While supplied with this drug exclusively from their own native sources, which furnished the root only in small quantities, the Chinese entertained the most extravagant notions of its virtues, considering it as a remedy for all diseases, and as possessing almost miraculous powers in preserving health, invigorating the system, and prolonging life. It is said to have been worth its weight in gold at Pekin; and the first shipments made from North America to Canton, after the discovery of the root in this country, were attended with enormous profits.

But the subsequent abundance of supply has greatly diminished its value, and though it still occasionally forms a part of the investments for Canton, it has become an object of less importance than formerly.

The root is fleshy, somewhat spindle-shaped, from one to three inches long, about as thick as the little finger, and terminated by several slender fibres. Frequently there are two portions, sometimes three or more, connected at their upper extremity, and bearing a supposed, though very remote resemblance to the human figure, from which circumstance it is said that the Chinese name *ginseng* originated. When dried, the root is yellowish-white and wrinkled externally, and within consists usually of a hard central portion, surrounded by a soft whitish bark. It has a feeble odour, and a sweet, slightly aromatic taste, somewhat analogous to that of liquorice root. It has not been accurately analyzed, but is said to be rich in gum and starch. It is sometimes submitted, before being dried, to a process of clarification, which renders it semitransparent and horny, and enhances its value as an article of export. The extraordinary medical virtues formerly ascribed to ginseng, had no other existence than in the imaginations of the Chinese. It is little more than a demulcent, and in this country is not employed as a medicine. Some persons, however, are in the habit of chewing it, having acquired a relish for its taste; and it is chiefly to supply the wants of these that it is kept in the shops. W.

PAPAYER. *U.S., Lond., Ed.*

Poppy-heads.

"The ripe capsules of *Papaver somniferum*." *U.S.* "*Papaver somniferum. Capsulæ maturæ.*" *Lond.* "Capsules of *Papaver somniferum*, not quite ripe." *Ed.*

Off. Syn. PAPAVER SOMNIFERUM. *Capsulæ maturæ. Dub.*

Capsules des pavots, *Fr.*; Kapseln des weissen Mohns, *Germ.*; Capidel papavero, *Ital.*; Cabezas de amapola, *Span.*

See OPIUM.

In England the poppy is cultivated chiefly for its capsules, which are gathered as they ripen, and taken to market enclosed in bags. The Edinburgh College properly directs them to be collected before they are quite ripe, as they contain at that period, more of the active milky juice. They are occasionally imported into this country; but as no effect is produced by them, which cannot be as readily obtained from opium, or some one of its preparations, they are little employed; and the framers of the United States Pharmacopœia did not consider them entitled to a place among the articles of the *Materia Medica*.

The dried poppy capsules vary in size from the dimensions of a small egg to those of the fist. They are of a spheroidal shape, flattened below, and surmounted by a crown-like expansion—the persistent stigma—which is marked by numerous diverging rays that rise somewhat above its upper surface, and appear to be prolongations of partial septa, or partitions, proceeding along the interior circumference of the capsule from the top to the bottom. In the recent state, the seeds, which are very numerous, adhere to these septa; but in the dried capsule they are loose in its cavity. The capsules of the black poppy are smaller and more globular than those of the white, and contain dark instead of light-coloured seeds. There appears to be no essential difference in their properties. Both kinds, when fresh, are glaucous, but when dry, as directed in the *Pharmacopœias*, are of a dirty

white or purplish-brown colour, have a consistence somewhat like that of paper, are without smell, and have little taste, unless long chewed, when they are decidedly bitter. Submitted to analysis, they are found to contain principles similar to those of opium, which they yield to water by decoction. They have been employed in France for obtaining morphia.

Medical Properties and Uses. Dried poppy heads, though analogous to opium in medical properties, are exceedingly feeble. They are sometimes employed in the form of decoction, as an external emollient and anodyne application, and in the shape of emulsion, syrup, or extract, are often used internally by European practitioners to calm irritation, promote rest, and produce generally the narcotic effects of opium.

PAREIRA. *U.S. Secondary, Lond., Ed.*

Pareira Brava.

"The root of *Cissampelos Pareira*." *U.S., Ed.* "*Cissampelos Pareira. Radix.*" *Lond.*

CISSAMPELOS. *Sex. Syst.* Diœcia Monadelphia.—*Nat. Ord.* Menispermaceæ.

Gen. Ch. MALE. *Calyx* four-leaved. *Corolla* none. *Nectary* rotate. *Stamens* four, with connate filaments. FEMALE one-leaved, ligulate roundish. *Corolla* none. *Styles* three. *Berry* one-seeded.

Cissampelos Pareira. Willd. *Sp. Plant.* iv. 861; Woodv. *Med. Bot.* 3d ed. p. 167. t. 65. This is a climbing plant, with numerous slender, shrubby stems, and roundish, entire leaves, indented at the top, covered with soft hair upon their under surface, and supported upon downy footstalks, which are inserted into the back of the leaf. The flowers are very small, and disposed in racemes, of which those in the female plant are longer than the leaves. The plant is a native of the West Indies and South America, and is supposed to be the source of the root, introduced into Europe from Brazil, under the name of *pareira brava*, and now recognised in the United States, London, and Edinburgh Pharmacopœias. According to Auguste St. Hillaire, however, the true pareira is obtained from another species of the same genus, growing in Brazil, and denominated *C. glaberrima*; while by Aublet it is referred to a species of *Abuta*, belonging to the same natural family.

The root comes in pieces from the thickness of the finger to that of the arm, from a few inches to two or more feet in length, cylindrical, sometimes contorted or forked, and covered with a thin, firmly adhering, grayish-brown bark. The outer surface is marked with longitudinal and annular wrinkles, and sometimes, in the larger pieces, with knotty excrescences. The interior is ligneous, yellowish, very porous, marked by irregular concentric circles, inodorous, and of a sweetish, nauseous, bitter taste. The root imparts its virtues readily to water. M. Feneulle found in it a soft resin, a yellow bitter principle, a brown substance, an azotized substance, fecula, acidulous malate of lime, nitrate of potassa, and various other salts. M. Feneulle considers the yellow bitter substance as the active principle. It is soluble in water and alcohol, and precipitated from its solution by tincture of galls. Wiggers announced, in 1838, the existence in pareira brava of a vegetable alkali, for which he proposed the name of *cissampelina*. He procured it by boiling the root with water acidulated with sulphuric acid, precipitating by carbonate of potassa, dissolving the precipitate again in water acidulated with

sulphuric acid, treating the solution with animal charcoal, precipitating anew with carbonate of potassa, drying and pulverizing the precipitate, treating it repeatedly with ether, and evaporating the ethereal solution. The alkali thus obtained may be rendered entirely pure by dissolving it in diluted acetic acid, precipitating with carbonate of potassa, and washing and drying the precipitate. (*Annal. der Pharm.* xxvii. 29.) Wiggers did not describe this alkali. It is probably the chief ingredient of the bitter substance obtained by Feneulle. Peretti of Rome and Pelletier afterwards separated an alkali from the root, which was characterized by assuming a beautiful purple colour by contact with strong nitric acid. (*Journ. de Pharm.* xxvi. 162.) In Christison's Dispensatory it is stated to be uncrystallizable, insoluble in water, soluble in ether, alcohol, and the acids, and of an intensely bitter and sweetish taste.

Medical Properties and Uses. Pareira brava is said to be tonic, aperient, and diuretic. It was introduced into European practice so long ago as 1688, and at one time enjoyed considerable reputation as a lithontriptic. It has been recommended in calculous affections, chronic inflammation and ulceration of the kidneys and bladder, leucorrhœa, dropsy, rheumatism, and jaundice. The purpose for which it is at present chiefly employed is the relief of chronic diseases of the urinary passages. Sir Benjamin Brodie has found it very useful, in chronic inflammation of the bladder, in allaying irritability of that organ, and correcting the disposition to profuse mucous secretion. Dr. T. F. Betton of Germantown, near Philadelphia, has also employed it successfully in a case of irritable bladder. (*Am. Journ. of Med. Sci.* xvii. 259.) Advantage may often be derived from combining it, in this complaint, with one of the narcotics, as opium or hyoseyamus. In Brazil, it is used in the cure of the bites of poisonous serpents, a vinous infusion of the root being taken internally, while the bruised leaves of the plant are applied to the wound. The dose of pareira brava in substance is from thirty grains to a drachm. The infusion, however, is more convenient. (See *Infusum Pareiræ*.) A tincture made by macerating one part of the root in five parts of alcohol has been given in the dose of a fluidrachm. The aqueous extract may be given in the dose of from ten to thirty grains.

Off. Prep. Extractum Pareiræ, *Lond., Ed.*; Infusum Pareiræ, *Lond., Ed.* W.

PETROLEUM. *Lond., Ed.*

Petroleum.

“Petroleum (*Barbadense*).” *Lond.*

Off. Syn. PETROLEUM. BITUMEN PETROLEUM. PETROLEUM BARBADENSE. *Dub.*

Barbadoes tar, Rock oil; Pétrole, Huile de Gabian, *Fr.*; Steinöl, *Germ.*; Petrolio, *Ital.*; Petroleo, *Span.*

Petroleum belongs to the class of native inflammable substances, called *bitumens*. These are liquids or readily fusible solids, which emit when heated a peculiar smell, burn easily, and leave a very small carbonaceous residue. They are of two kinds, one liquid, called naphtha, the other solid, denominated asphaltum. *Naphtha* is a transparent, yellowish-white, very light and inflammable, limpid liquid, which is found abundantly in Persia. It consists exclusively of hydrogen and carbon. As oxygen does not enter into its composition, it may be advantageously employed for preserving potassium. During the formation of coal gas, an artificial naphtha is ob-

tained, which by rectification is rendered equally light and limpid with the natural substance. Thus purified, it was discovered by Mr. James Syme of Edinburgh to possess the property of dissolving caoutchouc, and the solution has been usefully applied to the purpose of forming various surgical instruments of that material. It has also been employed by Mr. Mackintosh of Glasgow for giving a thin coating of caoutchouc to cloth, to render it impermeable to moisture. *Asphaltum* is solid, black, dry, friable, and insoluble in alcohol. These two varieties of bitumen often exist in a state of mixture in nature. When the asphaltum predominates it takes the name of *maltha* or *mineral tar*; when the naphtha is in the larger proportion it is called *petroleum*.

Localities. Petroleum is found principally at Amiano in Italy, at Gabian in France, upon the borders of the Caspian Sea, near Rangoon in the Birman empire, and in Barbadoes, Trinidad, and other West India islands. The wells of petroleum in Birmah are said to produce four hundred thousand hogsheads annually. The petroleum from Barbadoes is indicated as the officinal variety by the London and Dublin Colleges. The kind is not specified by the Edinburgh College.

In the United States, petroleum is found in various localities, the principal of which are on the Kenhawa in Virginia; near Scottsville in Kentucky; in Western Pennsylvania; on Duck Creek in Ohio; and on the shores of Seneca lake in New York. That found in the latter locality is usually called in this country *Seneca oil*, and similar varieties of petroleum from other native sources are known by the same name.

Properties. *Barbadoes petroleum* is a black, nearly opaque, inflammable liquid, of the consistence of molasses, unctuous to the touch, and possessing a bituminous taste, and strong and tenacious odour. Its sp. gr. varies from 0.730 to 0.878. When subjected to distillation, it yields naphtha, and leaves a solid residue of asphaltum. It is little affected by alcohol, acids, or alkalies, but dissolves in ether and in the fixed and volatile oils. It consists chiefly of hydrogen and carbon, associated with a little oxygen and nitrogen. *Rangoon petroleum* has a dark reddish-black colour, a strong, rather fragrant odour, and the consistence of lard in summer. When heated to 90°, it becomes a reddish-brown very mobile liquid. (*Christison*.) Dr. Christison obtained from it by distillation, first, a large quantity of naphtha, and afterwards a crystalline principle, which he ascertained to be identical with paraffin. In the naphtha Dr. Gregory subsequently discovered eupione. It is probable, as Dr. Christison remarks, that this petroleum is more active than the Barbadoes.

Medical Properties and Uses. Petroleum is accounted a stimulating antispasmodic and sudorific. It is occasionally given in disorders of the chest, when not attended with inflammation; but is seldom employed as an internal remedy except in the West Indies. In Germany it has been extolled as a remedy for tape-worm. Schwartz's formula in such cases was a mixture of one part of petroleum with one and a half parts of tincture of assafetida, of which forty drops were given three times a day. Externally petroleum is employed as a stimulating embrocation in chilblains, chronic rheumatism, affections of the joints, and paralysis. It is an ingredient in the popular remedy called *British oil*. The dose of petroleum is from thirty drops to a small teaspoonful, given in any convenient vehicle.

The native petroleum called *Seneca oil* is used to a considerable extent as an external application in domestic practice. It is lighter coloured, thinner in consistence, and less sapid and odorous than the Barbadoes petroleum, and probably contains more naphtha.

PETROSELINUM. *U.S. Secondary.**Parsley Root.*

“The root of *Apium Petroselinum*.” *U.S.*

Persil, *Fr.*; Petersilie, *Germ.*; Prezzemolo, *Ital.*; Perexil, *Span.*

APIUM. Sex. Syst. Pentandria Digynia.—*Nat. Ord.* Apiaceæ or Umbelliferae.

Gen. Ch. Fruit ovate, striated. Involucre one-leafed. Petals equal. Willd.

Apium Petroselinum. Willd. *Sp. Plant.* i. 1475; Woodv. *Med. Bot.* p. 118. t. 45. *Petroselinum Sativum.* Hoffman, *Umb.* i. t. 1. f. 2.; Lindley, *Flor. Med.* p. 35. Parsley has a biennial root, with an annual, round, furrowed, jointed, erect, branching stem, which rises about two feet in height. The radical leaves are compound, pinnated in ternaries, with the leaflets smooth, divided into three lobes, and notched at the margin. In the cauline leaves, the segments of the leaflets are linear and entire. The flowers are small, pale yellow, and disposed in terminal compound umbels, with a one or two-leaved general involucre, and partial ones composed of six or eight leaflets. The petals are five, roundish, and inflexed at their apex. The seeds (half fruits) are small, ovate, flat on one side, convex on the other, of a dark green colour, and marked with five longitudinal ridges. They have a strong, terebinthinate odour, and a warm aromatic taste.

The plant is a native of Sardinia and other parts of southern Europe, and is cultivated everywhere in gardens. All parts of it contain an essential oil, to which it owes its medicinal virtues, as well as its use in seasoning. The root is the part directed by the Pharmacopœia, though the fruit is at least equally efficient.

The root is spindle-shaped, about as thick as the finger, externally white and marked with close annular wrinkles, internally fleshy and white, with a yellowish central portion. It has a pleasant smell, and a sweetish slightly aromatic taste; but loses these properties by long boiling, and by the action of time. It should be employed in the recent state.

Medical Properties and Uses. Parsley root is said to be aperient and diuretic, and is occasionally used in nephritic and dropsical affections, in connexion with more active medicines. It is highly recommended by Professor Chapman. The usual form of administration is that of strong infusion. The juice of the fresh herb has been employed as a substitute for quinia in intermittents. W.

PHOSPHORUS. *Lond.**Phosphorus.*

Phosphore, *Fr.*; Phosphor, *Germ.*; Fosforo, *Ital.*, *Span.*

This substance was discovered in 1669 by Brandt, an alchemist of Hamburg; and the process by which it was made remained a secret until 1737. At first it was obtained from putrid urine, and was exceedingly scarce and costly; but in 1769, Gahn discovered it in bones, and shortly afterwards published a process by which it might be extracted from them; and his method has been followed, with but slight modifications, up to the present time.

Preparation. Calcined bones, which consist principally of that variety

of phosphate of lime called bone-phosphate, are digested for twenty-four hours with two-thirds of their weight of strong sulphuric acid, previously diluted with twelve times its weight of water. The sulphuric acid separates a part of the lime from the phosphoric acid, and precipitates as sulphate of lime; while a superphosphate of lime remains in solution. This mixture is then strained through a linen cloth to separate the sulphate of lime, and afterwards submitted to evaporation, which causes a fresh precipitation of sulphate, requiring to be separated by a new filtration. The filtered solution of superphosphate is evaporated to a syrupy consistence, and then thoroughly mixed with half its weight of powdered charcoal, so as to form a soft mass, which is dried by being heated to dull redness in an iron pot. The mass when cool is quickly transferred to a coated earthenware retort, furnished with an adopter of copper, bent downwards at right angles so as to enter a bottle with a large neck containing water, which should rise about two lines above the orifice of the adopter. The bottle is closed round the adopter by a cork, which is traversed by a small glass tube, to give exit to the gaseous products. The retort is heated in a furnace, furnished with a dome, in the most gradual manner, so as to occupy about four hours in bringing it to a red heat. Afterwards the heat is pushed vigorously, so long as any phosphorus drops into the water; and this takes place generally for from twenty-four to thirty hours. During this part of the process, the excess of acid in the superphosphate is decomposed; its oxygen combining with the charcoal, and the liberated phosphorus distilling over. A quantity of the materials sufficient to fill a quart retort will yield about a pound of phosphorus.

Properties. Phosphorus is a semitransparent solid, without taste, but possessing an alliaceous smell. When perfectly pure it is colourless; but as usually prepared it is yellowish or reddish-yellow. It is flexible, and when cut exhibits a waxy lustre. It is insoluble in water, but dissolves sparingly in alcohol and the oils, and more freely in ether. Its sp. gr. is 1.77, and its equivalent number 31.4.* It takes fire at 100°, melts at 108°, and boils at 550°, air being excluded. During its combustion, it combines with the oxygen of the air, and forms phosphoric acid. On account of its great inflammability it requires to be kept under water. When exposed to the air it undergoes a slow combustion, emitting white vapours, which are luminous in the dark. It forms with oxygen the hypophosphorous, phosphorous, and phosphoric acids, and the two isomeric varieties of phosphoric acid, called pyrophosphoric and metaphosphoric. With hydrogen it forms three combinations; one solid, a second gaseous, not spontaneously inflammable when pure, and a third, not yet isolated, generally present as an impurity in the second, which it renders spontaneously inflammable. The only medicinal combinations containing phosphorus are phosphoric acid, and the phosphates of mercury, iron, lime, and soda. Of these phosphoric acid in a diluted state, and the phosphates of iron, lime, and soda are official.

Medical Properties. Phosphorus, exhibited in small doses, acts as a powerful general stimulant; in large doses, as a violent irritant poison. Its action seems particularly directed to the kidneys and genital organs, producing diuresis, and excitation of the venereal appetite. The latter effect has been conclusively proved by the experiments of Alphonse Leroy, Che-

* Following the example of Kane and others, we have here doubled the usually received equivalent number for phosphorus. The old number made it necessary to suppose the presence of two equivalents of phosphorus in nearly all its compounds.

nevix, and Bertrand-Pelletier. From its peculiar physiological action, it is considered applicable to diseases attended with extreme prostration of the vital powers. It has been recommended in dropsy, impotency, typhus fever, phthisis, marasmus, chlorosis, paralysis, amaurosis, mania, &c. The usual form for exhibition is an ethereal solution, as directed by the Paris Codex, under the title of *Tinctura Ætherea cum Phosphoro*. It is formed by macerating for a month, in a well-stopped bottle, covered with black paper, 4 parts of phosphorus, cut in small pieces, in 200 parts of sulphuric ether, and decanting into small bottles, prepared in a similar manner. The proportion of phosphorus dissolved is about 4 grains to the ounce of ether. The dose of this solution is from five to ten drops, repeated every two or four hours, according to circumstances, in a small portion of some bland drink. It has been objected to the ethereal solution, that, upon the evaporation of the ether, the phosphorus is liable to be set free, and may inflame in the stomach. It is on this account that oil is preferred as a solvent. The *Oleum Phosphoratum* of the Prussian Pharmacopœia is made as follows. Take of phosphorus *twelve grains*; almond oil, recently prepared, *an ounce*. Melt the phosphorus in the oil by the heat of warm water, and agitate until it appears to be dissolved. The ounce of oil takes up about four grains of phosphorus; and the dose of the solution is from five to ten drops, mixed with some mucilaginous liquid. An aromatic flavour may be given to the phosphorated oil by the addition of a few drops of oil of bergamot.

Great caution is necessary in the exhibition of phosphorus, and its effects should be closely watched. It ought never to be given in substance; as, when thus administered, it is apt to produce violent irritation of the stomach. When taken in substance in a poisonous dose, two or three grains of tartar emetic should be given to dislodge it. If swallowed in the state of solution, copious draughts of cold water containing magnesia in suspension should be administered, in order to arrest the further combustion of the phosphorus, and to neutralize any acid which may have been formed.

PHYTOLACCÆ RADIX. U.S. Secondary.

Poke Root.

“The root of *Phytolacca decandra*.” U.S.

PHYTOLACCA. *Sex. Syst.* Decandria Decagynia.—*Nat. Ord.* Phytolaccæ.

Gen. Ch. Calyx none. Petals five, calycine. Berry superior, ten-celled, ten-seeded. *Willd.*

Phytolacca decandra. Willd. *Sp. Plant.* ii. 822; Bigelow, *Am. Med. Bot.* i. 39; Barton, *Med. Bot.* ii. 213. This is an indigenous plant with a very large perennial root, often five or six inches in diameter, divided into two or three principal branches, soft, fleshy, fibrous, whitish within, and covered with a brownish cuticle. The stems, which are annual, frequently grow to the height of six or eight feet, and divide into numerous spreading branches. They are round, very smooth, of a green colour when young, but purple after the berries have ripened. The leaves are scattered, ovate

oblong, entire, pointed, smooth, ribbed beneath, and supported on short footstalks. The flowers are numerous, small, and grow in long racemes, which are sometimes erect, sometimes drooping. The corolla consists of five ovate, concave petals, folding inwards, and of a whitish colour. The germ is green. There are ten stamens, and the same number of pistils. The raceme of flowers becomes a cluster of dark purple, almost black, shining berries, flattened above and below, and divided into ten cells, each of which contains one seed.

The poke is abundant in all parts of the United States, flourishing along fences, by the borders of woods, and especially in newly cleared and uncultivated fields. It also grows spontaneously in the North of Africa and the South of Europe, where, however, it is supposed to have been introduced from America. Its flowers begin to appear in July, and the fruit ripens in autumn. The magnitude of the poke-weed, its large rich leaves, and its beautiful clusters of purple berries, often mingled upon the same branch with the green unripe fruit, and the flowers still in bloom, render it one of the most striking of our native plants. The young shoots are much used as food early in the spring, boiled in the manner of spinach. The ashes of the dried stems and leaves contain a very large proportion of potassa, yielding, according to Braconnot, not less than forty-two per cent. of the pure caustic alkali. In the plant the potassa is neutralized by an acid closely resembling the malic, though differing from it in some respects. The leaves, berries, and root are used in medicine, but the two latter only are mentioned in the Pharmacopœia. The root abounds most in the active principles of the plant. It should be dug up late in November, cut into thin transverse slices, and dried with a moderate heat. As its virtues are diminished by keeping, a new supply should be procured every year. The berries should be collected when perfectly ripe, and the leaves about the middle of summer, when the footstalks begin to redden.

The berries contain a succulent pulp, and yield upon pressure a large quantity of fine purplish-red juice. They have a sweetish, nauseous, slightly acrid taste, with little odour. The colouring principle of their juice is evanescent, and cannot be applied to useful purposes in dyeing, from the difficulty of fixing it. Alkalies render it yellow; but the original colour is restored by acids. The juice contains saccharine matter, and, after fermenting, yields alcohol by distillation.

The dried root is of a light yellowish-brown colour externally, very much wrinkled, and, when in transverse slices, exhibits on the cut surface numerous concentric rings, formed by the projecting ends of fibres, between which the intervening matter has shrunk in the drying process. The structure internally in the older roots is firm and almost ligneous; the colour yellowish-white, alternating with darker circular layers. There is no smell; the taste is slightly sweetish, and at first mild, but followed by a sense of acrimony. The active matter is imparted to boiling water and alcohol.

Medical Properties and Uses. Poke is emetic, purgative, and somewhat narcotic. As an emetic it is very slow in its operation, frequently not commencing in less than one or two hours after it has been taken, and then continuing to act for a long time upon both the stomach and bowels. The vomiting produced by it is said not to be attended with much pain or spasm; but narcotic effects have been observed by some physicians, such as drowsiness, vertigo, and dimness of vision. In over-doses it produces excessive vomiting and purging, attended with great prostration of strength, and sometimes with convulsions. It has been proposed as a substitute for ipecacuanha; but the slowness and long continuance of its action, and its

tendency to purge, wholly unfit it for the purposes which that emetic is calculated to fulfil. In small doses it acts as an alterative, and has been highly recommended in the treatment of chronic rheumatism. The dose of the powdered root, as an emetic, is from ten to thirty grains; as an alterative, from one to five grains. A saturated tincture of the berries prepared with diluted alcohol may be given in rheumatic cases, in the dose of a fluidrachm three times a day. A strong infusion of the leaves or root has been recommended in piles.

An ointment prepared by mixing a drachm of the powdered root or leaves with an ounce of lard, has been used with advantage in psora, tinea capitis, and some other forms of cutaneous disease. It occasions at first a sense of heat and smarting in the part to which it is applied. An extract made by evaporating the expressed juice of the recent leaves has been used for the same purpose, and acquired at one time considerable repute as a remedy in cancer.

MYRTUS. Sex. Syst. Icosandria Monogynia.—Nat. Ord. Myrtaceæ.

Gen. Ch. Calyx five cleft, superior. Petals five. Berry two to five-celled, many-seeded. Willd.

Myrtus Pimenta. Willd. *Sp. Plant.* ii. 973; Woodv. *Med. Bot.* p. 541. t. 194. *Eugenia Pimenta*. De Cand. *Prodrom.* iii. 285; Lindley, *Flor. Med.* p. 76. This is a beautiful tree, about thirty feet high, with a straight trunk, much branched above, and covered with a very smooth gray bark. Its dense and ever-verdant foliage gives it at all times a refreshing appearance. The leaves, which are petiolate, vary in shape and size; but are usually about four inches long, elliptical, entire, blunt or obtusely pointed, veined, and of a deep shining green colour. The flowers are small, without show, and disposed in panicles upon trichotomous stalks, which usually terminate the branches. The fruit is a spherical berry, crowned with the persistent calyx, and when ripe is smooth, shining, and of a black or dark purple colour. The tree exhales an aromatic fragrance, especially during the summer months, when it is in flower.

It is a native of the West Indies, Mexico, and South America, and is particularly abundant in Jamaica, whence its fruit received the name of *Jamaica pepper*. The berries are the officinal portion of the plant. They are gathered after having attained their full size, but while yet green, and are carefully dried in the sun. When sufficiently dry, they are put into bags and casks for exportation.

Properties. The berries, as they reach us, are of different sizes, usually about as large as a small pea, round, wrinkled, umbilicate at the summit, of a brownish colour, and when broken present two cells, each containing a black hemispherical seed. They have a fragrant odour, thought to resemble that of a mixture of cinnamon, cloves, and nutmeg: hence the name of *allspice*, by which they are best known in this country. Their taste is warm, aromatic, pungent, and slightly astringent. They impart their flavour to water, and all their virtues to alcohol. The infusion is of a brown colour, reddens

litmus paper, and affords a black precipitate with the salts of iron. They yield a volatile oil by distillation. (See *Oleum Pimentæ*.) By a minute analysis, Bonastre obtained from them a volatile oil, a green fixed oil, a concrete oleaginous substance in yellowish flakes, tannin, gum, resin, uncrystallizable sugar, colouring matter, malic and gallic acids, saline matters, moisture, and lignin. The green oil has the burning aromatic taste of pimento, and is supposed to be the acrid principle. Upon this, therefore, together with the volatile oil, the medical properties of the berries depend; and as these two principles exist most largely in the shell or cortical portion, this part is most efficient. According to Bonastre, the shell contains 10 per cent. of the volatile, and 8 of the fixed oil, the seeds only 5 per cent. of the former, and 2·5 of the latter. Berzelius considers the green fixed oil of Bonastre as a mixture of volatile oil, resin, fixed oil, and perhaps a little chlorophylle.

Medical Properties and Uses. Pimento is a warm, aromatic stimulant, used in medicine chiefly as an adjuvant to tonics and purgatives, the taste of which it serves to cover, while it increases their warmth and renders them more acceptable to the stomach. It is particularly useful in cases attended with much flatulence. It is, however, much more largely employed as a condiment than as a medicine. The dose is from ten to forty grains.

PIPER. See CUBEBA.

Piper nigrum. Willd. *Sp. Plant.* i. 159; Woodv. *Med. Bot.* p. 721. t. 246. The pepper vine is a perennial plant, with a round, smooth, woody, articulated stem, swelling near the joints, branched, and from eight to twelve feet or more in length. The leaves are entire, broad ovate, acuminate, seven-nerved, coriaceous, very smooth, of a dark green colour, and attached by strong, sheath-like footstalks to the joints of the branches. The flowers are small, whitish, sessile, covering thickly a cylindrical spadix, and succeeded by globular berries, which are of a red colour when ripe.

The plant grows wild in Cochin-china and various parts of India. It is cultivated on the coast of Malabar, in the peninsula of Malacca, in Siam, Sumatra, Java, Borneo, the Philippines, and many other places in the East. We are told by Crawford, that the best pepper is produced in Malabar; but Europe and America derive their chief supplies from Sumatra and Java. The plant is propagated by cuttings, and is supported by props, or by trees of various kinds planted for the purpose, upon which it is trained. In three or four years from the period of planting, it begins to bear fruit. The berries are gathered before they are all perfectly ripe, and upon being dried, become black and wrinkled.

White pepper is the ripe berry deprived of its skin by maceration in

water and subsequent friction, and afterwards dried in the sun. It has less of the peculiar virtues of the spice than the black pepper, and is seldom employed in this country.

Properties. The dried berries are about as large as a small pea, externally blackish and wrinkled, internally whitish, of an aromatic smell, and a hot, pungent, almost fiery taste. They yield their virtues partially to water, entirely to alcohol and ether. Pelletier found them to contain a peculiar crystalline matter called *piperin*, an acrid concrete oil or soft resin of a green colour, a balsamic volatile oil, a coloured gummy substance, an extractive matter like that found in leguminous plants capable of being precipitated by infusion of galls, a portion of bassorin, uric and malic acids, lignin, and various salts. *Piperin* was discovered by professor Ærsted of Copenhagen, who considered it a vegetable alkali, and the active principle of pepper. Pelletier, however, utterly denied its alkaline nature and medical activity, and ascribed all the effects supposed to have been obtained from it to a portion of the acrid concrete oil with which it is mixed when not very carefully prepared. When perfectly pure, *piperin* is in colourless transparent crystals, without taste, fusible at 212° , insoluble in cold water, slightly soluble in boiling water which deposits it upon cooling, soluble in alcohol, ether, and acetic acid, decomposed by the concentrated mineral acids, with the sulphuric becoming of a blood-red colour, with the nitric, first of a greenish-yellow, then orange, and ultimately red. It is obtained by treating pepper with alcohol, evaporating the tincture to the consistence of an extract, submitting the extract to the action of an alkaline solution by which the oleaginous matter is converted into soap, washing the undissolved portion with cold water, separating the liquid by filtration, treating the matter left on the filter with alcohol, and allowing the solution thus obtained to evaporate spontaneously, or by a gentle heat. Crystals of *piperin* are deposited, and may be purified by alternate solution in alcohol or ether, and crystallization. The taste of pepper depends on the peculiar concrete oil or resin before alluded to, and on the volatile oil. The former is of a deep green colour, very acrid, and soluble in alcohol and ether. The volatile oil is limpid, colourless, becoming yellow by age, of a strong odour, and of a taste less acrid than that of the pepper. It consists of ten equiv. of carbon, and eight of hydrogen, and forms a liquid but not a concrete compound with muriatic acid. The medicinal activity of pepper probably depends on these two ingredients.

Medical Properties and Uses. Black pepper is a warm carminative stimulant, capable of producing general arterial excitement, but acting with greater proportional energy on the part to which it is applied. From the time of Hippocrates it has been employed as a condiment and medicine. Its culinary uses at present are too well known to require notice. Its chief medicinal application is to excite the languid stomach, and correct flatulence. It was long since occasionally administered for the cure of intermittents; but its employment for this purpose had passed from the hands of the profession into those of the vulgar, till a few years since revived by an Italian physician, to be again consigned to forgetfulness. *Piperin* has also been employed in the same complaint, and has been recommended as superior even to the sulphate of quinia; but experience has not confirmed the first reports in its favour. That in its impure state, when mixed with a portion of the acrid principle, it will occasionally cure intermittents, there can be no doubt; but it is not comparable to the preparations of bark, and is probably less active than the alcoholic extract of pepper. When perfectly pure it is inert. In those cases of intermittents in which the sto-

mach is not duly susceptible to the action of quinia, as in some instances of drunkards, pepper may be found a useful adjuvant to the more powerful febrifuge.

The dose of pepper is from five to twenty grains. It may be given in the state of the berry or in powder; but is more energetic in the latter. Piperin has been given in doses varying from one to six or eight grains.

Poivre longue, *Fr.*; Langer Pfeffer, *Germ.*; Pepe lungo, *Ital.*; Pimienta larga, *Span.*

PIPER. See CUBEBA.

Piper longum. Willd. *Sp. Plant.* i. 161; Woodv. *Med. Bot.* p. 724. t. 247. This species of Piper differs from its congeners in having its lower leaves cordate, petiolate, seven-nerved, its upper oblong cordate, sessile, and five-nerved; its flowers in dense, short, terminal, and nearly cylindrical spikes; and its fruit, consisting of very small one-seeded berries or grains, embedded in a pulpy matter. It is a native of South-eastern Asia, and is produced abundantly in Bengal and many parts of Hindostan. The fruit is green when immature, and becomes red as it ripens. It is gathered in the former state, as it is then hotter than when perfectly ripe. The whole spike is taken from the plant and dried in the sun.

Long pepper is cylindrical, an inch or more in length, indented on its surface, of a dark gray colour, a weak aromatic odour, and a pungent fiery taste. M. Dulong found its chemical composition to be closely analogous to that of black pepper as ascertained by Pelletier. Like that it contains *piperin*, a concrete oil or soft resin upon which its burning acrimony depends, and a volatile oil to which it probably owes its odour. Its medical virtues are essentially the same with those of the black pepper; but it is considered inferior to that spice, and is seldom used.

FEMALE. *Catkins* simple. *Ovaries* two. *Stigmas* glandular. *Cone* with imbricated scales, which are thin at the apex, and rounded. *Cotyledons* digitate-partite. *Leaves* solitary in each sheath. *De Cand.*

Abies excelsa. De Cand.—*A. communis.* Lindley, *Loudon's Encyc. of Plants.*—*Pinus Abies.* Willd. *Sp. Plant.* iv. 506; Woodv. *Med. Bot.* p. 4. t. 2. The Norway spruce is a very lofty tree, rising sometimes one hundred and fifty feet in height, with a trunk from three to five feet in diameter. The leaves, which stand thickly upon the branches, are short, obscurely four-cornered, often curved, of a dusky green colour, and shining on the upper surface. The male aments are purple and axillary, the female of the same colour, but usually terminal. The fruit is in pendent, purple, nearly cylindrical strobiles, the scales of which are oval, pointed, and ragged at the edges.

This tree is a native of Europe and Northern Asia. Though designated as the source of Burgundy pitch, it furnishes but a part of the substance sold under that name by the druggists. Tingley asserts that the real Burgundy pitch is obtained from the *Abies picea*, or European silver fir tree; and the same fact is stated by Fée. According to Geiger, who is probably correct, it is procured from both species. To obtain the *pitch*, portions of the bark are removed so as to lay bare the wood, and the flakes of concrete resinous matter which form upon the surface of the wound, having been detached by iron instruments, are melted with water in large boilers, and then strained through coarse cloths. It is called Burgundy pitch from the province of that name in the East of France. We are told that the greater portion is collected in the neighbourhood of Neufchatel.
